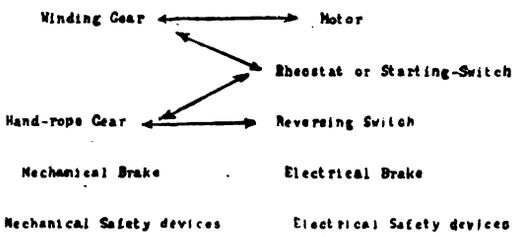
## ELECTRICALLY-DRIVEN LIFTS.*

BY F. O. HUNT.

An electrically-driven lift is very frequently a mixture of the work of two designers—the one generally a specialist on the mechanical side, and the other, too often, an electrical specialist, and nothing more. In this case, as in nearly all forms of combined plant, most of the troubles are traceable to this dual origin and the want of sympathy between the two designing minds. To use the words of a well-known lift specialist, "The electrical engineer thinks a lift is nothing but a box with a string to it," and, on the other hand, the mechanical designer is apt to consider that the electrical apparatus, other than the motor, simply performs the office of the familiar water-tap, and is, therefore, worthy of but scant consideration. It is true that the last three or four years have obliterated many of the anomalies in this direction, but as there still appears to be room for improvement it is hoped that this paper will induce discussion with that end in view.

An electrically-driven lift, in its simplest form, may have its mechanical and electrical parts tabulated somewhat as follows, where the double arrows show inter-relation between the parts thus marked :



The only electrical portion which cannot be said to have a mechanical counterpart is the rheostat, or device for reducing the value of inserted resistance as speed is attained.

*Winding Gear and Motor.*—Since the combination of these is merely a matter of direct coupling, it presents no problems essentially different from the direct driving of any other class of machinery, and has, therefore, assumed a well-defined condition of standardisation. Owing to the essential difference in economical speed of the electrical and mechanical parts, worm gear is almost universally employed as the means of combination, occasionally, where conditions of price will allow, two worms with balanced thrust being adopted.

The question of the most suitable type of motor is one which more nearly concerns us, and is a matter upon which considerable difference of opinion still exists. In some few cases series-wound motors have been used, but the practice can only be condemned as hopelessly bad. The choice lies, therefore, between shunt and compound winding. At present the

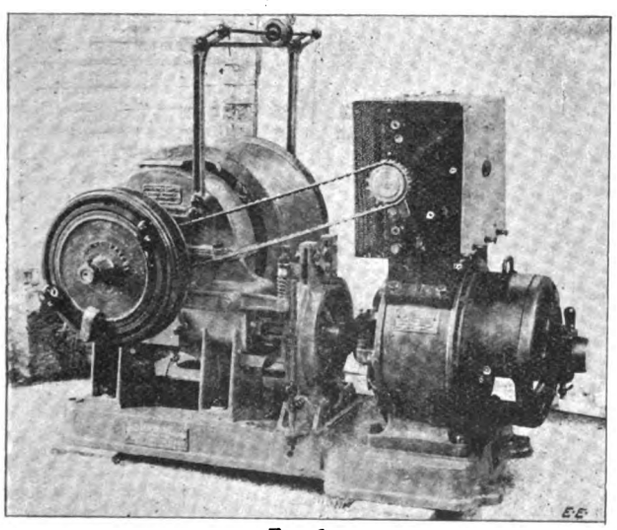


FIG. 1.

balance of opinion seems to be fairly even. The reasons given by the advocates of shunt winding are mainly greater simplicity of only one magnet winding, less space taken by insulation, and greater simplicity of the controller. Where, however, shunt winding is used, it is usually designed as if for a lower voltage than that on which the machine is to be used, and a resistance is placed in series with it. During the process of starting this resistance is short-circuited, thus making the machine take an abnormally large shunt current and producing the required extra torque to accelerate the load. Alteration of

* Paper read before the Newcastle Local Section of the Institution of Electrical Engineers, March 20.

grouping of the shunt coils on a multipolar motor is also adopted by some firms, but in either case the nett result is to obtain the required increase of ampere-turns by an addition to the shunt current taken by the motor. Seeing, however, that the greatest trouble with lifts supplied from public lighting mains is their tendency to cause fluctuation of voltage by their demand on the mains at the instant of starting, it is difficult to see how the shunt winding can be really as satisfactory as a

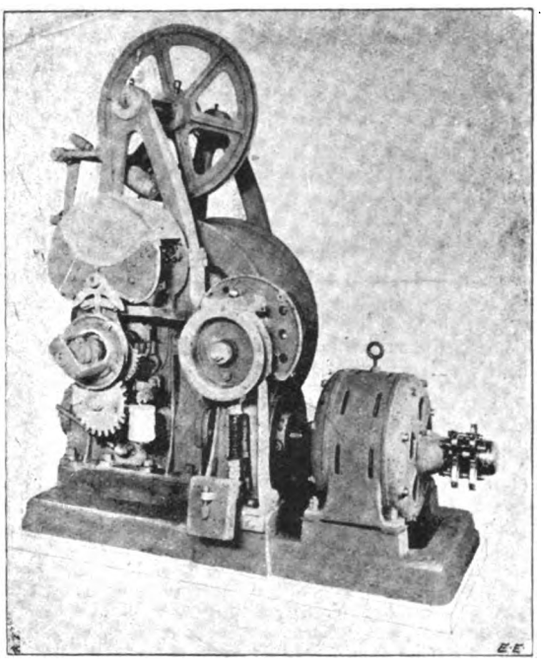

FIG. 1A.

properly designed compound-wound motor arranged to have its compound coils cut out after the process of accelerating is accomplished. The compounding merely takes the place of the last section of the starting resistance, so the complication of the controller is more imaginary than real. In this case the increase in ampere-turns is obtained by an alteration of the number of active turns, while the current value remains unchanged. In whichever way the increased excitation is obtained, it is essential that the magnetic density in the field magnet should be kept low, so that the temporary increase in excitation shall be as effective as possible in augmenting the field strength, and consequently the starting torque, of the motor.

Silence in running is also frequently a highly important matter, owing to the fact that the running machinery is located

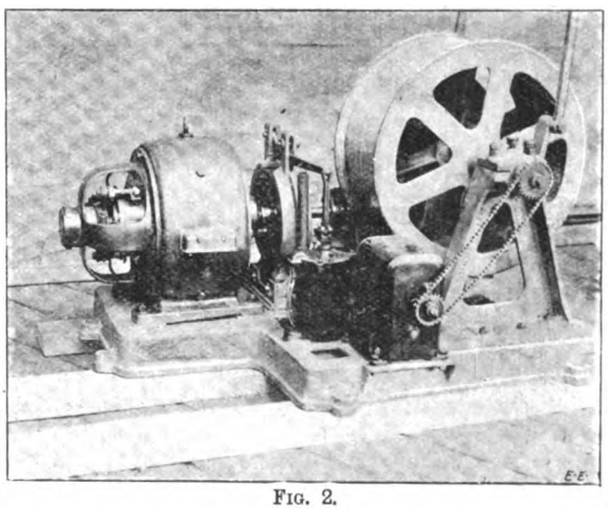

FIG. 2.

close to offices or dwelling apartments. It is, therefore, more than usually essential that the motor shall be capable of retaining a first-class surface on its commutator, and that the class of brush-holder should be such as to avoid "singing." The box type of holder so much in favour for other work is, perhaps, the most difficult to keep silent. The magnetic density in the teeth of the armature is also a matter which requires to be watched in this connection.

*Hand-Rope Gear and Reversing Switch.*—Where cheapness is an essential, hand-rope gear is at present the commonest method of operating the reversing and circuit-breaking switches. It usually consists of a more or less direct mechanical connection

Digitized by Google

between what is virtually the handle of the switch and a rope, which passes through the cage, and is, therefore, available for a

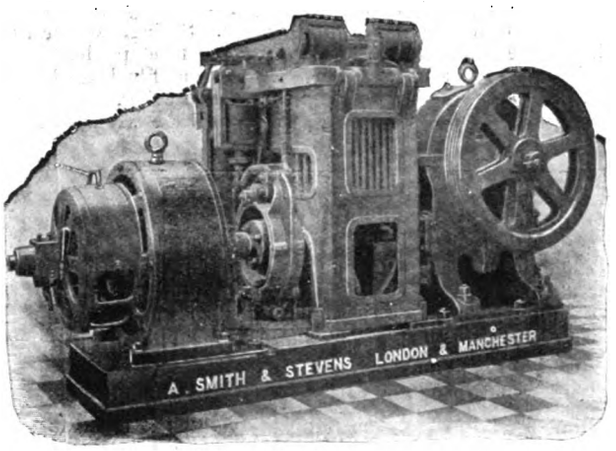

FIG. 2D.

man in the cage to set the switch or switches in any position he may desire. Examples of this method of control are shown in

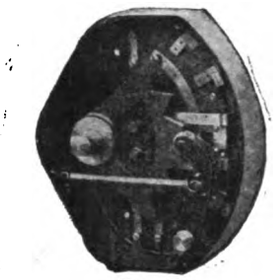

FIG. 3E.

Figs. 1, 1A, etc. (Note.—Illustrations of any one method of working have the same number, those having the same letter

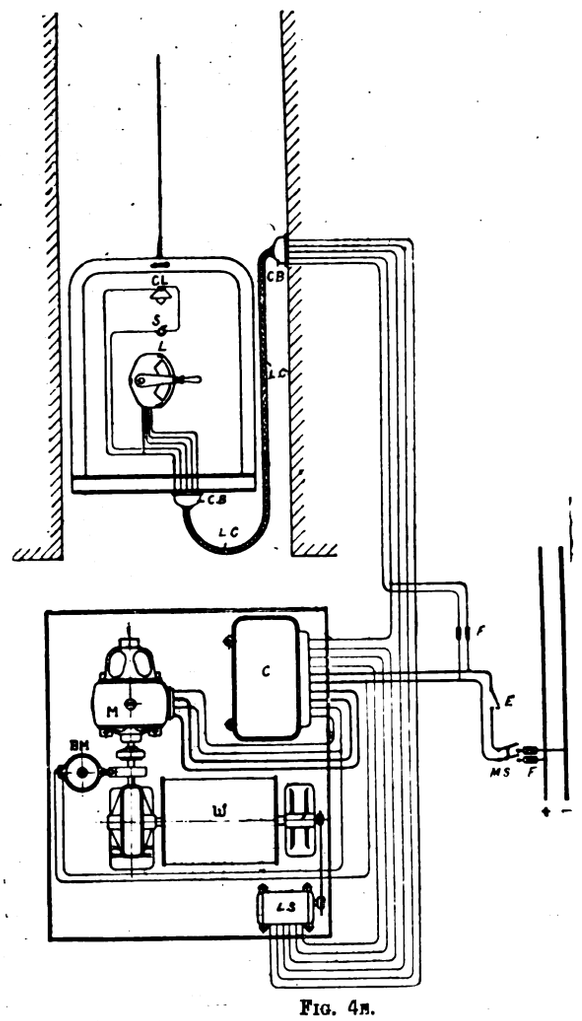

FIG. 4B.

attached are all the work of the same firm.) In many cases the reversing and circuit-breaking functions are both performed by the same switch, but there appears to be a tendency to separate the two operations. Probably this arises from the fact that

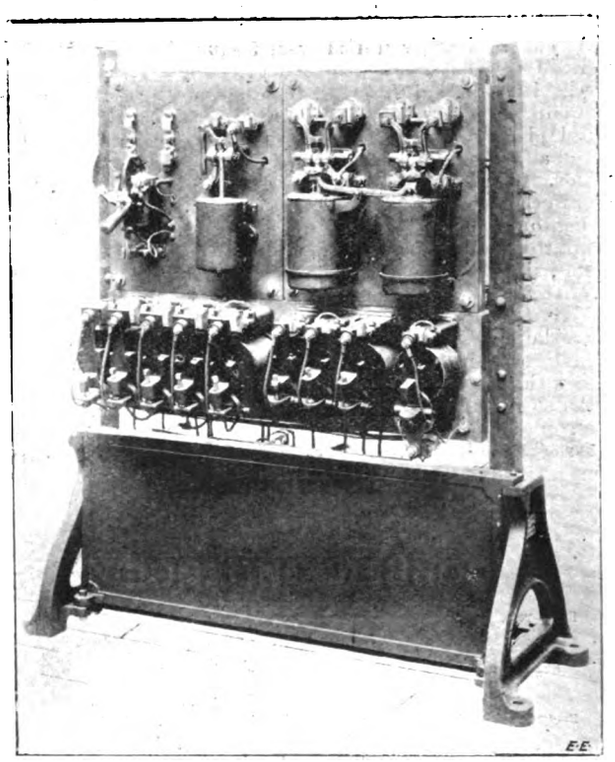

FIG. 5A.

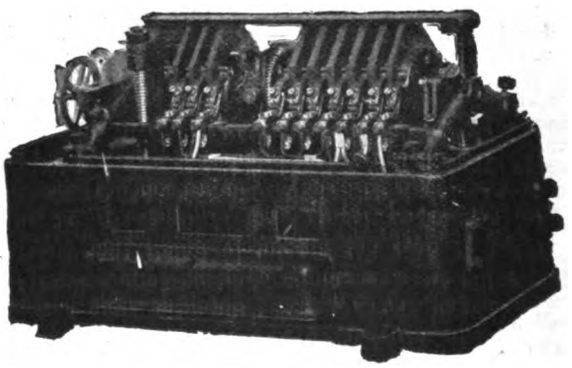

FIG. 5B.

with this arrangement it is possible to adopt more effective measures for magnetically blowing out the inevitable arc at the contacts.

Here is one of the points where differences are apt to arise between the mechanical and electrical men. The mechanical

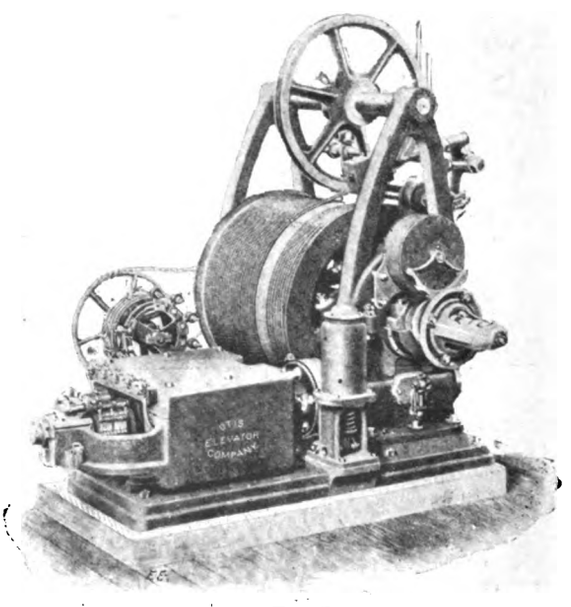

FIG. 7A.

man frequently contends that sparking at switches is purely the electrical man's concern. As a matter of fact, however, it

Digitized by Google

appears to be almost impossible, under commercial conditions, to design a switch which cannot be destroyed by sparking, unless some degree of common-sense be assumed in the working of it. Since it is impossible for the man at the rope to know the position of his switches by the use of his eyes, it is necessary that mechanical aids be given him to supply the deficiency. Even when a definite bias of position is given to

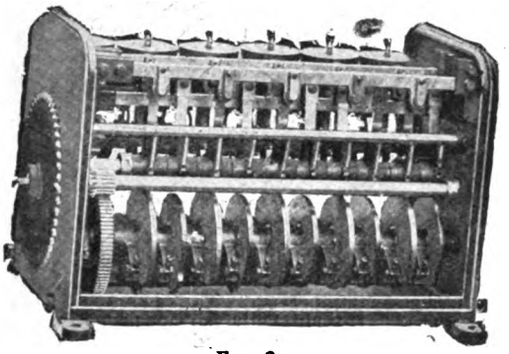

FIG. 3E.

the hand-rope, unless it is so strong as to almost overpower the man destruction of switch contacts goes on very rapidly owing to an unskilful attendant "inching" the cage to bring it exactly to a floor. Of course, switches for such service are nearly always designed with easily-renewable contacts; but it does not strike one as good engineering to make provision for vaporising brass and copper unless there is absolutely no other way out of the difficulty. This difficulty in adapting the apparently simple hand-rope idea to the operation of switches,

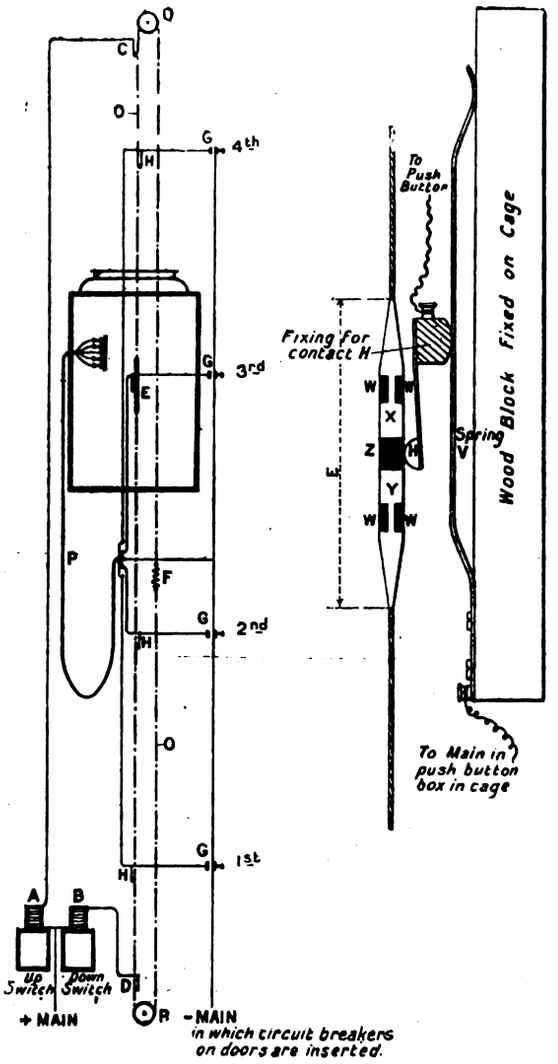

FIG. 9C.

and also the difficulty of accurate stoppage at a floor, become more and more important as the working speed of the lift is increased. In consequence, when speeds of more than 160ft. per minute are required it is now becoming usual to supersede the mechanical hand-rope transmission by an electrical method, in which the attendant merely moves a switch in the cage. Where the cage-switch method is used, the general practice is to avoid taking the actual power circuit to the cage, owing to the probabilities of trouble where heavy flexible cable is required. An independent circuit carrying a comparatively small current is led into the cage, this current being used to energise the operating solenoids of the power switches.

Figs. 2, 2D, etc., represent general views of the hoisting gear suitable for this class of control. Figs. 3E, 4E, and 5E respectively show cage switch, connection arrangements, and forms of automatic rheostat for this class of service.

Where it is desired to dispense with the services of a lift attendant, and consequently no skill on the part of the user can be assumed, the cage-switch method is supplanted by a further developed form of electrical transmission known as the "push-button" system, varieties of which are now supplied by several makers. In this system it is generally found necessary to still further reduce the current in the circuits leading to the cage or car owing not only to the difficulty of dealing with large currents on push-button contacts, but also to the similar though perhaps greater difficulty with the door contacts, which are practically indispensable on this class of work. In such cases the majority of makers insert a relay between the push-button and the circuit of the solenoid switch. Of course, this introduction of relays must mean so many more places where faults are liable to develop, but as the relays are all grouped together under cover in the motor-room, this disadvantage is perhaps not so great as at first sight appears.

Fig. 7A is a general view of such a gear. Fig. 8E is an example of the relay arrangements. Figs. 9E, 9C, indicate the arrangements of connections. Fig. 10C is interesting as an example of a push-button designed to deal with currents of the same strength as those used with switch control, and thus avoid the use of relays.

*Reversing and Circuit-Breaking Switches.*—In conjunction with the hand-rope method of working a reversing switch of the rotary type is frequently adopted, and in some cases a partial rotary motion is used, but is adapted to switches of the knife-blade type. Fig. 11C shows an example of such a switch mounted on the top of its rheostat. The straight line push-and-pull form of reversing switch, which at first sight seems especially suitable for operation by rope, appears to have only come into use for small amounts of power, such as are required on service lifts. It seems rather a difficult matter to find a

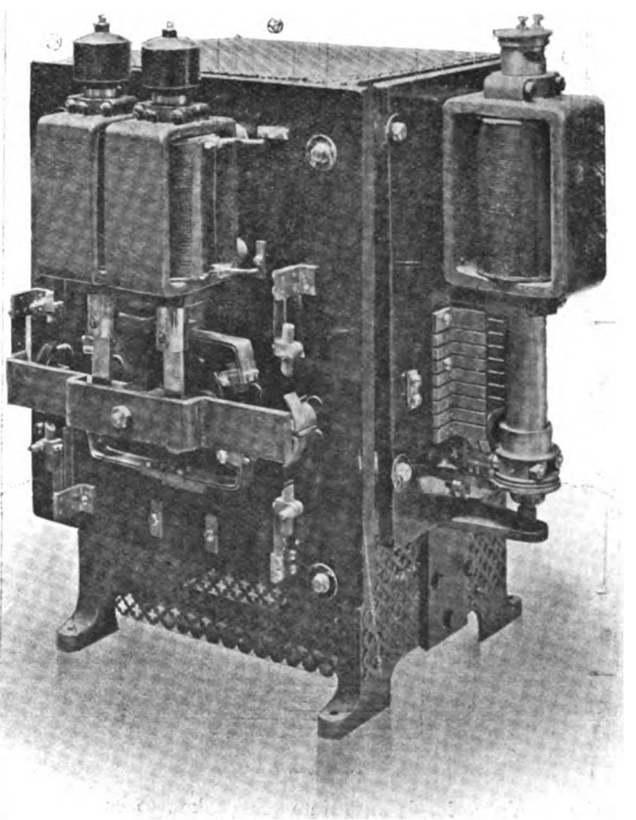

FIG. 11C.

satisfactory reason for this trend of general practice. When the hand-rope is superseded by either form of electrical transmission, it is usual to combine the reversing and circuit-breaking functions, but to divide the reversing arrangement into two switches, one of which is in use on the up travel and the other on the down journey.

*Rheostats.*—Formerly the American method of causing the

Digitized by Google

motor to mechanically provide the motion necessary to cut out its own starting resistance was very much in favour, and it is still retained by some makers owing to its inherent properties of preventing the motor being started against an overload, and also the certainty of a definite time being taken to cut out the starting resistance. It has, however, the serious drawback that, unless further auxiliary apparatus is employed, it is necessary that sufficient current to start the motor shall pass through it on the first contact stud. General practice now appears to tend in the direction of obtaining this motion electrically even when hand-rope control is in use. The time element during the process of acceleration is usually obtained by means of an air or oil dash-pot. Instances are to be seen in Figs. 11G and 11C. To avoid the use of a dash-pot, which as a piece of mechanism has doubtless received a worse character than it deserves, some makers adopt the clockmaker's striking-clock governor—viz., an air-vane geared up to run at a very high speed. An example of this can be seen in Fig. 5E. There appears, however, to be still room for improvement, as all methods of slowly-moving contact makers over studs are more destructive than intelligent hand working. What is wanted is a quick movement from one stud to the next and a prolonged pause on each stud, but an intermittent motion such as this is always difficult to obtain by mechanism that is at once cheap and reliable.

*(To be continued.)*

## PHYSICAL SOCIETY.

At the meeting of this society on March 24, Prof. J. H. Poynting, F.R.S., president, in the chair,

**Mr. W. C. Clinton** read a "**Note on the Voltage Ratios of an Inverted Rotary Converter.**" The values of the voltage ratios usually given for an inverted rotary converter make no allowance for the resistance of the armature. In this note terms due to the effect of armature resistance are introduced into the ordinary theoretical equations. The resultant voltage on the alternate-current side is found to be less than that given by the usual rule. The calculation is only made for open circuit conditions on the alternate-current side.

A paper "**On the Flux of Light from the Electric Arc with varying Power Supply**" was read by **Mr. G. B. Dyke.** The paper records the results of experiments made on the electric arc with the following objects: (1) to obtain a series of curves for alternating and continuous arcs of different lengths showing the relation between the mean spherical candle-power and the power supplied to the arc; (2) to compare the efficiencies of the alternating and continuous arcs under different conditions of arc length and power supply. The subject being too wide to deal with in its entirety, the following restrictions were made: The carbons used were 12mm. diameter cored (upper) and 10mm. solid (lower). The frequency of the alternating current was 80 cycles. The mean spherical candle-power was determined directly by means of an integrating photometer described by the author in a paper read before the society in November, 1904. Curves connecting the M.S.C.P. with the watts are given for eight arc lengths

Digitized by Google

varying from $\frac{1}{16}$in. to $\frac{1}{8}$in., for both continuous and alternating currents. These curves are found to be straight lines which cut the axis of watts at points between 200 and 400 watts. Alternate and continuous-current curves for the same arc length are found to meet the axis of watts in the same point, showing the equality of the losses by dissipation of energy in other forms than that of light. For normal arc lengths the alternating-current efficiency is about two-thirds of the continuous-current efficiency. If the arc length is reduced below $\frac{1}{8}$in., the alternating current curve rises towards the continuous-current curve until at an arc length of about $\frac{3}{32}$in. the two efficiencies practically coincide. On further reducing the arc length the alternate-current curve rises above the continuous-current curve. An approximate analysis of the case of equal efficiencies is given, the results of which give an arc length similar to that obtained experimentally.

**Dr. J. A. Fleming** congratulated the author, and referred to the practical value of the experiments. The ordinary method of comparing lamps by their M.H.C.P. was unscientific. What was wanted was the total flux of light per watt, and this important figure was obtained at once by the integrating photometer used by the author. Prof. Fleming instanced the case of a Nernst lamp and an ordinary carbon-filament lamp, pointing out that the ordinary tests indicated that the Nernst lamp was twice as efficient as the ordinary lamp, whereas a comparison of the total flux per watt showed an increased efficiency in the Nernst lamp of only 25 per cent.

**Mr. Patterson** expressed his interest in the paper, and referred to the photometrical work at present being carried out at the National Physical Laboratory. He pointed out that the variation of the light from an electric arc necessitated a great number of readings in order to get a satisfactory mean value. The photometer used by the author only integrated the light in one plane, and it would be more satisfactory to integrate in two planes at right angles to one another.

A paper "**On the Application of the Cymometer to the Measurement of Coefficiencies of Coupling of Oscillation Transformers**" was read by **Dr. J. A. Fleming**. This paper deals first with the latest pattern of instrument, called by the author a cymometer, designed for the measurement of the frequency of electric oscillations, and also the length of long electric waves. It consists of a sliding tubular condenser, consisting of two brass tubes, separated by a thin ebonite tube, the outer tube being capable of sliding off the inner tube. Parallel with this sliding condenser is placed an inductance coil or helix, of bare copper wire, wound on an ebonite tube. The outer brass tube of the sliding condenser carries a collar, which in turn carries a rod with a crutch at the end resting upon the inductance coil. The circuit of the instrument is completed by a copper bar, which joins one end of the inductance coil with the inner surface of the sliding condenser. When the outer tube of the condenser is moved by an insulating handle, the same motion reduces equally the capacity of the condenser and the portion of the inductance coil included in the closed circuit. The circuit therefore consists of a variable capacity and inductance in series. The author calls the square root of the product of the capacity and inductance in any position, the *oscillation constant* of the instrument. A scale is provided parallel with the inductance coil, on which is engraved the oscillation constant and the corresponding frequencies connected therewith by the formula

$$n = 1/2\pi\sqrt{C L}.$$

In addition to this, the instrument is provided with a vacuum tube, preferably a neon vacuum, which is connected between the inner and outer surfaces of the condenser. The instrument is used in the following manner. The copper bar is placed parallel and near to a circuit in which oscillations are taking place, and the handle of the instrument is moved, thus varying the oscillation constant, until the vacuum tube glows most brightly. Under these circumstances, it is known that the circuit of the cymometer is in resonance with that of the circuit being tested, and their oscillation constants are therefore the same, hence the scale reading gives the product of the capacity and inductance of the circuit being tested. The instrument is also provided with a rectangular wire circuit, the inductance of which is known. If this circuit is joined up with any unknown capacity and oscillations set up in it, the cymometer can be used as above, to determine the product of capacity and inductance in the circuit being tested, and the inductance being known, the capacity is therefore known also. Again, if we have any oscillation transformer, we can join up the primary and secondary circuits, so as to inductively oppose or aid one another. If we call L and N the inductance of the primary and secondary circuit respectively, and M their mutual inductance, the effective inductances, $L_1$ and $L_2$ of the two circuits joined in the two ways are respectively given by

$$L_1 = L + 2M + N. \qquad L_2 = L - 2M + N.$$

Hence we have $M = \frac{L_1 - L_2}{4}$ and $L + N = \frac{L_1 - L_2}{2}$.

If, then, either L or N is separately measured, and if the resultant inductance of the compound circuit is measured, we can find the coefficient of coupling $\frac{M}{\sqrt{L N}}$ of the oscillation transformer. The inductance of any circuit can be ascertained for the high-frequency currents by the cymometer in the following manner: The circuit to be tested is joined up in series with a known capacity, and the rectangular circuit provided with the instrument. Two measurements are then made: (1) when the inductance to be tested is included in the circuit, and (2) when excluded from it. If the observed oscillation constants under the two conditions are called $O_1$ $O_2$, then we have the following expression for the unknown inductance: $L' = \frac{O_1^2 - O_2^2}{C}$

The instrument can also be used for measuring the oscillation constant or the frequency in an open oscillating circuit, such as that of a wireless telegraph aerial, and by means of it the wave-length which is being sent out from the aerial can be measured, and also the wave length of waves being received on any aerial. The instrument can also be employed to analyse a compound oscillation taking place in a circuit and determine the component frequencies. It thus acts as an electrical equivalent of a spectroscope.

**Dr. W. Watson** expressed his interest in the paper, and said that the cymometer, on account of its simplicity, would be useful for lecture purposes. He asked Dr. Fleming if he thought that any of the anomalous results which had been obtained in determining specific inductive capacity by methods involving the mutual induction between two circuits might be due to the fact that oscillations of two different frequencies were induced in the secondary circuit. How did a change in the coefficient of coupling affect the energy transmitted to a secondary circuit?

**Prof. A. W. Reinold** said that the accuracy of the experiments depended upon the use of neon tubes, and he expressed the hope that it would soon be possible to obtain them easily. Referring to the fact that oscillations in a circuit containing capacity and inductance induced in a neighbouring circuit oscillations of two distinct periods, he asked Dr. Fleming what it was that determined the energies of the two oscillations. He also asked how, when measuring the wave-lengths of waves incident on an aerial, the fact that two oscillations were necessarily induced in the cymometer affected the utility of the instrument.

**Mr. A. Campbell** pointed out that ebonite was used as the dielectric in the sliding condenser, and asked if there was any variation in the capacity with change of frequency.

**Dr. Fleming**, in reply to Dr. Watson's question, said that undoubtedly errors might result in employing methods involving the mutual induction of two circuits for the determination of specific inductive capacities if the observer were not acquainted with the peculiarities of coupled circuits and high-frequency oscillations. The general theorem involved is that if there be two circuits, each having inductance and capacity, and oscillations are set up in one circuit by disruptive discharge in the other, then we have a compound oscillation set up in the secondary circuit which may be resolved into two frequencies which are different from the free natural frequency of each circuit separately. The theory has been fully worked out by A. Oberbeck (*Wied. Ann. der Physik*, 1895). Hence, if it were assumed that the resulting oscillation in the secondary circuit, even if it had the same natural period as the primary, was a single oscillation of the same period, an error would undoubtedly be made. Oberbeck has not given expressions for the respective energies of the two oscillations, but he has shown that the two oscillations have different damping. The coefficient of coupling determines the respective energies of the two oscillations, but Dr. Fleming said he had not yet given sufficient attention to the theoretical side of the subject to be able to furnish expressions for the energies of the two oscillations. In reply to Prof. Reinold, he said that if the mutual inductance between the aerial wire and the cymometer were small, as it was in the case of the instrument exhibited, then the cymometer only detected the oscillations which existed in the aerial. There was no creation of duplicate oscillations in and by the cymometer itself. In reply to Mr. Campbell, Dr. Fleming said that it had been shown by Prof. J. J. Thomson and others that the variation in dielectric constant with frequency was very small or even absent in the case of ebonite. That was the reason why ebonite was chosen for the dielectric tube. In the case of glass there is a large change in dielectric constant with frequency. As regards the commercial production of neon vacuum tubes, that subject was engaging his attention, and he hoped that they might soon be placed on the market. The beautiful process devised by Sir James Dewar of absorbing the common constituents of air by cocoanut charcoal at low temperatures enabled neon and helium to be prepared from the air without much trouble.

## LEGAL INTELLIGENCE.

### CITY OF LONDON LIGHTING COMPANY v. MASON, CATTLEY, AND CO.

In the City of London Court on Tuesday the plaintiffs sued the defendants for £9. 12s., for electric current supplied.

**Mr. D. M. Hogg**, counsel for the plaintiffs, said the case was a somewhat unusual one. The plaintiffs were suing for current supplied from July, 1900, to April, 1904. In 1894 the plaintiffs contracted with the defendants to give them a supply of electric light, and from then until 1900 there was no dispute between the parties. In 1900 the voltage of the company's current was changed, as also was the defendants' meter. The reading of the plaintiffs' meter was, under their Act of Parliament, conclusive evidence of the total amount of electric current consumed, in the absence of fraud. A new meter was put in in 1900, but the meter did not represent on the face of it the amount of current consumed. It was necessary to multiply the voltage registered by the meter by its constant. The defendants' old meter had had a constant of ·02. The new meter had a constant of just twice as much. Owing to a mistake in the company's office the books continued to show ·02 as the constant. The result was that for four years the defendants were only paying for half the current they used. The mistake was discovered in June, 1904, and although several letters were sent to the defendants they had not replied. There had been several mistakes of the same kind during the past year, and sometimes they were in favour of the consumer. The defendants' meter was tested by the city of London electric lighting inspector, Mr. Voysey, and the constant was proved to be ·04.

**Judge Lumley Smith**: I expect the defence is that if you make blunders you must stick to them.

**Mr. Hogg**: That is not the law.

Evidence having been given, **Mr. Harper**, for the defendants, submitted that the plaintiffs could not recover. He pointed out the

Digitized by Google

enormous inconvenience to customers of electric light current if they were to be called upon four years afterwards to pay suggested arrears. Books had been balanced and accounts closed. The defendants' contract was a contract to pay what had been ascertained in a particular way. The company had sent in their accounts, and the defendants had done what was required of them in paying them. If a meter was found to be wrong, or any calculation was inaccurate, the company could not be compelled to refund to the consumer beyond the preceding quarter.

**Judge Lumley Smith** said he thought the energy sued for had been supplied and not paid for. Therefore, judgment must be given for the plaintiffs, but without costs.

**His Honour** enquired whether the plaintiff company had ever refunded any money to anybody.

**Mr. Hogg** said they paid back the sum of £460 recently for an error the other way.

# COMPANIES' MEETINGS AND REPORTS

## WILLANS AND ROBINSON.

The half-yearly meeting of this Company was held at the Cannon-street Hotel on Wednesday, Mr. Mark Robinson presiding. Particulars of the report appeared in our last week's issue.

The **Chairman** opened his remarks with a candid statement that the figures he had to bring before the shareholders were worse than any in the history of the Company. To a great extent the unfavourable position was due to industrial depression, but a very large part of it was accounted for by the fact that the selling price per horse-power had fallen by some 26 per cent. in the same period—a fall in itself sufficient to wipe out even a very high rate of profit and turn it into a loss. The shareholders would appreciate that when the change in conditions had such an effect upon the old-established Rugby business, it was bound to exercise a great influence upon the new undertaking at Queen's Ferry, where the Company was trying to create a trade in competition with established firms, while struggling with troubles and disadvantages. Reverting to the Rugby figures, he was glad to say there were prospects of improvement in the engine business, and of some return towards remunerative prices. The directors held very hopeful views of the Company's new steam-turbine business. The success of the earlier turbines, already at work, had been remarkable. The Company was further fortunate in having control over other valuable patents for improvements in turbines, and in that connection he was sure it would be a satisfaction to shareholders to know that, in quitting the Board, Captain Sankey had left behind him a patent which the directors believed to be of great importance. Although the turbines were too new a development to be in a position to make a profit already, the directors could say with confidence that everything about it had so far gone with a success fully up to their expectations, and that their hopes were of the highest. The prospects of the large gas-engine had undergone some transition, and the directors did not now attach so much urgency to this branch. Regarding Queen's Ferry, he thought the directors could at least say that no money had been lost by restarting, and that if present appearances might be trusted the steelworks were likely to pay their full share of the necessary general charges of the place and to yield a substantial profit. Both the Admiralty and the War Office showed interest in the Company's speciality, and all the auguries were favourable. When depreciation was allowed for and the effect of some exceptional writings-down of stocks, etc., were allowed for, the real loss upon working on—perhaps he should say upon not working—was less for the past half-year than for the half-year before, not by £3,026 as the accounts appeared to show, but by as much as £8 674. Further, the loss shown was in no small part due to a breakdown of one of the large hydraulic pumping engines in October, which almost entirely stopped work in the tube works, and, indirectly, in the machine shop, for nearly half the period covered by the accounts. With regard to the proposed resolution for reducing the number of directors, the Board was of opinion that that course was eminently wise, as the duties to be performed distributed themselves to advantage among that number. It had been suggested that there should be a separate Board for Queen's Ferry, having a majority of its members unconnected with the Rugby Board. The Board could not endorse that scheme. Considerable reductions in staff and expenses generally had gradually taken effect during the last half-year.

**Mr. Anderson**, a director, said that he came to the conclusion that it would be better to work the Queen's Ferry works rather than let them lie idle waiting for a purchaser. The steelworks were now turning out 150 tons a week. There was every prospect of that department becoming a valuable part of the business.

**Mr. J. C. Peache**, director, in giving particulars of the turbine business, said that he was perfectly confident that it was an assured success.

The **Chairman**, replying to questions, agreed that more enterprise was needed at Queen's Ferry, but they had no capital for that purpose. He hoped that the Queen's Ferry might be separated from the other part of the business, but it would be necessary first to show the world what could be done there.

The report was adopted with one dissentient, and it was resolved to reduce the number of directors to five. Mr. Mark Robinson was re-elected for the usual period.

## SWANSEA IMPROVEMENTS AND TRAMWAYS.

The half-yearly meeting of this Company was held in London, Mr. C. G. Tegetmeier presiding. The report showed that the gross receipts amounted to £15 361. 11s. 2d. during the half-year ended December last, which was a decrease of £124 6s. 5d. upon the corresponding period of the previous year. The expenses amounted to £10 598 5s. 6d., an increase of £476. 10s. 10d. The profit on the half-year was £4 763. 5s. 8d., to which was added the £2,775. 8s. 2d. brought forward. The directors recommended that the sum should be allocated as follows: £1 000 to the reserve fund, £1,987. 10s. 4d. to be carried forward, and the balance in dividends at the rates of 6 per cent. on the preference shares, 5 per cent. on the second preference shares, and 2½ per cent. on the ordinary shares.

In moving the adoption of the report, the **Chairman** explained that part of the decrease in the receipts was due to the interference with traffic through alterations and extensions.

The report was adopted.

## WINCHESTER ELECTRIC LIGHT AND POWER.

At the annual meeting of this Company good progress was reported. A net profit of £5 706 was made during the year, and a dividend of 5½ per cent. per annum was declared.

## GATESHEAD AND DISTRICT TRAMWAYS.

The twenty-third annual general meeting of this Company was held last week at the London offices of the Company, Norfolk-street, Strand, Mr. C. R. Green presiding

The **Chairman**, in moving the adoption of the report, said that the total revenue for the past year showed an increase of £717, and the expenditure a decrease of £229. He thought these figures might be considered highly satisfactory, trade in the North having been very bad. Business was however, beginning to improve. The amount to be placed to depreciation and reserve fund had been increased by £500 as compared with last year. The directors had succeeded in obtaining a reduction in their rate assessment from £911 to £583, and from Jan. 1 next a new arrangement is expected to result in a saving of from £1,500 to £2 000 per annum for current.

The report was adopted unanimously.

Mr. W. J. Greer and Mr. H. S Day were re-elected directors, and Mr. J. W. Armstrong auditor at a remuneration of 20 guineas.

## DEVONPORT AND DISTRICT TRAMWAYS.

The thirteenth half-yearly meeting of this Company was held at Donington House, London, on Friday last, Mr. W. G. Bond, chairman of directors, presiding.

The report showed that the total revenue for the six months amounted to £14,713, and after deducting all expenses chargeable to revenue, there was a profit of £2 0/0. Adding to this £2,159 brought forward from the previous account, there was an available balance of £4,230 which the directors proposed should be applied: to depreciation and reserve fund, £1,500; dividend at the rate of 4 per cent. per annum, £2,649; to next account, £80. The receipts again showed an increase as compared with those of the corresponding half of 1903, but, as the directors pointed out in their last report, the lines leased from the Corporation were not yet self-supporting, the profits for the half-year being reduced accordingly. The enquiry in reference to the application to the Light Railway Commissioners for power to construct light railways in Devonport and Plymouth was held on Nov. 23 last, when the Commissioners expressed their intention of sanctioning light railways from the present terminus at Stuart-road to the Plymouth boundary in Saltash-road. Owing to pressure of other business, Mr. J. S. Rayworth had resigned the chairmanship of the Board, and Mr. W. G. Bond had been elected in his place. The number of passengers carried in the last half-year was 2,929,228, compared with 2,830,626 for the previous half-year; the average receipts per passenger 1·18d. against 1·11d.; the average expenditure per passenger (apart from line rent), ·84d. against ·79d.; and the proportion of expenses to receipts 71 per cent. against 70·7 per cent.

The **Chairman**, in moving the adoption of the report, remarked that, owing to the gradients, which involved a relatively heavy current consumption and other peculiar expenses, Devonport could never be a cheap system to work, but the directors kept a watchful eye on every item of expenditure for saving current. The building operations going on in the neighbourhood might be expected to bring more traffic.

The report was unanimously adopted.

## SOUTH WALES ELECTRICAL POWER DISTRIBUTION.

The third ordinary meeting of this Company was held at Cardiff on Saturday.

**Mr. Robert Forrest, J.P.**, the chairman, in moving the adoption of the report (particulars of which we gave in our issue of the 24th ult.), stated that the difficulty of obtaining plant from the contractors had now disappeared, but the customers had experienced the same delay in getting their plant delivered. Hence the Company were two years late in obtaining the substantial revenue which their orders and contracts would eventually give them.

The report was unanimously agreed to.

## BOURNEMOUTH AND POOLE ELECTRICITY SUPPLY.

The annual meeting of this Company was held at its London offices, Mr. A. H. Sanderson, J.P., chairman of the Company, presiding.

Particulars of the report and accounts appeared in our issue of the 17th ult. There was an increase in gross receipts of £4,756, and a

Digitized by Google

dividend at the rate of 7 per cent. was proposed. The Richmond Company is reported to be making good progress.

The report was adopted, and it was decided to increase the capital by a further issue of 10,000 preference shares at £10 each, and 10,000 ordinary shares at £10.

## RHODES ELECTRICAL MANUFACTURING.

The first annual meeting of this Company was held last week, Mr. A. L. Rhodes presiding.

The **Chairman** stated that their turnover was on the up grade, notwithstanding the fact that prices had gone down considerably. After providing for all expenses, and putting aside a reserve of 20 per cent. for goods out on approval, the net profits for the year amounted to £3,714. The report was agreed to, and it was resolved to confirm the interim dividend paid, and to sanction a final one for the current financial year of 6 per cent.

## GUILDFORD ELECTRICITY SUPPLY.

The annual meeting of this Company was held last week, Dr. F. R. Russell presiding.

The **Chairman** having generally reviewed the report (of which we gave particulars last week), the same was adopted, dividends of 6 per cent. and 3 per cent. being declared on the preference and ordinary shares respectively.

A sum of £100 was voted to the directors for their services since 1896.

## CHISWICK ELECTRICITY SUPPLY.

The report for the 12 months ending Dec. 31, 1904, states that the business of the Corporation shows a steady increase, and to meet this extensions have been made from time to time. During the year £10 937. 10s. 9d. has been expended on capital account for new machinery, mains, etc. At Chiswick, at the end of 1904, the equivalent of 29,658 lamps was wired to the mains, as compared with 25 159 at the end of 1903; and at Aberystwyth the equivalent of 11,902 lamps as compared with 11 286. Chiswick being a rapidly growing district, there is every reason to believe that the rate of progress indicated by these figures will be fully maintained. During the year the capacity of the Chiswick generating station was increased by the addition of a new 500 h.p. generating set. The station can now supply 50,000 lamps connected to the mains, and efforts are being made to get the new machinery well loaded up without delay. The economy effected by the use of the condenser, which started working a year ago, will be apparent from the accounts. The total profit made by the Corporation for the year amounted to £4,370. 10s. 8d. Out of this sum interest on debentures and loans, amounting to £1 513 8s. 2d., has been paid, £184 11s. 6d has been carried to depreciation reserve account, a balance of £2,673 being carried to the credit of profit and loss account. This latter the directors propose to apply to the payment of a dividend on the ordinary shares at the rate of 4½ per cent. per annum for the year.

## KIDDERMINSTER ELECTRIC LIGHTING AND TRACTION.

The gross receipts for 1904 total £6,300, including £2 000 received as dividend on 5,720 3½ per cent. shares held in the Kidderminster and Stourport Electric Traction Company. After deduction of increased expenses and interest on loans, the net improvement is £200. The carry forward, however, is reduced by £300, the reason being that £500 is now applied to depreciation and reserve, for which no appropriation was made last year.

## MERTHYR ELECTRIC TRACTION AND LIGHTING.

This Company's report for 1904 shows much the same result as for the previous year, the gross gain being £350. On the other hand, there is an increase of £700 in expenses—mainly on account of exceptional repairs in the lighting department. Reserve and depreciation receive £500 in lieu of £250, but there is no dividend for the £30,000 of ordinary capital, which got 2½ per cent. for 1903.

## CALCUTTA TRAMWAYS.

The report for the year 1904 shows gross traffic receipts £127,780, working expenditure under all heads £64 553, and a revenue balance, after crediting sundry receipts, of £63,513. The interest on debentures, less the amount earned by the employment of moneys in hand, has taken £14,255, and the interim dividend paid in October last £15 340, leaving £33,917, in addition to the amount brought in from the accounts of 1903, £2,351, or in all £36,268 to be now dealt with. In October last the 2,732 shares which had not been applied for by shareholders when the previous issue of capital was made were sold, and a premium of £6,557 over their par value was obtained. This sum has been credited to the depreciation fund. From the net revenue balance of £36,268 the directors propose to allocate a further sum of £8 442 to the depreciation fund, making a total addition for the year of £15,000 and bringing the amount at credit of that account to £42,792. The balance then remaining will be £27,826, from which the directors recommend that a final dividend of 5s. per share, absorbing £26,250, be now paid, which, with the interim dividend paid in October, gives a return of 8 per cent. for the year, free of tax, and the balance of £1,576 is carried forward. During the currency of the year large sums have been expended in consolidating and improving the system, and in preparing for the additional demands which will be made upon its resources to meet the requirements of the extensions shortly to come into operation, as well as those which are rendered necessary by the expansion now taking place on the existing system.

## ANGLO-ARGENTINE TRAMWAYS.

The report for the year 1904 states that the gross receipts amounted to £418 093, the working expenses to £327 528 and debenture interest and sinking fund to £16 562, leaving a net profit of £174 003. The directors recommend a final dividend of 5s. per share on the ordinary shares, absorbing £42,500, which, with the 3s. per share paid in October last, will make 8s. per share, or 8 per cent. for the year, and £5 922 is carried forward The working expenses amount to 54·42 per cent., as compared with 53·02 per cent. in 1903. The gross receipts for the year as compared with 1903 show an increase of £39,099, and the expenses show an increase of £53 102. The item "premium on debenture stock." amounting to £38,635, for some years appearing on the debit side of the balance-sheet, has been written off "cost of concessions, etc." The Board also considered it advisable to write off so much of the old reserve account as was not represented by investments, and a sum of £50,172 has been written off accordingly. The Company took over the City of Buenos Ayres Tramways Company's system on Jan. 1 last. The electrical conversion of those lines is in active progress, and will, it is expected, be completed within the next 18 months. Towards the end of last year a strike occurred amongst the employés of some of the railway and tramway companies in Buenos Ayres. This Company was not directly affected, but the result was that a general and uniform scale of revised wages and hours of labour was adopted by all the electrical tramway companies, which will entail some increase in the wages account in the current and future years.

## BABCOCK AND WILCOX.

The report for 1904 states that the net profit, after deducting depreciation on plant, etc., amounts to £289 748. To this has to be added the balance brought forward from last account, £26 820 (less £1 050 voted to the directors as bonus), making a balance of £315 519. The interim dividends to June 30, 1904 (paid Oct. 1, 1904), of 3 per cent. on the preference shares and of 8 per cent on the ordinary shares, absorbed £245,400, leaving a balance of £270,119 From this the directors recommend that the following dividends be paid for the half-year ended Dec. 31: dividend of 3 per cent. on the preference shares (from which income tax is to be deducted), £3 000; dividend of 8 per cent. on the ordinary shares (free of income tax), £242,400; and bonus of 4 per cent. on the ordinary shares (free of income tax), £21,200. After placing to the reserve fund £175 000, there remains a balance to be carried forward of £28 519. The directors report increased profits during 1904, the increase being mainly due to important export orders that were executed during the year. As some of the reserve fund now forms part of the working capital, the directors have under consideration a proposal that this should be taken from the reserve fund and added to the capital account.

## TYNEMOUTH AND DISTRICT ELECTRIC TRACTION.

The annual meeting of this Company was held in London on Friday last, Mr. W. J. Greer presiding.

The **Chairman**, in moving the adoption of the report, said that industrial depression had been responsible for a reduction in the receipts of £1 027. 8s. 10d. as compared with last year. Notwithstanding this there was a profit on the year's working of £5 965 8s. 7d. This profit had been earned by the closest possible attention to each item of expenditure, with the result that the total expenditure for the year on power, running expenses, and repairs and maintenance, showed a reduction, as compared with the previous year, of £792. 15s. 2d. The chairman then paid a tribute to the efforts of the local directors and the manager. In August an interim dividend on the ordinary shares at the rate of 5 per cent. per annum was paid. The net profit available for distribution for the year, including the balance brought forward from the previous year, amounted to £6,205. 17s. 8d. Out of this sum the preference dividends, which fell due on Sept. 15 and March 15, had already been paid, and it was proposed to apply the balance at the rate of 9 per cent. per annum on the ordinary shares for the last half-year, making 7 per cent. for the whole year, and to place, as usual, £1,500 to depreciation and reserve fund, leaving a balance of £170 to be carried forward.

The report was adopted unanimously.

## POTTERIES ELECTRIC TRACTION.

The report for the year ended Dec. 31 last, to be submitted at the meeting on the 11th inst., states that gross receipts for the year have amounted to £103 294. After deducting all expenses chargeable to revenue, including repairs and maintenance and interest on loans and debenture stock, there remains a profit of £26,705. To this has to be added £766 brought forward from the previous account, making an available balance of £27,471. The directors propose to transfer to depreciation and reserve fund £2,500, to pay a dividend on the ordinary shares of 5 per cent. for the year, and to carry forward £472. An issue of £25 000 4½ per cent. debenture stock was made in May last. The capital expended during the year amounted to £16,730, which provided for the Hartshill and Sneyd Green extensions, etc. These two extensions were opened for public traffic on Feb. 23, 1904, and July 7, 1904, respectively. With reference to the Potteries Light Railways (Extensions) Order, 1902, an application recently made to the Board of Trade for an extension of time for the construction of some of the railways authorised and for the abandonment of others has been granted. Arrangements have been made with the local authorities concerned for the Company to

Digitized by Google

construct some of these railways within one year and others within two years. It has been decided to test the traffic possibilities of routes beyond the existing tramways and light railways by means of motor omnibuses, and three such vehicles are on order and will shortly be delivered. It is proposed to commence shortly a service between Newcastle and Trentham, and it is probable that other routes will be tested in due course with a view to feeding the Company's existing lines.

### INDO-EUROPEAN TELEGRAPH.

The directors have decided, subject to final audit, to recommend the payment of a dividend for the six months ended Dec. 31, 1904, of 17s. 6d. per share, making, with the interim dividend already paid 6 per cent. for the year, and a bonus of 20s. per share, both free of income tax. They have decided also to recommend a special distribution of 15s. per share, free of income tax, out of the interest accrued during the year upon the reserve fund investments.

## NEW COMPANIES REGISTERED.

**Singapore Electric Tramways, Limited.**—Capital, $400,000 Objects: to acquire the business of the Singapore Tramways, Limited (incorporated in 1901); to adopt an agreement with the East India Construction Syndicate, Limited; to construct or acquire, equip, maintain, and work (either by electrical, steam, horse, or other power) tramways, railways, and other means of communication in Singapore and other parts of the Straits Settlements, or elsewhere.

### Liens Registered.

**Stanley Electric Carriage Company, Limited (London).**—£6,000 6 per cent. debentures, created and dated Jan. 23, 1905, charged on the company's undertaking and property, present and future, including uncalled capital, have been registered. No trustees. Holder: Major-General E. H. Sartorius, K.C.B., Old Swan House, Chelsea.

**Anglo-Portuguese Telephone Company, Limited.**—A trust deed, dated March 4, 1905, to secure £50 000 5 per cent. mortgage debenture stock, has been registered. The company covenants with the trustees to execute and do all necessary instruments and acts in Portugal to charge the company's telephone undertaking, and charges (as a floating security) its other assets, present and future, including uncalled capital. Trustees: W. R. Davis, 10, Moorgate-street, E.C., and H. Allen, 88, Chancery-lane, W.C.

**Cambridge Electric Supply Company, Limited.**—Particulars of £30 000 debentures, created by resolution dated Dec. 2, 1904, have been filed, pursuant to Section 14 (4) of the Companies Act, 1900. Property charged: the company's undertaking and property, present and future, except uncalled capital. No trustees.

## CONTRACTS FOR ELECTRICAL SUPPLIES.

**Cartagena.**—The Public Works Department, Madrid, require tenders for electrification of the local tramways.

**Christiania.**—The Post and Telegraph Department require tenders for 8,000 kilos. of 4 mm. bronze wire. Tenders by April 10.

**Erith (Kent).**—The Urban District Council invite tenders for the wiring of their car depôt and workshops. Tenders by April 17.

**Swindon.**—The Corporation invite tenders for the supply of electric motors for a period of three years. Tenders by April 17. See advertisement.

**Stockport.**—The Gas and Electricity Committee invite tenders for the supply of one 500-kw. steam generator. Tenders by April 26. See advertisement.

**Devonport.**—The Electricity Department invite tenders for the supply of one surface condenser with electrically-driven pumps. Tenders by April 18. See advertisement.

**Lisbon.**—The Municipality require tenders for installation of electric lighting; 2,000 c.p. are required for street-lighting, for which it is proposed to pay 6,000 pesetas per annum.

**French West Africa.**—The Governor-General of French West Africa, at Dakar, requires tenders for the erection and equipment of a central station at that place. Tenders by May 15.

**Brussels.**—The Government Railways require tenders for electric lamps and accessories in 21 lots. Specification No. 620 may be obtained from their Brussels office. Tenders by April 12.

**Bilbao.**—The Public Works Department at Madrid require tenders for the concession of an electric tramway in Bilbao, from the Calle de Hurtado de Amézaga to Plaza Circular. Tenders by April 24.

**Laventhem (Belgium).**—The Municipality require tenders for erection of central station, laying of mains, etc. Particulars (3s. 4d.) may be obtained from the Secretary of the Mayor of that place.

**Glasgow.**—The Corporation invite tenders for the supply of (1) main cables, (2) electricity meters, and (3) carbons for a period of 12 months from 31st prox. Tenders by April 17. See advertisement.

**Utrecht.**—The Municipal Authorities require tenders for 20 electric motors for the tramways. Specifications may be obtained at 5s. from the Municipal Secretary, Town Hall, Utrecht. Tenders by 2 p.m. on April 8.

**Nuneaton.**—The Electricity Committee of the Nuneaton and Chilvers Coton Urban District Council invite tenders for the supply and delivery of cables and joint-boxes. Tenders by April 10. See advertisement.

**Antwerp.**—Tenders will shortly be invited by the Belgian State Railways for the installation of electric light in their local railway station. Specification No. 619 may be obtained from the Government Railways Office, Brussels.

**Wimbledon.**—The Urban District Council invite tenders for the supply and erection of a 1,000-kw. steam-driven turbo-alternator, with condensing plant, high-tension switchgear, and pipework. Tenders by April 28. See advertisement.

**Glasgow.**—The Trustees of the Clyde Navigation invite tenders for electric power generating and lighting plant for Clydebank Dock. Specifications, etc., may be obtained from Mr. T. R. Mackenzie, 16, Robertson-street, Glasgow. Tenders by April 17.

**Batley.**—The Corporation invite tenders for tramway extensions—viz.: (Contract No. 14) permanent-way construction and paving; (15) overhead equipment, steel poles, etc.; (16) feeder cables, conduits, and accessories. Tenders to the Town Clerk by April 17.

**Cardiff.**—The Corporation invite tenders for the following plant for their power station on the extra high-tension system: extra high-tension three-phase main switchboard for power station; switchboards for sub-stations; motor-generators; rotary converters, etc. Tenders by April 17.

**Switzerland.**—M. R. Vontobel, of Winterthour, and M. Charles Probst, of Lucerne, have obtained a concession for the construction of a narrow-gauge electric railway from Meiringen to Gletsch. The total cost of the enterprise is estimated at £241,600; £19,600 is to be expended on rolling-stock.

**Antwerp.**—Tenders are invited for supply to the Belgian State Railways of materials for electric lighting. Tenders, by registered letter, must be addressed to the Administration des Chemins de fer de l'Etat, direction de la traction et du matérial, rue de Louvain, 13, Brussels. Plans, models, and samples are deposited at the Bureau des Adjudications, Musée Commercial, rue des Augustin, 15, Brussels, whence the special conditions of contract (No. 620) can be obtained. A copy of the general conditions and of the special conditions of contract may be examined at the offices of the Commercial Intelligence Branch of the Board of Trade. Tenders by April 12.

### RESULTS OF TENDERS.

**Matlock.**—The Urban District Council have accepted the tender of Mr. Shaw, of Sheffield, at 22s. 6d. per cwt., which is over £100 for a new cable for the tramway.

**Ilford.**—The Urban District Council have accepted the tender of the Cwmaman Coal Company, Cardiff, at 19s. 7d. a ton, for annual coal supplies for the electricity station.

**Rochdale.**—Messrs. Bruce Peebles and Co., Limited, East Pilton, Edinburgh, have received an order from the Corporation for three 120-kw. motor converters on the Peebles-Bragstad-La Cour patent system.

**London.**—The South-Eastern Railway Company have accepted the tender of W. R. Sykes Interlock Signal Company, at £7,000, to fit with electric signals the section of their line between London Bridge and Grove Park.

**Manchester.**—The Guardians of the Chorlton Union have accepted the tender of Messrs. H. Underwood and Co., Hulme, Manchester, for electric wiring of the four new infirm blocks at the new buildings at Withington Workhouse.

**Southend-on-Sea.**—The Corporation have awarded the Hart Accumulator Company, Limited, Marshgate-lane, Stratford, London, E., the contract for renewing battery at their electricity works, London-road, with 132 standard lighting type cells.

**Bolton.**—The Corporation have placed an order with the Key Engineering Company, Limited, Scottish Life-buildings, 38, Deansgate, Manchester, for "Cowan-Andrews" remote-control switchgear for their high-tension three-phase extensions, amounting to £466. 10s.

**Stoke Newington.**—Messrs. Bruce Peebles and Co., Limited, East Pilton, Edinburgh, have received the order for two 120 kw. motor-driven balancers, each consisting of a 120-kw. Peebles-Bragstad-La Cour motor converter, seven 50-kw. transformers, switchgear, etc., for stepping down 10,000-volt primary current.

**Leith.**—The Tramways Committee have accepted the tender of the British Insulated and Helsby Cable Company for the grooved wire required in the overhead installation for the new tramway system, at £1,195. 0s. 6d.; and the tender of S. Dixon and Son for the fittings to be used in connection with the wire, at £894. 7s. 9d.

**Fulham.**—The Borough Council have accepted the following tenders: Worthington Pump Company, at £1,119. 10s., for providing and fixing condensing plant (26in. vacuum); E. Green and Son, at £2,640, for providing and fixing an economiser; and the Underfeed Stoker Company, at £454, for the fitting of two existing boilers with their standard type of stoker.

**Shoreditch.**—The Borough Council have accepted the following tenders for annual supplies: J. Gibb and Co., Limited, Fenchurch-street, E.C., Contracts 1-4; Johnson and Phillips, Old Charlton, Contracts 5 and 13-23; Siemens Bros. and Co., Limited, Westminster, S.W., Contracts 10-12; Western Electric Company, Queen Victoria-street, E.C., Contracts 6-9.

**Bermondsey.**—The Electricity Committee have accepted the following tenders: Veritys, arc lamp carbons; Doulton and Co., conduits; Alexander, Duckham, and Co., engine oils; Reason Manufacturing Company and Chamberlain and Hookham, various electricity meters, indicators, and main fuses; Johnson and Phillips, meter boards, india-rubber cable jointing material, and lead-covered cables; Simplified Underground Conductor Company, compounds.

**Port Elizabeth.**—The following tenders have been accepted for the municipal electricity works recently advertised by Messrs. Davis and Soper: Tinker and Co., Manchester, boilers, superheaters, economisers,

Digitized by Google

etc.; Brush Electrical Company, engines, including turbine-generators, etc.; Western Electric Company, cables, mains, etc.; Electrical Power Storage Company, accumulators and boosters; J. H. Spagnoletti, switchboard instruments; J. Spencer and Co., crane; General Electric Company, public and street lighting; Reason Manufacturing Company, meters; G. Hatch and Co., workshops, tools, etc.

**Gloucester.**—The Electricity Supply Committee have accepted the following tenders for the supply and erection of plant for the municipal electricity works: Boilers, H. and T. Danks, Limited, Crown Boiler Works, Netherton, near Dudley, £1,751. 10s.; generating plant, Phœnix Dynamo Manufacturing Company, Thornbury Works, Bradford, £3,093; condensing plant, Mirrlees-Watson Company, Limited, Scotland-street, Glasgow, £1,669; pipework, E. Le Bas and Co., Dock House, Billiter-street, London, £1,545; feed pump, British Electric Plant Company, Limited, Alloa, N.B., £238. 10s.

**South Shields.**—The Tramways Committee have accepted the tender of Messrs. Wm. Underwood and Bro., of Dukinfield, for the construction of the permanent way and track—part 1—of the new electric tram system, for £42,903; and their tender for the construction of copper rail bonds and bonding on tramways—part 2—for £770, has also been recommended for acceptance. The Electrical Committee of the Corporation have recommended the acceptance of the tenders of Messrs. Dick, Kerr, and Co., Limited, amounting to £2,695, for generators, and for conduits, cables, and overhead equipment, amounting to £12,321; and that of Messrs. J. and H. McLaren, Leeds, amounting to £8,400, for engines. The following tenders have been provisionally accepted: Messrs. Hurst, Nelson, and Co., Limited, 10 electric tramcars with Brill trucks, £5,307; Messrs. J. T. Eltringham and Co., South Shields, boiler, £1,365; the British Thomson-Houston Company, switchboard £665, pumps, foundations, etc., £2,500.

**Grimsby.**—The Electricity Committee have accepted the following tenders (1) for electrical plant: Crompton and Co., motors; Lassen and Bjort, 52, Queen Victoria-street, water purifier; Keighley Electrical Engineering Company, Keighley, starters; and (2) for supply of oil, stores, arc lamp carbons and globes, lamps, tools, rubber goods, cables, etc., required by the electricity department of the Corporation: C. Snowden and Sons, Grimsby, wood troughing; Marsh, Son, and Co., Upper Priory, Birmingham, wires, etc.; Midland Rubber Company, Ryland-street, Birmingham, rubber goods; Western Electric Company, North Woolwich, rubber-covered cables; British Insulated and Helsby Cables, Limited, Prescot, tapes; City Glass Company, East India Dock-road, Poplar, arc lamp globes; Crompton and Co., London, arc lamp carbons; E. L. Gowthorpe and Son, London-road, Nottingham, Jena gauge glasses; Electrical Company, Charing Cross-road, London, Nernst lamps and spares; General Electric Company, Newcastle-on-Tyne, incandescent lamps; A. Cook, Old Market Place, Grimsby, picks, spades, hammer shafts, files, and sundry tools; A. Duckham and Co., Phœnix Wharf, West Ferry-road, Millwall, oils.

# BUSINESS NOTES.

## TRACTION.

**Keighley.**—Tramway tickets at the rate of 10d. a dozen are to be issued.

**Stockport.**—The work of reconstructing the Hazel Grove route was commenced last week.

**Darlington.**—The Corporation have decided to abolish ½d. fares, but to increase the number of 1d. stages.

**York.**—The company having refused an offer of £9,000 for their undertaking, the Corporation have decided to discontinue negotiations.

**Penge.**—At a meeting of the Urban District Council last week it was decided to refer the preliminary estimates for the trams to the Finance Committee.

**Aberavon.**—Consequent upon a favourable report by Colonel Druitt, the Board of Trade intimate that a provisional order for this electric tramway will be granted.

**Ilford.**—Colonel Druitt, on behalf of the Board of Trade, inspected last Friday the track over Roding Bridge, which connects the Ilford and East Ham tramways, and found same satisfactory.

**Wigan.**—The Hindley and Poolstock routes were inspected last week by Colonel Druitt, who expressed his approval, and the service was opened to the public. Other routes are nearing completion.

**West Cumberland.**—This Bill, which seeks a further extension of time for the completion of the tramways, has been passed by the Commons Committee, and will be reported for third reading.

**Sheffield.**—It is reported that, consequent upon the adoption of a universal 1d. fare, the Corporation find themselves much handicapped in regard to extensions of the system, as the profits have been greatly reduced.

**Dundee.**—The first ordinary general meeting of the Dundee, Broughty Ferry, and District Tramways Company was held in London on Monday. The proceedings, which were conducted in private, were of a formal character.

**Parliamentary Bills.**—The Tyneside Tramways, the West Cumberland Tramways, the Metropolitan Railway, and the Metropolitan District Railway Bills have been read a third time in the House of Lords and passed. The South Lancashire Tramways Bill has been read a second time. In the House of Commons the London Southern Tramways Bill has been read a second time.

**Bradford.**—The official returns for the 12 months ending March 31 show a total revenue of £328,648, compared with £197,437 in the previous year, an increase of £31,211. The total number of passengers carried during the year was 47,108 000, against some 40 000,000 in the previous year, an increase of nearly 19 per cent. A gratifying feature is the increase in the revenue per car mile from 10·421d. to 10·88d. The number of cars has been increased during the year from 229 to 239. The number of car miles run was 5,040,452, or an increase of 493 510.

**Wallasey.**—The Urban District Council's tramway returns for March show: passengers, 571,018, against 497 351 last year; car mileage, 66,858, against 63,607; receipts, £3,995, against £3,598; average per car mile, 10·74d., against 9·8d. For the year ending March 31 the figures are: car miles, 778 072, against 757,688 for the year, an increase of £20 384; passengers 7,123,870 against 6 564,493, an increase of 559,377; receipts, £38 033 against £35,147, an increase of £2 886; and average per car mile, 11·73d., against 11·13d., an increase of ·6d.

**Derby.**—The receipts of the Corporation trams for the five weeks ended March 25 amounted to £3,030, more than double the figure for the corresponding period of last year. A petition has been received from the ratepayers on Kedleston-road asking for wood paving to be laid on the whole of that road in connection with the construction of the electrical tramways, and the committee have informed the petitioners that they cannot accede to the request. The committee have decided to run all cars from the Market-place to Alvaston between 5.24 p.m. and 6.10 p.m. daily, as workmen's cars, as an experiment.

**New Zealand.**—Westrumite is being tried on a portion of the Auckland Electric Tramways Company's lines. A high wind and plenty of traffic put the preparation to the test recently, and it answered very well, although handicapped by clouds of dust blown from side streets. The engineer's report on tramway extension, adopted by the Wellington City Council, gives details of proposed lines to Island Bay, Kilbirnie, and Brooklyn. The Island Bay section consists of 6,865ft. single track, the Kilbirnie section 8 100ft., including tunnel through Mount Victoria, while the total length of the Brooklyn section is 6,000ft.

**Aston.**—At Wednesday's meeting of the Town Council a discussion took place upon the proposal of the British Electric Traction Company and the City of Birmingham Tramway Company, that the city authorities should be substituted for those companies for the purpose of working the tramways within the borough. The report of the Public Works Committee stated that the town clerk had replied to the communication informing Mr. Lycett that in the event of the city authorities being willing to take the place of the tramway companies, under the agreement of June 9, 1903, the committee would be prepared to recommend the Council to enter into such agreements as might be necessary to bring about that end. The report was adopted.

**Middlesex Light Railways.**—Sir H. Jekyll heard an application at the Board of Trade on Wednesday on behalf of the Middlesex County Council, who sought power to complete certain light railways, authorised in 1901, which had not been completed before the expiration of the period limited by the order of 1904, and with slight alterations to bring the form of the order into harmony with more recent procedure. Sir H. Jekyll after hearing counsel, said the immediate question was whether it would be desirable or permissible to alter the general law, or make any variation in the general law of rating on an extension of time order. He doubted whether the Board of Trade would be disposed to entertain such an application. The decision will be announced in due course.

**Aberdeen.**—At Monday's meeting of the Council the renewal of the permanent way between Union-street and Kittybrewster was agreed upon, the estimated expense being £12,500. After discussion and a division, the agreement between the Corporation and the Suburban Tramways Company was renewed on the same terms as at present for another year, subject to certain alterations as to the number of through cars to be run over the lines of the Corporation, the wearing by the motormen and conductors of uniforms, etc. It was remitted to the Tramways Committee to watch over the interests of the Council, and take such action as they may deem expedient, in connection with the application of the Great North of Scotland Railway Company for power to run motorcars in districts served by their system.

**Swansea.**—The electrical equipment over the North Dock and New Cut will be of an interesting character. The trolley wires over each bridge will move with the bridge contact being automatically made with the trolley wires on the land by means of automatic switches. In the case of the drawbridge there will be an arm on the Port Tennant side of the bridge, which will make contact horizontally with the land. This arm attached to the bridge is raised in a vertical position when the bridge is open, thus preventing any ships' yards from coming into contact. The equipment is arranged so that is impossible for a car, in the event of a bridge being open, to get within a dangerous distance of the opening, the current being automatically cut of for a distance as soon as the bridge moves. The borough electrical engineer designed this equipment.

**Liverpool.**—The general manager of the Corporation tramways, Mr. C. R. Bellamy, has issued his fourth annual report, which records good all-round progress. As showing the effects of the top cover it is pointed out that the average maximum number of cars for 1904 was 398 as against 407 for 1903, while the passengers carried increased by 3,585,429. The number of passengers carried in 1904 was 116 642 663; the miles run were 12,166,419, and the total receipts were £540,850, an increase over 1903 of 3·2 per cent. in passengers and 3·1 per cent. in receipts. The increase for 1904 over 1897, the last year of the late company's control, was: passengers, 203·68 per cent.; mileage, 102·33 per cent.; and receipts, 86·02 per cent. Dealing with the overhead equipment, Mr. Bellamy reports that the total cost of energy last year was £94,937, as against £80,956 for the previous year. The units consumed (including Bootle) were 20,045,629 against 17,978,718. During the year 123 people fell in front of the cars or were knocked

Digitized by Google

down, but the life-guard did its work well, only three cases of fracture occurring.

**Belfast.**—The arbitrator, Mr. Macassey, has delivered his award, and the net result is that the company will receive £304 448. The company's claim totalled £392,345, which they slightly reduced subsequently, while the Corporation put the value at £252 428. The items around which the difference occurred were the permanent way, physical junctions, depôts and machinery, cars and other vehicles, horses, harness, and miscellaneous stores. On the other items (Sydenham and Ligoniel undertakings, allowance under 1888 Act, etc.) the parties were agreed. A sum of £7,500 is awarded to the directors and other officials by way of compensation. Besides this, the Corporation take over the liability of £60,000 debentures. The costs of the arbitration devolve upon the Corporation. A short discussion ensued when the report was presented at a meeting of the Tramways and the Finance Committees, but, whilst one or two members considered the award somewhat high, the majority joined with the Lord Mayor in regarding the result as satisfactory. Good progress is reported with the work of reconstruction. The manager having advised against top covers for the present, the point was debated by the Corporation, and finally it was agreed that it should be an instruction to the Tramways Committee to look into the matter, and, if desirable, to order 20 or 30 top covers.

**Exeter.**—The new electric tramways were opened on Tuesday by the mayor (Mr. E. C. Perry) in the presence of a large concourse of people. The routes already equipped run from Livery Dole, the boundary between the city and Heavitree, to Eastgate, and thence, *via* High-street and Queen-street, to St. David's Station, while another line starting from the Cemetery-road runs through Blackboy-road and Sidwell-street to join the former at Eastgate. This line will be carried through to Dunsford Gate, St. Thomas, as soon as the removal of existing obstructions has been completed, while an extension to Cross Park, Heavitree, of the first route is rapidly being constructed. Powers have also been obtained in the Act of Parliament for the construction of tramways in other parts of the city, but these will not be proceeded with probably until it is found that the sections opened on Tuesday are a financial success. The ceremony was commenced with a satisfactory inaugural trip, in which the mayor and several members of the Corporation, with their ladies, the city electrical engineer (Mr. H. D. Munro), the consulting engineer (Mr. J. E. Waller), the chief officer of tramways (Mr. Hedertedt). Mr. A. Windsor (representing Messrs. Dick, Kerr, and Co.). Mr. Gauntlett (representing the Westinghouse Company) and a number of others participated. The tramways were subsequently declared open, and promptly gained liberal patronage. In the evening a public dinner was held at the New London Hotel to commemorate the occasion, a large company being present.

**New Car Design.**—The members of the Salford Corporation had a trial trip last week on the new single-deck car which has been built by Messrs. Dick, Kerr, and Co., according to the design of Mr. E. Hatton, late manager of the Corporation tramways. The new car, which is the first of 20 single-decked cars ordered for use in the borough, is a combination of English and American systems. It has an open centre and a closed compartment at each end, each with accommodation for 12 passengers. These closed compartments are so arranged that in the summer months the windows may be lowered and the car converted into an open car throughout. Entrance is obtained to the car by means of two steps in the middle of the vehicle, and there is a centre gangway running from end to end, which enables the conductor to collect the fares without the risks attendant upon stepping on to the footplate. Passengers in the open or centre of the car will be able to protect themselves against the cold or sudden storm by means of strong blinds, strengthened by stays, which may be used to keep out the wind and rain. The new car supplies a solution of the dry seat difficulty, for passengers may enjoy all the advantages of open-air travelling, their seating accommodation meanwhile being perfectly dry. Special provision has been made for the ventilation and lighting of the cars. Ventilators are placed in the roof, as are also the lighting arrangements, the lamps being placed in elaborate bronze fittings. The new car provides dry seats for 48 passengers, as compared with 22 inside passengers and 32 inside passengers in the present small and large bogie cars respectively.

**Dudley.**—The negotiations between the Corporation and the British Electric Traction Company in reference to the tramways in the borough seem now to show some prospect of an early settlement. So hopeless became the prospect that only a few months ago the Town Council resolved to refer the whole question to arbitration by the Board of Trade. Apparently as the result of this, the company formulated new terms, as the result of which it is now proposed to postpone the purchase of the tramways from the company for a period of 21 years as from August, 1902, when the Corporation acquired powers of compulsory purchase. The Corporation will retain the exclusive right of supplying electricity required for working all the tramways within the borough for the period named, and, in addition to a fixed annual minimum in regard to the quantity of electricity for which the company will be held responsible for payment, there will be a readjustment of the prices at which the company will be provided with the current for tramway purposes. The new conditions, if mutually agreed to, will, it is estimated, result in a considerable increase in the annual revenue from the supply of current to the company, which, it is hoped, will be applied towards the reduction of the rates. Another important condition is that the tramway to Tipton shall be electrically equipped forthwith. A communication embodying the proposals indicated was discussed by the Town Council in private the other evening, and the whole matter was referred to a sub-committee. The general impression, however, appears to be that a settlement will be arrived at without recourse to the Board of Trade.

**Metropolitan Railway.**—During the past week or so the electric service on the "Extension" has been increased, steam trains running only to stations north of Harrow. The latter, however, start from Baker-street, so that the passenger does not get the benefit of the improved traction in the tunnels, though against this is set the advantage that these trains as a rule make Willesden Green Station the first stopping place—according to the time-table, that is. Unfortunately, the breakdowns of the electric trains have been somewhat frequent of late, especially last week, but without doubt the experience on the "Extension" will be valuable when these trains run on the "Circle," where such events would be more harmful to the company, though not less annoying to the public. The new cars now in use are an improvement on the "old" ones. In place of the gates these cars have wood and glass panels, the sides of which form doors. These, by means of pulleys worked by the guard, open by sliding into recesses at the back of the end seats. By this arrangement the clanging of gates and the strong draughts of the older cars are avoided. The upholstery of the cars has also been improved, so that they may now be described as handsome. The cross seats have at the solid ends facing the gangways the company's monogram in copper, which looks very effective. The first-class cars have red carpet down the centre, but in the third-class there is no floor covering. The seat covers are not of uniform colour, and there is more walnut-coloured woodwork than in the cars first delivered. The company must be congratulated upon the appearance of the new trains.

**London United Tramways Co.**—On Monday the work of constructing the various extensions into Surrey was commenced. The route length of these lines will be over 17½ miles, and the districts covered embrace Molesey, Thames Ditton, Surbiton Kingston, New Malden, Wimbledon, Merton, and Upper and Lower Tooting, meeting the lines of the London County Council. Asked by an interviewer as to whether it would be possible, having regard to the different systems of electrification, for the company's cars to run over the London County Council's lines and *vice versâ*, Mr. Clifton Robinson said that nothing could be easier. A shoe could easily be dropped by the company's cars so as to obtain the motive power from below when it was on the London County Council's lines, and the overhead pole could be tied down. The London County Council's trams could be fitted with overhead connection. Mixed traction has been employed in Paris for some time. The electric power for working the Surrey system would not, Mr. Robinson stated, be obtained from the company's central power station at Chiswick, but would be supplied from the power station of the Underground Railways at Chelsea. The Court of Referees presided over by Mr. H. D. Greene, M.P., sat on Wednesday to consider several petitions for *locus* to be heard against the company's extension of time bill. The Wimbledon Urban District Council, the Coombe and Malden Urban District Council and the Croydon Rural District Council appeared by counsel, and contended that there had been much delay on the part of the company. Mr. Balfour Browne, K.C., opposing the applications, explained that the scheme was a very large one, extensive street widenings had to be effected, and the company were proceeding as fast as possible. All the applications were refused.

**Inquest.**—An inquest was held on Monday in the case of a little girl of three years, named Bates, who was knocked down by an electric car in Hyde-road, Manchester, while running across the roadway. The driver of the car, seeing an accident could not be averted, tried to work the gate and the lifeguard, but the latter failed to act, and the child went underneath the car, and was found lying near the motor. One or two witnesses said that the driver did all he could, and was in no way to blame. Mr. Eades (the manager of the tramcar shed) said all the cars were examined every night, and all defects entered up. In the present instance they had no record of the car being defective. The car was all right the night before, but when he examined it after the accident he found it was defective. There was a set screw missing, so that the cradle would not drop. The coroner asked whether the absence of the set screw would have been noticed when the car was examined. The witness replied in the affirmative, as the greaser would have observed it, because he would have to grease that part of the car. The only explanation the witness knew of was that the screw must have fallen out during the course of the day on which the accident happened. Mr. Eades added that on the evening following the accident he examined all the cars, and not one, other than the car which had been the subject of the accident, was out of order. The jury returned a verdict of accidental death. They considered something should be done to meet the defect resulting from the loss of the screw. Mr. Bell (representing the Corporation) said the Tramways Committee were very desirous of doing what they could to prevent accidents, and any suggestions would be carefully considered. The coroner corroborated the Corporation's willingness to always adopt useful suggestions for the operation of the cars.

**Aberdare.**—Continuing the consideration of the Urban District Council's Tramway Bill, the House of Commons Select Committee heard several witnesses in favour of the measure, including a representative of the Marquis of Bute. Mr. Owen Williams, surveyor and engineer to the District Council, described the scheme in detail. The entire length of the tramway route would be 4 miles 6 furlongs 4·7 chains. The population of the district was 47,101, 34 500 of whom lived within five minutes' walk of the proposed route. He calculated that the service would be availed of by 40,000 and from statistics gathered from other quarters he computed that the total number of passengers would be 3 600 000 per annum. In two months in 1902 the Taff Vale Railway Company only carried 1 045 passengers between Aberdare and Aberaman, the two stations with which the tram services could be said to be likely to compete, and in a certain month this year the railway company only carried 847 passengers. His estimate, including the construction and equipment of the permanent way, the construction of the power station, cars, electric motors, and car-sheds, amounted altogether to £65,495. 9s. 11d. A 10-minute service of cars would be provided. There would be 12 cars to seat 48 passengers, and most of them would be double-deck cars.

Digitized by Google

He estimated the cost of the street widenings at £12,396, and the cost in respect of the refuse destructor at £14 300. Mr. Stephen Sellon and Mr. Alfred Baker, manager of the Birmingham Corporation tramways, subsequently gave evidence in support of the Bill. Counsel for the frontagers contended that the tramways could not possibly carry the collier population, because the men had all to be at their work by a certain time, and no tramway service could possibly accommodate the whole of the men at one time. Several engineering and other witnesses gave evidence on behalf of the opposition. Mr. Hopkins, engineer, Westminster, considered the roads too narrow and the gradients too steep. Mr. Reece, barrister, Aberdare, thought there was no necessity for the line, the neighbourhood being sufficiently served by the Taff Vale Railway. Mr. R. Llewellyn, mining engineer, stated that there was little demand for the trams, and the general manager of the Taff Vale Railway gave similar evidence. At the request of the chairman, counsel for the promoters supplied an estimate of the anticipated financial results of the tramway, which showed a profit of £1,000.

**London County Council.**—The Highway Committee's proposal to spend £351,900 upon the reconstruction of the Council's Wandsworth routes for electricity was postponed last week, but came before the Council again on Tuesday. In the course of a short discussion Mr. J. Williams Benn, M.P., said that those who opposed the extension of the Council's electric system alleged that the electric tramway was doomed, and that it would soon be run off the roads by the motor 'bus. Let them suppose that this was the case, and that there were services of motor 'buses converging upon the Elephant and Castle. At the present time, in the busiest part of the day, 436 electric trams passed that spot during one hour. They would need 1,000 motor 'buses to carry the same number of passengers, and when they remembered the space occupied by these vehicles, their freedom in the course they took, to say nothing of the aroma they left behind, they would see that the idea was an impossible one. The motor 'bus cut up the roads, but although it escaped the burden imposed on the electric car, they did not fear its competition. The motor 'bus was a useful vehicle, and had, he believed, a great future, and it would be as a feeder of, and not a competitor with, electric tramcars. An amendment moved by Sir Melvill Beachcroft in favour of a reference back on the ground that the district was a suitable one in which to combine the overhead and conduit systems of traction, and so effect a saving on the capital cost, was lost, and the recommendation of the committee was then agreed to. The Council is in communication with the Metropolitan Water Board in reference to the diversion of pipes. A spirited reply from Mr. J. Allen Baker, chairman of the Highways Committee, to a statement by Mr. Richard Tilling (of Thos. Tilling, Limited), that the Council trams are not self-supporting, appears in another column. The remarkable vote in the House of Commons upon the Embankment scheme is also referred to in another part of this issue. All the metropolitan Liberal members supported the scheme. Of the Ministerialists, 11 of the London members supported it and 20 opposed it. The Premier, Sir M. Hicks-Beach, Mr. Broderick, Mr. Akers-Douglas, Sir R. Finlay, Sir E. Carson, and Mr. Walter Long were against bringing the trams over the bridges; while Sir H. Campbell-Bannerman, Sir Henry Fowler, Sir Robt. Reid, Mr. Herbert Gladstone, Mr. Winston Churchill, Mr. Labouchere, and Mr. Lloyd-George favoured the measure.

## LIGHTING AND GENERAL.

**Folkestone Electricity Co.**—The directors announce a half-yearly dividend of 7½ per cent.

**Doncaster.**—The Corporation propose to expend £7,500 in the extension of their electricity works.

**Sale of Plant.**—Particulars of a sale of second-hand electric generating sets appear in another column.

**Erith.**—Sanction has been received to the borrowing of £19,878 for the purposes of the electric lighting undertaking.

**Bath.**—Application is to be made for a loan of £9,000 to cover excesses of expenditure over the last sanction (1903) of £30,000.

**Worksop.**—The electrical engineer, in a report on a recent breakdown, says that it was caused by a dead short-circuit in a three-way box.

**Cheshunt.**—The Board of Trade have agreed to defer the question of revoking the Council's electric lighting order until the end of the year.

**Alliance Electrical Co.**—The directors recommend a dividend at the rate of 4 per cent. per annum, leaving £304 to be carried forward.

**Liverpool.**—Mr. C. R. Bellamy, in his report for the year 1904, states that 2 981 electric meters have been tested, 36 of which were rejected as incorrect.

**Calendar.**—We have recived a wall calendar, March 1905 6, from the Western Electric Company, 171, Queen Victoria-street, London, E.C. (works, North Woolwich).

**Edinburgh.**—The Cleansing and Lighting Committee have recommended that an expert be consulted as to the illuminating power of both the gas and electric light of the city.

**Glossop.**—The Lighting Committee have decided to recommend the Council to enter into a contract with the Urban Electric Supply Company for the lighting of several roads.

**Central London School District.**—The Board have decided that their schools should be placed in telephonic communication with London by means of the Post Office system.

**Direct United States Cable Co.**—The directors have declared an interim dividend of 3s. per share, being at the rate of 3 per cent. per annum for the quarter ended March 31, 1905.

**Horsforth.**—The Horsforth District Council have decided to ask for a 12 months' extension with regard to their electric lighting provisional order, which will otherwise expire this year.

**Leyton.**—An enquiry has been held into an application to borrow £5 000 for purposes of electric lighting. Mr. Lewis, the electrical engineer, gave evidence in support of the Council's scheme.

**Weybridge and Walton Electric Supply Bill.**—The Urban District Council have not been successful in their attempt to oppose this Bill before a select committee of the House of Commons.

**Brighton Telephones.**—The Telephones Committee have adopted an agreement with Mr. A. R. Bennett with reference to the terms upon which he is to continue to act as consulting engineer to the Corporation telephone undertaking, and to make periodical visits.

**Cleckheaton.**—The Electricity Committee have resolved to recommend the Council to reduce the charge for lighting purposes from 5d. to 4d. per unit, and to adopt a fresh minimum as regards the supply for power purposes, which will be also equivalent to a reduction.

**Eastern Extension, Australasia, and China Telegraph Co.**—The directors have declared a dividend for the quarter ended Dec. 31 of 2s. 6d. per share, together with a bonus of 4s. per share, or 2 per cent., making a total distribution of 7 per cent. for the year 1904.

**Dover.**—The estimate of revenue and expenditure on account of the Corporation electricity undertaking for the year ending March 31, 1906, shows receipts amounting to £17,568. After payment of all expenditure, including interest and sinking fund on the loan of £150,000, a surplus of £542 remains.

**Hampstead.**—The Council have placed a cottage at the disposal of the Electric Lighting Committee's outdoor foreman, who is to occupy the same, with coal and lighting, at a weekly rental of 8s., in consideration of his services being placed at the disposal of the Council at night in case of breakdown.

**Andover.**—The Board of Trade have issued an electric lighting provisional order with a view to the same being included in a Confirmation Bill about to be introduced into Parliament to the Corporation authorising them to supply electrical energy for the public and private purposes within the borough.

**Norwich.**—An enquiry was held on Tuesday into the application of the Town Council for sanction to borrow £30 000 for electric lighting purposes. The Town Clerk in his evidence said that whereas in 1902, the last year of the company, there were 2 635 consumers, there were now 3 277, and the 8-c.p. lamps equivalent was 125,700 now against 99 180 then.

**Stock Exchange.**—Applications have been made to the Stock Exchange Committee to allow the Newcastle-upon-Tyne Electric Supply Company's 57 009 ordinary shares of £5 each, fully paid, 17,991 ordinary shares of £5 each, 57,009 5 per cent. preference shares of £5 each, fully paid, and 17,991 5 per cent. preference shares of £5 each to be quoted in the official list.

**Metropolitan Asylums Board.**—Mr. A. C. Scovell presided on Saturday at the meeting of the Board at the offices, Victoria-embankment. The Local Government Board wrote sanctioning the proposal to enter into a contract with a selected firm or firms for the installation of electric lighting, telephone, and fire-alarm systems at the Southern Hospital without first advertising for tenders.

**Telephones in Cab Shelters.**—The chief constable (Mr. McKenzie) has submitted a report to the Cardiff Cabs Committee as to the progress of the installation of telephones in three cab shelters to be placed by the Corporation in various streets. The penny-in-the-slot arrangement is to be adopted, and the general public will be permitted to enter the shelters to telephone to other shelters and for general purposes.

**Greenock.**—The Corporation have agreed on a revised scale of charges for electricity for the next five years, subject to certain conditions on the eve of settlement. The rates are as follows: first 500 000 units at 1½d. per unit, next 200,000 units at 1¼d. per unit, then 200,000 units at 1d., and anything further at ·85 d. per unit. The revenue from these sources is expected to amount to about £5,000 per annum.

**London Gazette.**—The partnership between Edward Bakewell and Henry Nelson Bundy, carrying on business as electrical engineers at 50, Narrow-street, Peterborough, has been dissolved by mutual consent. The partnership between George Charles Ching, Henry George Kettle, and Charles John Edwards, carrying on business as motor manufacturers and electrical engineers at Ipswich, has been dissolved by mutual consent.

**Loughborough.**—The Electricity Committee have resolved that if the consumption of electricity by any consumer exceeds 1 500 units per quarter a charge of 4d. per unit be made, the ordinary price of 5d per unit to be charged for a consumption below that quantity. The electrical engineer has been requested to make enquiries as to the probable demand by manufacturers and others with a view of a revision of the charges for power purposes.

**Halifax Telephones.**—The Corporation and the Chamber of Commerce are addressing to the National Telephone Company a joint complaint with regard to the insufficiency of the service between Halifax and Bradford. It is pointed out that in Halifax there is only one central station for all this large town, and that the company ought either to extend the area in which they gave their ordinary rates or to provide a second station, as in Bradford.

**Oriental Telephone and Electric Co.**—The directors have resolved to recommend the payment of a dividend at the rate of 6 per cent. per annum on the preference shares for the half year ended Dec. 31, less income tax, and a final dividend of 3½ per cent. on the ordinary shares issued, free of income tax, making a total of 6½ per cent. for the year. The share transfer books of the company will be closed from April 17 to 28, both days inclusive.

Digitized by Google

**Aberdeen.**—The Town Council have decided that the rule as to disconnecting the electricity demand indicator should be altered so as to provide that consumers on any particular occasion (but not exceeding one in each month, and three days at one time) requiring an extra supply of electricity, might, by giving the Corporation 24 hours' notice in writing, have arrangements made whereby their indicators would not register the demand on the occasion so notified.

**Electrical Accessories.**—We are informed that the Lister Electric Manufacturing Company, Dursley, have just purchased the entire business of Headley, Limited, recently carried on at Moresk Mills, Truro, with branches and agencies at London, Edinburgh, Manchester, and elsewhere. The stock-in-trade, plant, and tools are now being transferred to the Dursley Works, where the business will in future be carried on under the direct personal supervision of Mr. Headley.

**Derby.**—The following estimate of expenditure on capital account for the year ending March 31, 1906 has been approved by the Electric Lighting Committee—viz.: drill, lathe, and smith's hearth. £100; one 500 kw. turbine and dynamo and condensing plant, £4 400; piping £150; foundations, £100; mains, £3 000; services, £600; switchboard panels, £300; meters and instruments, £400; transformer chamber and switchgear, £50; contingencies, £500—total, £9,600. A loan is required.

**"Robertson" Electric Lamp Fire Brigade.**—The members of this important branch of the lampmaking staff at Brook Green held a Cinderella dance in the large hall of the Brook Green Works on Saturday evening, March 25 and judging by the success of the proceedings, it is likely to become an annual institution. About 300 friends and visitors were present, taxing to the full the capacity of the excellent hall provided by the firm for the recreation of the employés of the Robertson Electric Lamp Works.

**Wellington (N.Z.).**—The installation of the metallic return system for the telephones in Wellington will probably occupy two years. The material is in hand, and the work will begin at once. The tender of Messrs. Trevor and Sons, of Wellington, has been accepted by the Public Works Department for the erection of new post and telegraph offices at Palmerston North. The Public Works Department have accepted the tender of James Trevor and Sons (£5,254) for the erection of the Palmerston North Post Office.—*N.Z. Mining, etc., Journal.*

**Hammersmith.**—The Council on Wednesday agreed that, from and after the reading of the meters at the end of the next September quarter, the present method of charging for the supply of electricity for private lighting upon the maximum demand indicator system be abolished, and that in lieu thereof a flat-rate charge of 3d. per unit be adopted. The premises of 21 additional consumers, representing a maximum of 373 8-c.p. lamps, have been connected to the mains, and 20 consumers have been disconnected. The present number of consumers taking current from the mains is 1 563.

**French Cable in Venezuela.**—A Reuter's telegram from Caracas, April 2, says that the grounds for the Court's recent decision annulling the French cable concession were that the cable company had contracted to lay a submarine cable between La Guaira and the United States, but had built a land line across San Domingo, where repeated revolutions had interrupted communication, causing loss to Venezuelan commerce. The company had also contracted to construct a national coast-wise line, but had made the line international from Puerto Cabello to Coro by touching at Curacao.

**Middlesbrough.**—The Council have referred a notice from the Cleveland and Durham Power Company of intention to lay cables in various streets to the electrical engineer for report. The engineer (Mr. Taylor) in his last report stated that the number of units sold was 116,336, against 61,860 in March last year. The revenue was £1,478, against £860, and the works cost £341, against £229 in March last year. The total cost of production for the month was £497, or 1d. per unit, compared with ·32d. per unit last year. They had thus made a profit on the month of £980, exclusive of interest and redemption.

**St. Pancras.**—The Borough Council last night decided to accept the offer of the Underground Electric Railways Company of London, Limited, respecting the supply to their eight stations in the St. Pancras area. The company will take the supply continuously for 23 hours each day throughout the year, which is practically a 100 per cent. load factor, and will guarantee a minimum consumption at each station of 5 000 units per annum, for a period of five years. They will pay 1¼ d. per unit, which is the same as they have agreed with the Islington Borough Council for the supply to their stations in the Islington district.

**Municipal Wiring.**—A deputation from the Sheffield Electrical Contractors' Association complained to the last meeting of the Sheffield City Council against the competition of the Corporation's wiring and fitting department. Specific instances in which there was cause for complaint were pointed out, and a demand was made that the Corporation's department should be closed altogether. We understand that in reply it was stated that it would be impossible to close these departments, as this would involve too big a loss to be put upon the rates. A promise, however, was made to investigate the specific cases which were made in confidence.

**Holborn and Finsbury Exhibition.**—The exhibition, which closed on Wednesday after nearly three weeks' run, has been successful to a degree that one would hardly have anticipated. The exhibitors are unanimous in their enthusiasm in regard to the really good business results. A big amount of business has already been transacted, in some cases to figures of considerable amount, and the number of enquiries from influential firms have been most gratifying. The power section especially has come to the fore in this respect, and the County of London Company have every reason to anticipate considerable and immediate increase in their already heavy power supply. A dinner is being arranged by the exhibitors, and will take place early next week.

**Electric Main Dangers.**—In the House of Commons on Tuesday Mr. Bonar Law said the attention of the Board of Trade had been called to an action in which the Manchester Corporation had to pay for damage caused by a fire which had resulted from an explosion in one of the Corporation's mains. An improved system, in which the mains were separated into sections connected by suitable fuses, and whereby the difficulty in localising leakage and consequent risk were much reduced, had received the consideration of the Board of Trade, and had been adopted in all undertakings established during the last two years in London and elsewhere. He understood that the improved system had been applied voluntarily to many existing undertakings in London.

**Coventry.**—Business at the electricity works during the past year, which closed at the end of March, has been of a steadily increasing character. According to the chairman of the committee, as much current is now being sold at night as during the day. This is due to three causes: (1) the reduction in the price of electricity; (2) the installation and hiring out of motors; (3) the fact that many people who hitherto have only used the current for lighting purposes in certain parts of their premises, now have it installed throughout. An increasing number of motors are being used by manufacturers, one of the largest firms in Coventry having discarded their steam-engines for driving machinery, and are now using electric motors hired from the department. The extensions at the electricity works are making good progress.

**Eastbourne.**—The annual cost of lighting Orchard-road by means of ½-ampere Nernst lamps is estimated at £3. 10s. 2d. per lamp, including interest and sinking fund charges on the capital expenditure, while the annual cost of a gas lamp is, it is stated, £3. 5s. The above figures are exclusive of lighting and extinguishing. Three specimens of a special type of fitting for improving the lighting by incandescent lamps will be supplied by the Reason Manufacturing Company on the condition that no charge for them will be made if they do not give satisfaction. Further enquiries are to be made with regard to the system to be adopted for laying new electric mains at the East End. The chief details in connection with the proposed laying of the two high-tension feeders from the works to the town and the provision of spare ducts in the conduits for future extensions are those in reference to the best type of conduit to lay. The total estimated cost is £3,518.

**Hastings.**—In the note which appeared on p. 464 of our last issue respecting the "Luna" arc lamp at Hastings we regret to say there is a serious error. These lamps, as is well known, are manufactured by the Electrical Company, of 121 125, Charing Cross-road, W.C., and not by the firm mentioned in the note in question. We understand that experiments were made at Hastings on a number of types of flame lamps, and that the Luna lamp was on trial near the Memorial. The Electricity Committee and Mr. Ferguson were so pleased with the results obtained that they have adopted this type of lamp for their street-lighting. The first order will comprise between 50 and 100 lamps to be used in lighting the front. In this work they will replace an older type of open arc, giving much more light with a smaller consumption of electrical energy. These lamps have also been on competitive trial at Sheffield, where they have been adopted by Mr. Fedden for the lighting of the town hall.

**Burslem.**—Mr. Ashton Bremner, the borough electrical engineer, has issued a descriptive pamphlet in view of the approaching completion of the electrical works. The works include also a destructor plant. As a result of negotiations between the Burslem and Tunstall Councils, application has been made to extend the area of supply to Tunstall and the necessary provisional order only awaits the formal consent of Parliament. Arrangements are now being made to ensure a supply over the extended area of Burslem, Wolstanton, and Tunstall. The cost of the scheme is estimated at £24,000. The scale of charges for current will be as follows: for lighting 5d. per unit, or, at the option of the consumer, on the maximum demand system of 7d. per unit for the first hour each day and 2d. per unit afterwards; for motors, 2d. per unit, or, at the option of the Corporation, 10s. per quarter per horse-power installed and 1½ d. per unit. It is expected that the supply will commence about Sept. 1.

**City Telephone Fire.**—Dr. F. J. Waldo on Tuesday opened an enquiry at the City Mortuary, under the City Fires Inquest Act, with reference to the fires which occurred simultaneously at the premises of the National Telephone Company in Oxford-court, Cannon-street, and Mansion House chambers, Queen Victoria-street. It will be remembered that the telephone system in the Metropolis was seriously affected for some days by the outbreak. The Coroner said the Telephone Company had their Bank exchange in the upper floor of Mansion House chambers. There the fire broke out at two o'clock on the morning of Tuesday, Feb. 28, and destroyed two little wooden structures on the roof known as the test-room. The fire at the Oxford-court premises of the company broke out in the telephone distributing room on the topmost floor. The distributing room was closed at the time. It appeared from what he had been informed that some tests were then being carried out on the Inner Circle on the District Railway, which rendered necessary some alterations in the telephone wires in the tunnels, and the conductor rails were charged. One of the telephone cables came into contact with the live rail, an arc occurred, and the lead sheeting was melted off the cable. The telephone wires, used to carrying only a voltage of 22 or 24 volts, received the current of 600 volts from the rail. That current was carried to the test-room of the Bank exchange and the cable-room, and caused fires at both places. The Board of Trade had intimated that the fire "did not appear to be a matter in regard to which the Board of Trade have any power to order an enquiry," and he had decided, therefore, to hold an inquest. After some evidence had been given, the enquiry was adjourned.

Digitized by Google

**Bermondsey.**—At the last meeting of the Borough Council the Electric Lighting Committee presented a report in reference to an excess charge of £6,946. 11s. 6d. in excess of £11,078 estimated for cost of mains laid in Rotherhithe. The details of expenditure were: contract with cable company and cables ordered, £10 268. 5s. 1d.; look crossings, £2,652. 12s. 9d.; labour, £5,163. 13s. 8d.—total, £18,024. 11s. 6d. A sum of £2,652. 12s. 9d. of the total excess expenditure had been passed by the Council for the work involved in taking the mains across the Surrey and Lavender Docks, the balance of £4,293. 18s. 9d. was attributable to the greater expense involved in opening up and reinstating the roadway, especially in Union-road, where the conduits had to be laid at a depth of 4ft., and in crossing Southwark Park-road at 18ft. deep. Extra labour and tackle had been required in supporting the large number of pipes exposed in excavations. A large number of extra brick chambers had also to be provided, additional labour in pulling cables, and the difficulties occasioned by wet weather.

**Lancaster.**—The Mayor, in moving the adoption of the Electricity Committee's minutes at the last Town Council meeting, said that there had been a falling off in the total consumption and the amount received for the sale of current, principally on account of tramways, but there had been a slight increase in the consumption for lighting purposes. As a set off they had reduced the price of electricity for power from 3d. to 2½d. per unit, and the charge to the tramways by 5 per cent. from last September. The estimates for next year showed a profit of £2574, and the actual profit last year was £2521, which they had placed to the reserve fund. The estimated profit was £729, so that they had realised £200 short of the estimate. It was pointed out that the Tramways Committee obtained the current for 2d. per unit less 5 per cent, whereas the current generated at the works cost 2·6d., so that the committee were supplying the tramways absolutely below cost. Mr. Frank Shaw, of the Technical Schools, Manchester, and lecturer in electrotechnics at the Storey Institute, delivered a popular lecture on "Electric Lighting and Lamps" at the Storey Institute.

**London County Council.**—On Tuesday tenders were received (*a*) for the manufacture, etc., of eight induction motor-generators for tramways sub-stations; (*b*) for the supply, etc., of general wiring material at the Greenwich electricity generating station; (*c*) for the supply, etc., of low-tension cables, cable boxes, etc., at the Greenwich electricity generating station. It was agreed to lend the Hackney Borough Council £11,085 for electric lighting and street-lighting. The Housing Committee recommended that an agreement be entered into with the County of London Electric Supply Company, Limited, for the supply, on the automatic prepayment system, of electric light to the cottages in course of erection on Section B of the Totterdown Fields Estate; that the agreement do provide for the wiring of the cottages before the walls are plastered, subject to the work being carried out to the satisfaction of the Council, and to the company bearing such additional expense as may be due to the work being done in that manner; that the solicitor do prepare, and obtain the execution of, the agreement; and that the seal of the Council be affixed to the agreement when ready.

**Hull Telephones.**—At the last meeting of the Hull and District Chamber of Trades, the following letter was read from Sir H. Seymour King, M.P., in reply to a resolution of the Council recommending that the National telephones should only be purchased on terms which will permit of the low rates of the competitive system being maintained: "I am afraid that your Council hardly appreciate the position in which the Government were *vis-a-vis* the Telephone Company. As a matter of fact, Parliament is under an obligation to purchase the telephone system at the expiration of the license, or else to renew the license, which most people think would be a most unfortunate and unbusiness-like thing to do. Of course, the agreement with the Telephone Company contains no guarantee that cheaper rates shall be charged. Why should it? It has nothing to do with purchase from the Telephone Company; it is a question between the Government and the country, as to which Parliament will no doubt use the proper pressure through the representatives of the towns in due course. The Government is bound to purchase at the value of the plant on tramway terms at the expiration of the license. No other terms would be possible." The engineer has been authorised to advertise for tenders for the cables required in connection with the extensions.

**Fire Pumping Plant.**—Messrs. Gwynnes, Limited, engineers, of London, have been entrusted with an order from Lord St. Levan, of St. Michael's Mount, for probably the most up-to-date fire pumping plant in the country. It consists of a set of electrically-driven centrifugal pressure pumps in duplicate, automatic in action, placed in the engine-room, situate about 400 yards from the castle. An electric storage battery, always charged day and night, will be fitted, of sufficient size to run either fire pump for one hour. After this time arrangements are made whereby the pumps can be driven continuously from the generating plant. In the castle itself, in convenient positions, will be situated 12 hydrants, each with a long length of hose and nozzle, ready for immediate use; also, in convenient places, nine fire-alarm switches. It will only be necessary for any one of these switches to be moved over to start the first set of the electrically-driven fire pumps in the engine-room. The same switch will start electric bells ringing over the other eight switches in the castle, and it will also ring an electric bell in each of the cottages at the bottom of St. Michael's Mount. The fire plant, electric switches, and bells are all in duplicate, and if by chance, therefore, it is found that the first plant is out of order, it will only be necessary for one of the attendants to start one of the other nine switches controlling the other set, when the second set will immediately come into operation. Arrangements have been made whereby two hydrants can be turned on practically to any part of the castle should a fire break out.—*Cornwall Gazette.*

**Islington.**—At to-night's meeting it will be proposed (1) that in response to an application from the Hornsey Town Council that the south-west side of Stroud Green-road be lighted by 10 arc lamps at a cost of £800; (2) that a low-tension main be laid in the City-road at a cost of £50; and (3) that an expenditure of £4 500 for mechanical stokers, be agreed to. The committee recently made some tests at the electric lighting station with mechanical stokers of an improved type, and have submitted a report stating that small bituminous coal at the present price of 9s. 7d. per ton can be used in the furnaces with almost as good an evaporative efficiency as can be obtained by hand firing on the other boilers with Welsh coal at 16s. 3d. per ton. They consider it desirable, however, that only a proportion of the total number of the boilers in the works should be fitted with mechanical appliances, and propose that the boilers in the new boiler-house only should be so fitted at present. They think it is essential in connection with mechanical stoking, and in view of the large increase in the consumption of small bituminous coal necessitated by the adoption of this proposal, that bunkers should be provided to keep separate the two classes of coal in use, as well as to increase the coal storage accommodation. They suggest that overhead bunkers, having a capacity of 500 tons, be erected in the new boiler-house, and that conveying machinery be employed for the purpose of the more efficient handling of the coal in question. The electrical engineer's estimate for the work is as follows: six mechanical stokers, at £300 each, £1 800; excavations, foundations, etc., for above, £400; one overhead steel bunker capable of holding 500 tons of small coal, £1 000; coal elevator and conveyor, £500; motors and accessories, £300; labour in connection with erection, £500—total, £4 500. With regard to an account for income tax on electricity profits, amounting to £629. 3s., a statement has been prepared by the borough treasurer showing that the taxable income from all sources amounts to £12 583. The committee will report to-night as follows: "Income tax at 1s. in the £ on this sum amounts to £629 3s. There is, however, a substantial set-off against this charge in the amount of income tax deducted by the Council from interest on loans raised for the electricity undertaking. In a recent decision of the House of Lords in the case of the Attorney-General *v.* The London County Council, it was held that where the interest on the loans is paid out of profits the person who makes the payments and deducts the income tax is not accountable to the Crown for the duty deducted. The figures for the current year are not available, but we may mention that last year the amount of income tax deducted from interest on loans was £393. 16s. 3d. We are satisfied that the amount of £629. 3s. is properly payable, and we have accordingly included it in our list of proposed payments."

**Brighton.**—The Town Council have received a report from Mr. Arthur Wright, manager of the Brighton Corporation electricity undertaking, in which he stated that there was not the slightest chance of the general body of ratepayers having to contribute towards the Southwick station scheme, as it could always be made to be as self-supporting as the Brighton electricity undertaking had invariably been in the past; also the cost of carrying out the scheme would be very much less than was estimated in 1900. The Southwick scheme was not only the best solution of the problem of how to furnish the additional supply required for Brighton, but its advantages over the only other alternative—viz., of putting up a new power station in Brighton—could now be shown to be even greater than were foreshadowed in 1899. The sum of £144,628 had on Jan. 31, 1905, been expended in connection with the Southwick scheme (including North-road sub-station). The probable further expenditure that would be incurred in completing the work of providing the additional electric generating and converting plant contemplated in his estimates of March, 1900, would be about £168,522. The great economy obtainable when the new power station was at work would in all probability make it very advisable to order in the year 1906 one additional turbine generating set with the necessary boilers, and the converting machinery for North-road. He estimated that the plant now being erected at Southwick would supply six millions of the units sold per annum in Brighton. The sale of electricity during the present financial year for lighting and tramways in Brighton would be nearly eight million units, and the demand would probably exceed ten million units in five years' time. He considered that the Corporation's electricity undertaking had had the unusual merit of being from its first year of working entirely self-supporting, the general body of ratepayers never having had to contribute towards its maintenance. Judging from recent experience, the undertaking would realise, if sold, more than twice as much money as it had cost to build up. The continued increase of business had been remarkable considering the size of the town, there being now no less than 60 units of electricity consumed per inhabitant per annum, a figure which was not nearly approached by any other town in England. The accumulated profits now allocated for reserve fund purposes amounted to over £15,000 and if the Council followed his advice this year, the reserve fund would probably reach £18 000. The average prices at which electricity was supplied in Brighton to private consumers, street lamps, and to the tramway department—namely, 3·1d., 1·6d., and 1 5d. respectively—were lower than in any other electricity undertaking similarly handicapped as regarded the high cost of coal. Fourteen thousand pounds had been paid out of the net profits in past years towards the relief of the general rates. Over £100,000 would have been, by the end of this financial year, set aside out of the gross profits for the repayment of capital. Only two interruptions of the general supply had occurred during the whole 14 years that the undertaking had existed. The plant at North-road and all the mains in Brighton had been continuously kept in thorough working order and proper repair out of profits, and the cost of all useless and obsolete plant had been written off. The Lighting Committee have resolved that Mr. Wright be engaged as consulting electrical engineer to the Corporation, for six years from April 19 next, to superintend all present and future capital expenditure in connection with the electrical undertaking, at a salary of £600 per annum, and that he be paid a further sum in any year of the said

Digitized by Google

period in which a profit exceeding £5,000, after payment of all debt charges, interest, and working expenses is made, equal to 5 per cent. on the amount of such profit. The committee have been in negotiation for the purchase of premises adjoining the electricity works, and, subject to the approval of the Council, have arranged to purchase the freehold of the premises at the price of £1,800. The cost of erecting the necessary buildings on the site is estimated at £3 200. The committee recommend that application be made for sanction to a loan of £5,009.

## PROVISIONAL PATENTS, 1905.

MARCH 27.

6400. **Improvements in hangers or ears for overhead electric wires.** Joseph Fitzalan Simpson, 6, Bank-street, Manchester.

6419. **Novel method and means for automatically reversing the direction of a trolley current collector upon an overhead conductor for electric traction systems.** Benjamin Smith, 17, Haymarket, Sheffield.

6453. **New or improved method and means for measuring electricity with or without recording or registering apparatus or/and prepayment mechanism.** Charles Orme Bastian and George Calvert, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

6455. **An improved means for fastening together the ears or clips of overhead electric trolley wires and wires used in conjunction therewith.** Arthur Rogers, 88, Chancery-lane, London.

6456. **Improvements in or connected with incandescent electric lamps.** Leo Sunderland and Gilbert Cecil Pillinger, Norfolk House, Norfolk-street, London.

6468. **Process and apparatus for the electrical production of cast iron, more particularly with a view to the manufacture of steel.** Société Electro-Metallurgique Française, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents Act, 1901, March 25, 1904, being date of application in France.) (Complete specification.)

6469. **Electromagnetic speed gear for automobile vehicles and boats.** Société en Participation des Automobiles "La Magnetique," Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents Act, 1901, Oct. 24, 1904, being date of application in France.) (Complete specification.)

MARCH 28.

6523. **Improvements in trolley poles for overhead electric traction.** William Williamson and John Collinson, 6, Bank-street, Manchester.

6535. **An electric wire connecter.** Archibald John Ware, 3, South-road, Handsworth, Birmingham.

6542. **Improvements in electric light fittings, applicable also to gas, oil, and candle light fittings.** Hugo Hirst and Frederick Thomas Cash, 71, Queen Victoria-street, London.

6551. **Improvements in the manufacture of troughs and conduits for the distribution of electricity, water, steam, and the like.** William Hall Keys and George Henry Shakespeare, Prudential-buildings, Corporation-street, Birmingham.

6552. **Improvements in systems of electrical distribution by means of vapour rectifying apparatus.** Peter Cooper Hewitt, The Westinghouse Patent Bureau, Westinghouse-building, Norfolk-street, Strand, London. (Date applied for under Patents Act, 1901, April 8, 1904, being date of application in United States.) (Complete specification.)

6557. **Improvements in apparatus for electric telegraphs.** Siemens Bros. and Co., Limited, and George Sylvester Grimston, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

6567. **Improvements in electric controllers.** Henry Clay Little, 7, Southampton-buildings, Chancery-lane, London. (Complete specification.)

6593. **Improvements in or relating to starting apparatus for electric motors.** Alphonse Constant Reyrolle and Johannes Schuil, 46, Lincoln's-inn-fields, London.

6594. **Improvements in insulation for electric heating devices.** The British Thomson-Houston Company, Limited, 83 Cannon-street, London (General Electric Company, United States)

6595. **Improvements in and relating to dynamo-electric machines.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (General Electric Company, United States.)

6597. **Improvements in devices for detecting leakage in electric transmission systems.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (General Electric Company, United States.)

MARCH 29.

6640. **Improvements in and relating to electricity meters.** Carl Wilhelm, John Busch, and Hugo Roosen, 65, Chancery-lane, London. (Complete specification.)

6650. **Improvements in or relating to galvanic cells.** Walter Schenk, 111, Hatton-garden, London. (Complete specification.)

6679. **Improvements connected with electric railways.** James Dain Lawson and Thomas Littlefair, 70, Chancery-lane, London.

6681. **Improvements in and relating to electric lighting systems and in apparatus therefor.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (General Electric Company, United States.)

6690. **Improvements in and relating to means for electrically maintaining and reproducing recurring movements particularly applicable to clock movements and time transmission.** Robert Mann Lowne and the Lowne Electric Clock and Appliances Company, Limited, 22, Southampton-buildings, Chancery-lane, London.

6691. **Electric safety apparatus for cars or trains.** William Pollard Robertson, 23, Southampton-building, Chancery-lane, London. (Date applied for under Patents Act, 1901, May 12, 1904, being date of application in United States.) (Complete specification.)

MARCH 30.

6721. **Collecting gear for alternating-current machines, homopolar machines, and for conducting electric currents for rotating parts of machinery generally.** Wilhelm Svensson Winkler, 37, West Nile-street, Glasgow.

6752. **Improvements in dynamo-electric machines.** Jakob Emil Noeggerath, 83, Cannon-street, London. (Date applied for under Patents Act, 1901, March 30, 1904, being date of application in United States.) (Complete specification.)

6755. **Improvements in or relating to mercury vapour electric lamps.** Charles Andrew Lee, 24, Cleveland-square, Hyde Park, London.

6760. **Improvements in the electrolytic production of copper wire, strip, or the like.** Sherard Osborn Cowper-Coles, 4, South-street, Finsbury, London.

6775. **Improvements in polyphase current electromotors.** Georges Meller, 18, Buckingham-street, Strand, London.

6786. **Improvements in the construction of plates for accumulators or secondary batteries.** Frederick Julius Gerard and Lotkar Fiedler, 22, Southampton-buildings, Chancery-lane, London. (Complete specification.)

MARCH 31.

6802. **Improvements in automatic electric tramway signals.** Harry Storm and Thomas Simpson, 165, Cathedral-road, Cardiff.

6822. **Improvements in electrical switches.** John Henry Tucker, 128, Colmore-row, Birmingham.

6838. **Improvements in or relating to the suspension of overhead conductors for electrically-operated railways and the like.** Budd John Jones, The Westinghouse Patent Bureau, Westinghouse-building, Norfolk-street, Strand, London. (Date applied for under Patents Act, 1901, April 2, 1904, being date of application in United States.) (Complete specification.)

6865. **Improvements in micro-telephones or instruments containing a telephonic receiver and transmitter in one casing.** Isidore Bernard Birnbaum, 322, High Holborn, London. (The Telephon Fabrik Akt.-Ges. vormals J. Berliner, Austria. (Complete specification.)

6867. **Improvements in the method of wiring or connecting electric conductors and in patterices, junction boxes, and the like therefor.** Herbert Bailey, 6, Lord-street, Liverpool.

6872. **Improvements in apparatus for the electrolysis of gases.** Robert Francis Wood-Smith, 4, South-street Finsbury, London.

APRIL 1.

6882. **A portable gear-coupled water-motor and dynamo, for recharging motorcar electric ignition accumulators and the like.** Frederick John Matson, 11, Gladstone-street, Leeds-road, Bradford, Yorks.

6891. **Improvements in contact breakers for use in connection with electrically-fired internal-combustion engines.** The Electric Ignition Company, Limited, and Frederick Harold Hall, 24, Temple-row, Birmingham.

6904. **An improved method or arrangement for preventing accident or loss of life through the breakage of overhead electric tramcar wires.** George William Fowler and George Hildreth, 6, Finkle-street, Stockton-on-Tees.

6922. **A device for preventing the telephone handle being turned more than once.** Eduard Doye, 17, Mythenstrasse, Zürich, Switzerland.

6946. **Electric fire-alarms.** Fred Francombe, 4, Hill-street, Johnstreet, Kingswood, Bristol.

## COMPLETE SPECIFICATIONS ACCEPTED.

*To be published April 20.*

1904.

7610. **Electric arc lamps.** Foster, Grote, and Ely.

7614. **Apparatus for generating and applying electricity on railway and other vehicles.** Beaumont and Still.

7807. **Machines for transforming or converting electric currents.** La Cour and Rich.

Digitized by Google

**7814. Electric roasting and heating apparatus.** Bauer. (Dutertre and Nodet.)

**7937. Electric meters.** Krausse.

**8316. Electric machine tools.** Fairfax.

**8737. Mechanically-replaced annunciator movements for telephone switchboards.** Oppenheimer. (Act.-Ges. Mix und Genest.)

**9658. Machines for making incandescent electric lamps.** British Thomson-Houston Company, Limited. (General Electric Company.)

**9711. Apparatus for starting and controlling electromotors and circuit breakers adapted for use therein.** Dadge and Lord.

**9718. Electric lamps, especially applicable to electric lamps of the character known as "vapour arc lamps" or "luminous vapour" electric lamps.** Bastian.

**10341. Vapour electric rectifiers and like electric apparatus.** Carolan. (General Electric Company.)

**10559. Galvanic batteries.** Siemens Bros. and Co., Limited, and Eichenauer.

**10681. Methods of conducting chemical reactions by means of a mercury vapour arc.** Carolan. (General Electric Company.)

**11056. Ceiling or wall rosettes for electric lighting and heating.** Lundberg and Lundberg.

**11073. Electric switches.** British Thomson-Houston Company, Limited. (Allgemeine Elektricitäts-Ges.)

**11650. Incandescent gas, acetylene, and electric arc lamps.** Winkler.

**11943. Electric miner's safety lamps.** Rees.

**12123. Alternating-current electric motors.** Davies.

**12247. Electrodes and lamps for arc lighting.** Carolan. (General Electric Company.)

**12267. Electrical resistances.** Davy.

**12334. Construction of dynamo-electric machines.** British Thomson-Houston Company, Limited. (Allgemeine Elektricitäts-Ges.)

**12335. Dynamo-electric machines.** British Thomson-Houston Company, Limited. (Allgemeine Elektricitäts-Ges.)

**12336. Alternating-current electric meters.** British Thomson-Houston Company, Limited. (Allgemeine Elektricitäts-Ges.)

**15772. Manufacture of insulated electric conductors and apparatus therefor.** Siemens Bros. and Co., Limited, and Dieselhorst.

**21322. Process for the etching of metal plates by the aid of electrolysis.** Strecker and Strecker.

**21848. Telegraph recorder.** Roussel and King.

**22326b. Electricity transmission systems.** Justice. (Voltage Controller Company.) (Date applied for under Patents Rule 9, Oct. 17, 1904.)

**22839. Method of supporting electric tramway overhead power-transmitting or trolley wires.** Allen.

**23150. Apparatus for the distribution of alternating electric current.** Berry. (Date applied for under International Convention, Oct. 29, 1903.)

**26095. Controlling systems for electric motors.** Eastwood. (Date applied for under International Convention, March 21, 1904.)

**26099. Electric motor controlling systems.** Eastwood. (Date applied for under International Convention, June 10, 1904.)

**26220. Troughs or conduits for underground electric mains or cables, and for similar purposes.** Wilkinson.

**26282. Switch installations for telephone exchanges and switches therefor.** Siemens Bros. and Co., Limited. (Siemens und Halske, Act.-Ges.)

**27901. Storage cells.** Gardiner.

**27905. Grid or element for secondary batteries.** Gardiner.

**28018. Safety discharge apparatus for excessive voltages in electric circuits.** Siemens Bros. and Co., Limited. (Siemens-Schuckertwerke G. m. b. H.)

**28471. Combined starting and braking device for electric motors.** Hultqvist.

1905.

**3554. Detonator fuses for electric blasting.** Render.

## NOTES.

**Australian Patents.**—Messrs. W. P. Thompson and Co., patent agents, Liverpool, communicate a decision respecting Australian patents which will doubtless be of great interest to holders of such grants. It appears that the decision of the Comptroller not to convert State patents into Commonwealth patents has been reversed. The effect of this is that any State patent can be at once so changed without incurring the fees of each of the various States.

**The Institution.**—The subject for discussion at last week's meeting was "Systems of Electric Units," which was dealt with at the St. Louis International Congress. Mr. W. H. Duddell, hon. secretary to the English delegation, opened the proceedings, and the subsequent speakers included Mr. R. K. Gray, Lord Rayleigh, and Mr. A. P. Trotter, but the hour for adjournment arrived without the discussion being concluded. A summary of the complete discussion will appear in our next issue.

**Side-Slip.**—The committee of the Cyclists' Touring Club announce that nearly 60 devices have been entered for competition for the large monetary prizes offered for a satisfactory solution of the side-slipping problem, while at least an equal number of inventors have put forward their theories without actually entering. The trials themselves will probably take place in the neighbourhood of London during Whit-week upon natural and artificial surfaces calculated to test the merits of the devices to the utmost.

**Royal Institution.**—The following are the lecture arrangements at the Royal Institution after Easter: Prof. L. C. Miall, Fullerian professor of physiology, R.I., three lectures on "The Study of Extinct Animals"; the Rev. H. G. Woods (master of the Temple), three lectures on "Velazquez"; Prof. Sir James Dewar, Fullerian professor of chemistry, R.I., three lectures on "Flame"; Prof. J. A. Fleming, three lectures on "Electromagnetic Waves" (the Tyndall lectures); Prof. H. Marshall Ward, two lectures on "Moulds" and "Mouldiness"; Dr. J. G. Frazer, two lectures on "The Evolution of the Kingship in Early Society"; and Mr. A. H. Savage Landor, two lectures on "Exploration in the Philippines." The Friday evening meetings will be resumed on May 5, when a discourse will be delivered by Prof. H. E. Armstrong on "Problems Underlying Nutrition." Succeeding discourses will probably be given by Prof. E. Fox Nicholls, Sir Charles Eliot, K.C.M.G., Prof. J. W. Brühl, Mr. George Henschel, and Sir William H. White.

**Electrolysis with Alternating Current.** — An abstract of an article on this subject by Mr. Carlo Rossi appears in the *Journal* of the Chemical Society. Solutions of potassium chlorate acidified with sulphuric acid exhibit complicated phenomena when subjected to the action of an alternating current between copper or iron electrodes. The copper electrodes become coated with cuprous chloride, copper dissolves, and a bluish-green basic chlorate, $Cu(ClO_3)_2,3Cu(OH)_2$, separates from the solution. When a direct current is used, cuprous chloride is formed at the anode, together with smaller quantities of basic chlorate and chloride; the solution, from which a complex mixture of cupric hydroxide, cupric oxide, copper, and cupric chloride separates out, does not contain dissolved copper. It is supposed that the copper passes into solution at the anode as cuprous ion, which reduces the chlorate, cupric copper being then precipitated by the alkali formed at the cathode. The non-reversibility of the change at the electrodes when alternating currents are used is probably due to the rapid removal of the cuprous ions in this manner. When, on the other hand, the potassium chlorate is replaced by sodium chloride, the alternating current dissolves very little copper. With iron electrodes similar phenomena were observed.

**Motor Omnibuses.**—Tramway undertakers, in promoting their schemes, have had to contend with a large amount of opposition through the jealousy of railway companies. Now that the latter are competing for the street traffic by running motor 'buses, tramway owners consider it is their turn to go in for protection, and to this end conferences have been held in which both municipal and private undertakers have participated. At the adjourned meeting held at the Westminster Palace Hotel on Saturday, it was reported that the Midland and the Great Western Companies had withdrawn their omnibus clauses, and that the North-Eastern Railway Company were prepared to make some concessions in order to meet the views of municipal and other tramway owners. Sir Edward Grey, M.P., as a director of the North-Eastern Company, intimated that, whilst they would try to meet the objections of tramway owners in urban districts, they desired full liberty for giving motor omnibus facilities in country districts. The meeting was adjourned to consider what amendments the North-Eastern Company are willing to make in their motor omnibus clause.

**Electricity in Workshops.**—At Newcastle last Friday, under the presidency of Mr. Gerald Stoney, a lecture upon "The Electric Equipment of Workshops and Shipyards" was delivered to the local students of the Institution of Civil Engineers by Mr. Wilfrid Hill. After alluding to the great industrial development of electricity in recent years, the lecturer remarked that this form of power might greatly tend to modify economic conditions in the near future. Electrical engineers had rendered no small service to manufacturers by calling attention to the actual cost of power. Mr. Hill then discussed the comparative cost and advantages of steam, gas, and electricity as forms of motive power, and showed that in general electricity was the most economical in actual cost, as also in the amount of space required. Having briefly referred to the considerations which govern the choice of system when laying out an electric installation, and also to the question of public *v.* private supply, the lecturer gave a description of various types of motors, making special reference to induction motors, on account of their suitability for shipyards and places here they might be subject to rough usage.

**Hygienic Telephony.**—A little while back the telephone authorities at Paris introduced a simple arrangement for disinfecting telephone transmitters, and now our General Post Office has followed suit. The contrivance consists of a cap containing an antiseptic pad, hinged to a piece that attaches the whole in a simple manner to the transmitter, and included with the outfit is a bottle of a pleasantly perfumed but powerful disinfectant, a few drops of which poured on the pad every three or four weeks keeps the interior of the mouthpiece pure. When the conversation is finished, the cap is simply snapped by the user over the mouthpiece, rendering it germ-proof. The General Post Office supplies this outfit, which is designated "telephonine," at 5s. Another item of telephonic news is that in September next direct communication between Vienna and Trent (Italy) is expected to be an accomplished fact, and this will probably lead to direct communication between Rome and Berlin. Another matter upon which the Postmaster-General was questioned in the House referred to the telephonic rates between London and Paris, which, Lord Stanley implied, were as reasonable as the conditions would allow, and, consequently, he did not propose to take any steps for their reduction.

**Street Railways in the States.**—The American Census Office on Street and Electric Railways has just issued

Digitized by Google

a voluminous report, which contains a quantity of information upon all phases of this subject; but it serves to illustrate none more conspicuously than the effect of such services in transferring the population from the centre of large cities to the suburbs for residential and, in some cases, industrial purposes. The Manhattan borough of New York, which is some seven miles from the city, practically doubled its population during the decade 1890-1900, and the great majority of its wage-earners made daily use of the street railways. Other suburbs also show substantial increases in this respect. The same process has been going on in Boston, for while the centre of the city is rapidly becoming depopulated from the residential point of view, the outlying areas show enormous expansion. Philadelphia, again, presents a similar aspect. The cities named exemplify the influence in the most marked degree, but there are many others where it is scarcely less pronounced. In Philadelphia especially the transport facilities have led to the utilisation of the outlying areas for manufacturing operations, the various industries assembling themselves in specialised centres. Electric traction greatly predominates, and electricity is the chief illuminant on the cars. The almost universal fare for the urban lines is 2½d., reductions being made for books of tickets.

**Central Technical College.**—We have received a copy of "The Central," dated March, which contains an illustrated article on "Victoria Falls Bridge: Design and Construction of Steelwork," by Ralph Freeman; a continuation of the article entitled "The Mechanism of Combustion," by H. E. Armstrong; a short description of London University; an illustrated article on "The Klingenberg Carriage Switchgear," by J. Griffin; and "Old Student Notes." Mr. Griffin considers the type of switchboard most suited to high-pressure stations, and lays down 11 conditions which should be satisfied. These, he thinks, are best met by the switchgear lately developed by Dr. Klingenberg, the distinguishing feature of whose system is the assemblage of all the apparatus belonging to any generator, feeder, or distributor upon an iron framework fixed upon a number of wheels, which enable the so formed carriage to be moved along a pair of rails. Upon the back of this carriage are fixed a number of carefully insulated plugs or blades, which fit into a corresponding number of similarly insulated contacts forming the terminals of a generator, feeder, or distributor on the one hand, and the ends of connections to the 'bus bars on the other. By this simple arrangement it is possible, by pushing the plugs or blades on the back of the carriage into the contacts behind the same, to connect the generator, feeder, or distributor, through an oil switch, with the 'bus bars. A simple locking device renders it impossible either to push the carriage on to or to withdraw it from the contacts with the oil switch closed.

**Societe Belge d'Electriciens.**—In the April *Bulletin* of this society there appears the conclusion of an excellent article by Mr. J. Carlier on the apparatus for measuring time, speeds, and acceleration of railways. The author is an engineer of the State railways of Belgium, and is able to give a number of illustrations from actual experience on the same. The first part of this article deals with apparatus for measuring cyclic variations in speed such as are interesting to the designer of alternators which have to work in parallel. The last portion of the article deals with the automatic recording of acceleration. Amongst the instrument described for this object is the Desdouits dynamometer, which depends for its action upon the inertia of a pendulum. By means of this any changes in speed are exactly recorded on the cylinder. Again, if the driving force is discontinued the apparatus measures the negative acceleration of the train due to the running friction. In connection with this apparatus a second pencil is provided to record the actual revolutions of the wheel, so that there is a means of determining the exact points on the railway represented by the points on the acceleration curve. An actual diagram is reproduced which was taken with this apparatus on the line from Paris to Niort. This clearly shows that the negative acceleration in braking is between two and three times that which could be obtained by the locomotive used to accelerate the train. An instrument designed by Mr. Carlier himself is also illustrated and described, and this, again, depends for its action on the inertia of a pendulum. Acceleration meters which depend on the movement of a liquid are also briefly referred to. One such instrument designed by Mr. Gisbert Kapp is particularly mentioned. The article is one which will repay careful study by tramway and railway engineers who are investigating the actual performance of their rolling-stock.

**The Trans-Siberian Railway.**—The Electrotechnical Association of St. Petersburg recently considered the proposed electrification of the Trans-Siberian Railway, to which we briefly referred a few months back. Apart from the abnormal conditions due to the Far East campaign, the traffic, both passenger and goods, is stated to have expanded to such an extent that the present service is inadequate. Two important obstacles in the way of speed acceleration are lightness of the rails and insufficiency of water, though the latter difficulty might perhaps be met by "canalisation." The relaying of the track, however, would entail a heavy expenditure of time and money, and this has led to the suggestion that the system should be electrified. Prominent among the advocates of this plan is Count A. F. Lubienski, who holds that the conversion is imperative. The existing track would be utilised, and electric trains on the multiple-unit system would not be handicapped by the numerous curves and gradients to the same extent as are the steam locomotives. The rivers and waterfalls along the route would probably be utilised for generating energy, the power stations being located at intervals of 60 to 120 miles, whence the current would be distributed at a pressure of 100,000 volts to sub-stations in both directions. The scheme seems well worthy of consideration, though the Russian Government is not likely to have much money to spend in this direction just yet. When peace has been declared, perhaps another railway loan could be raised in France, which already has large financial interests in the undertaking. Another project that was discussed on the same occasion refers to the electrification of the Caucasian railways, for which the district is well adapted on account of its abundance of waterfalls. This proposal also seems to merit further attention, but here, too, financial considerations are likely to be an obstacle to early action.

**Telephone Transfer.**—The employés of the National Telephone Company have shown great activity in regard to their status on the undertaking being transferred to the Government. In the House of Commons the other day, the Postmaster-General, in reply to a question, stated that he had received two memorials requesting him to receive a deputation, which he hoped to be able to do shortly. In the meantime, he might say that it would probably be found necessary to transfer to the Post Office service all efficient members of the executive staff previously required by the company. Those persons who were appointed to the established staff of the Post Office would at once benefit by the conditions as to pensions which applied to their staff, but he could hold out no hope that operators and other classes, who were not entitled to any pension under their present employment in the company's service, could be allowed to have the period of that service taken

Digitized by Google

into account in reckoning their Post Office service. In the case of those members of the staff who contributed to the present pension fund it was expressly stipulated in the agreement that any obligation arising out of their service previous to their transfer fell to be met by the company, and he had no reason to suppose that the company would not meet that very fully. It would be open to the Select Committee to consider the agreement and hear representations from the company's staff. The Postal Telegraph Clerks' Conference has likewise been active. Apparently the concessions promised by Lord Stanley are far from satisfying the employés, who want the recommendations of the Bradford Committee adopted in their entirety. It will be remembered that Lord Stanley stated not long ago that this was impossible, the committee having exceeded its function. Amongst other things it was decided at the conference to again recommend the introduction of the threepenny telegrams, on the ground that this would give a stimulus to telegraphy, and so improve the operators' prospects.

**Bell Telephone Company.**—The annual report of the American Telephone and Telegraph Company shows that the remarkable growth of the Bell system continues unabated. The increase during 1904 of instruments in the hands of Bell licensees was 701,047, or more than the total number at the beginning of 1896, while the increase of stations was 274,466, the total number eight years ago being 281,695. The aggregate of stations at the beginning of the present year was nearly 1,800,000, and the total mileage of line just short of 3,500,000 miles. Approximately the receipts for the year were £4,000,000, the dividends paid amounting to £2,000,000, while £120,000 was placed to reserve and £180,000 carried forward. The revenue showed an increase of more than £400,000 over the previous year, the expenditure rising from £1,200,000 to £1,480,000. In connection with the agitation that has been going on respecting the costliness of the public services, we note that the New York Telephone Company (a Bell concern) has decided to reduce its tariff from May 1 as follows:

| No. of messages. | Old schedule. | New schedule. |
|---|---|---|
| 600 | £15 | £12 |
| 1,200 | 22 | 18 |
| 1,800 | 28 | 22 |
| 2,400 | 33 | 27 |
| 3,000 | 37 | 32 |
| 3,600 | 40 | 36 |
| 4,500 | 46 | 40 |

This company has pursued an open policy respecting its finances, having given an independent committee unrestricted access to its books, which is expected to go a long way in allaying hostility to companies which own public concessions. The drawback to this publicity is that the unthinking section of the community will not always interpret the accounts aright. Respecting return on capital, for example, due allowance would probably not be made for plant which had been "scrapped" in order to keep march with scientific progress. The New York Telephone Company has thrice completely reconstructed its exchanges.

**A Freight Subway.**—Some half-dozen years ago the Illinois Telegraph and Telephone Company started the construction of a series of tunnels under the streets of Chicago for the cables of the company's telephone system. This network of tunnels is now utilised for a subterranean goods transport system, of which a description is given in the *Scientific American* The tunnels are about 20ft. below the street level, and consist of trunk and branch lines. The track is of 2ft. gauge, laid with 56lb. T rails. Part of the line is on the overhead trolley principle, the remainder being on the Morgan third-rail system. This latter consists of a perforated metal plate (½in. thick and 4in. wide), forming a rack, which is bolted between two lines of timber stringers, which serve to protect and support the rail. The locomotives are of the class used in mine haulage work, but are peculiar in the method of taking current. The rack rail serves both for traction and as a power conductor, the current being led to the motors, which are geared to the axles with suitable controlling devices. The track rails are used for the return current. One important advantage of this system is to relieve the streets of the city from a great quantity of traffic. Thousands of tons of coal, ashes, and refuse from the excavation of houses in course of building are thus conveyed. Besides this, the system is daily used for hauling large consignments of mixed freights formerly transported over the streets, and the company, which is named the Illinois Tunnel Company, recently entered into a contract with the Government under which a large proportion of the mails will be carried from the railway stations to the Post Office by the same means. A further plan to utilise the tunnels for mail purposes involves the building of chutes connecting the post boxes with the tunnel, so that the mails can be collected by the cars. It is estimated that altogether more than 112,000 tons of mixed freights are moved to and from the numerous Chicago railway stations daily, which caused great congestion in the streets, and this the subways have relieved. The cars of the tunnel company are run directly into the railway freight houses, loaded, and run through the tunnels to the consignees. Here the cars are run into the basement of the warehouse through an opening cut in the masonry, raised to the desired floor on elevators, and unloaded. If the goods are not intended for immediate delivery, the cars are run into the company's storehouses and kept there till required. Every building on the route of the tunnel can be connected to it by a lateral shaft.

**Junior Institution of Engineers.**—A large number of members of this institution visited the Willesden power-house of the North Metropolitan Electric Power Supply Company at Taylor's-lane last week, when they were conducted round by the station superintendent (Mr. F. D. Napier) and his assistants, in the unavoidable absence of the engineer, Mr. E. T. Ruthven Murray. The continuous current is generated directly at a pressure of from 490 to 540 volts suitable for the 2 by 240-volt network surrounding the works, and this fixes the average pressure of the alternating-current terminals of the same generator at 316 volts, the machines being, as it were, rotary converters driven by engines. Step-up transformers with a ratio of 1 : 9 are employed, raising the pressure to an average of about 2,850 volts, at which it is transmitted to the sub-station. There variable-rate step-down transformers and rotary converters once more reduce the pressure down to that suitable for a 240-volt three-wire continuous-current distribution. The site of the station occupies an area of 3½ acres, and adjoins the Midland and South-Western Junction Railway, by which access can be gained to all the great northern lines. The boilers are of the Babcock-Wilcox type, arranged in pairs, built in glazed brick settings. Draught gauges are fitted, and an "Ados" registering $CO_2$ recorder. There are Hall steam feed pumps, and a Mather and Platt electrically-driven pump, the latter having a special device for effecting its regulation. The arrangement of steam mains is novel. A jet condenser by Ashton, Frost, and Co. is provided for the two 300-kw. sets, while the other sets have their own surface condensers. There is a cooling plant, supplied by Korting Bros., on which are four lines of spraying jets. The surface of the pond is 30ft. by 200ft., and it is capable of dealing with 100,000 gallons of water per hour, which is

Digitized by Google

the storage capacity of the pond. All water is softened by a Brunn-Lowener apparatus, in which milk of lime and soda is used. For the general arrangement, and for the design of many of the special details of the low-tension continuous-current switchboard, Mr. Ruthven Murray was responsible. His object was to arrange a switchboard embodying the distinctive and valuable features of the Ferranti high-pressure cellular type of switchgear for low-pressure working. The principal feature of novelty in the low-tension switchboard is that four separate 'bus bars are provided, and there are "selector switches," which enable any machine or feeder to be connected to any 'bus bar. The battery-room contains 250 Tudor cells, with a capacity of 840 ampere-hours at a 10-hour discharge rate.

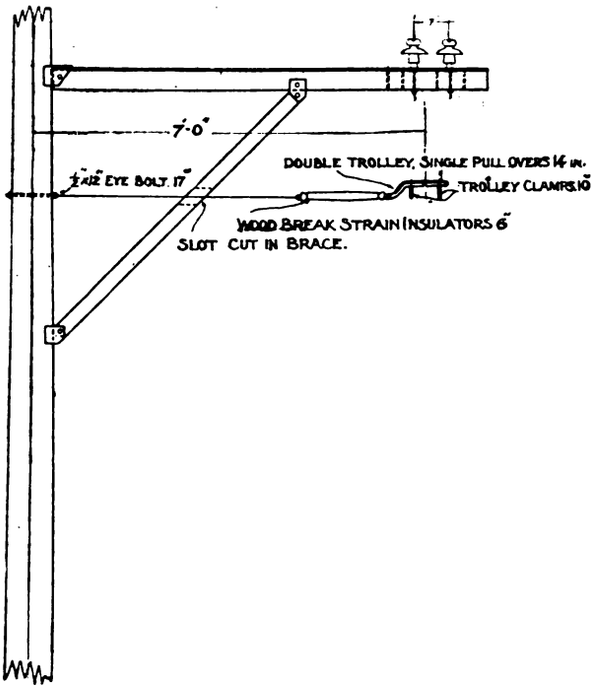
**Alloys of Copper and Bismuth.**—At the meeting of the Faraday Society last week Mr. A. H. Hiorns gave an illustrated lecture on this subject. The results of previous researches on copper alloys appeared in the society's *Transactions* for April of last year. The author alluded to the investigations into the effect of bismuth, from 0·1 to 0·5 per cent., on copper made by Prof. Arnold, who found that the investing membranes surrounding the grains of copper appeared to be split down the centre, presenting a definite plane of cleavage. Dr. Gautier obtained a freezing-point curve similar to the author's, but his temperatures are generally higher. The microscopic evidence mainly confirms the records of the freezing-point curves, of which there are four branches—pure copper and pure bismuth at the extremes and solid solutions of copper in bismuth or bismuth in copper at intermediate points. The types of pattern on the etched surfaces depend on the position of the freezing points on the curve. The eutectic points occur at 243deg. C. and 1,020deg. C., with a transition point at 858deg. C. From this point with increase of bismuth in alloys containing 30 to 43 per cent. of copper, the curve is practically a horizontal line showing little differences in the freezing points. In this region two possible chemical compounds may be present—viz., $Cu_3Bi_2$ and $Cu_2Bi$—but there are no well-marked indications of such, either in the freezing-point curve or in the micro-sections. Such compounds can, therefore, only exist in contact with solutions containing excess of bismuth. The above-mentioned transition point is the transition point between solutions of copper in bismuth and bismuth in copper, and at this point the two solutions have probably the same freezing points, each being lowered by the addition of the other, thus forming a conglomerate of the two mixed crystals, which here exist in equilibrium. Copper with small percentages of bismuth consists of polygonal grains, the boundaries of which contain a thin line of bismuthide. When such copper is broken the line of fracture follows this line. With 2 per cent. bismuth the surface shows a characteristic eutectic structure. With increase of bismuth gradually widening boundaries to the grains appear, and the interior is of a eutectic nature, which also increases with the addition of bismuth. With 57 per cent. bismuth the whole surface is composed of grains of the two solid solutions, one of a light-grey and the other of a light-red colour. With 60 to 67 per cent. bismuth the alloys are composed of the two solid solutions mentioned above, with the addition of dark-blue grains, probably the compound $Cu_2Bi$. With 70 to 90 per cent. of bismuth there are two main constituents, consisting of the red solid solution in a eutectic mixture. With 97·2 per cent. of bismuth the whole is decidedly a eutectic mixture. The structure of alloys containing 98 per cent. bismuth and upwards resembles pure bismuth. The chairman, Prof. A. K. Huntington, remarked that previous observers had not noted the eutectic point of pure copper and copper-bismuth solution at 1,020deg. C., shown at D on the author's cooling curve. He hoped Mr. Hiorns would make his study more complete by systematically examining chilled alloys as Heycock and Neville had done in the case of the copper-tin series. Mr. Hiorns, in reply, said that repeated experiments justified his belief in the existence of the eutectic at 1,020deg. C.

**Lightning Conductors.**—On Saturday last, Mr. W. H. Whitehouse, M.I.E.E., read a paper before the members of the Birmingham and District Electric Club on "Lightning Conductors." Quoting from Fuller's "Church History," that "scarcely a great abbey or cathedral in England exists which once at least was not burned with lightning from Heaven," and Sir W. Snow Harriss's evidence as to the annual damage done to the British Navy, he referred to Sir W. Preece's statement before the Institution of Electrical Engineers in 1889, that in 1872 19 per cent. of the telegraph instruments were damaged by lightning. Against this the number damaged in the year 1889 was only 1·3 per cent, this result being due to the employment of an ordinary galvanised No. 4 iron wire down each pole. During the year 1899 the following casualties were mentioned in the British Press: people killed, 25; injured, 114; churches and chapels struck, 17; hotels, 12; castles and country mansions, 5; houses, cottages, and buildings, 237; while in America during the same year there were 562 killed and over 800 injured. The lecturer then proceeded to describe the phenomenon of the lightning discharge—forked, sheet, and globular, St. Elmos fire, thunder, etc. He alluded to the work of Franklin at Philadelphia and M. Dalibard at Marby-la-Villa in proving the identity of lightning with ordinary frictional or static electricity as shown by the action of the Leyden jar, electroscopes, etc. [Apparently the lecturer did not introduce any mention of that neglected scientist, Prohop Dilwisch (which the erudite have Latinised into Procopius Divisa) who preceded Franklin in the construction of the lightning conductor] He referred to the difference of opinion as to the relative merits of points or knobs on the top of a conductor, which gave rise to such heated discussion in the reign of George III. During the past 20 years, owing to increased knowledge of electrical science, the theory of lightning has been entirely changed, it having been discovered that the discharge is a high-frequency alternating current, and not a direct one, as formerly supposed. As the laws of ohmic resistance do not apply, neither does the superiority of copper over iron as a conductor. Attention was directed to the papers read by Sir Oliver Lodge before the Society of Arts, the British Association, and the Institution of Electrical Engineers in 1888-9, when Sir Oliver showed some interesting experiments with syntonic Leyden jars connected to alternative paths, and giving impulsive rush discharges. The experiments bearing on the new theory were fully explained and illustrated on the screen, and the lecturer, in concluding, gave a summary of what may be deemed (in our present knowledge of the subject) the essentials of a proper system of lightning conductors. Through the kindness of Mr. A. Hands (Messrs. G. W. Grey and Sons, Leadenhall-street, E.C.), the paper was illustrated by a number of photo slides of churches and buildings damaged by lightning.

**Single-Phase Railway.**—A description appears in the *Western Electrician* of the Bloomington, Pontiac, and Joliet Electric Railway, which is equipped with the single-phase tracks and system of the General Electric Company. It is intended to operate the line at 3,000 volts without any feeders by simply connecting the power station at one end to two No. 00 trolley wires with which the line is equipped. The trolley wires are hung from three 8in.

Digitized by Google

steel stranded catenary conductors, from which they will be supported every 10ft., though at present the supports are placed only every 100ft. midway between the poles, which are 7ft. from the centre of the track, and are fitted with a wooden instead of an iron bracket. The trolley wires are supported 9ft. 6in. from the track, and the catenaries are insulated by Thomas insulators placed 10in. apart, these insulators being secured on malleable iron pins with Portland cement. The trolley wire is supported by mechanical clips having bronze hooks, which latter slip over the catenary cable and are then hammered down so as to prevent them from coming loose. We reproduce an illustration of the overhead equipment. Within the limits of Pontiac a side pole instead of bracket construction is used. Both the trolley wires and catenary cables are supported from span wires, the catenary spans, which are just above the trolley spans, being used for safety. Both the trolley and catenary strain insulators are of impregnated wood 24in. long, similar to those on the Schenectady-Ballston line, on which the first General Electric single-phase equipment was made. Additional insulation is secured by porcelain insulators located at the



pole to which the span wire is attached. The ordinary form of trolley pole and wheel is used, exceptional precautions being taken, however, to insulate the trolley base. The cars are equipped with four 75-h.p. General Electric 25-cycle, series compensated motors. Unlike the cars on the Schenectady-Ballston line, which operate on both direct and alternating current, the cars are equipped for alternating supply alone and with a method of control which varies the speed by varying the potential by means of a transformer.

**Direct-Current Commutation.** — Patents have recently been issued in the States to Mr. F. M. Young and Mr. G. S. Dunn, and assigned by them to the Crocker-Wheeler Company. The common object of the patents, which are described in the *Electrical World* of New York, is to improve the method of commutation in direct-current machines by increasing the resistance in the path of the current from the live brush into the advancing terminal of the commutating coil without increasing the resistance between the live brush and the trailing terminal of the commutating coil, so as to accelerate the reversal of the current in the coil. For this purpose the inventors use auxiliary "dead" brushes, which are insulated not only from the live brush and its holder, but from every other part of the machine, so that they are completely dead except for their contact with the commutator bars. In the accompanying illustrations D is the live brush, while the dead brushes are represented by E, the insulation surrounding each of the dead brushes being indicated by the letter F. As will be seen in Fig. 2, coil *a* is receiving current from

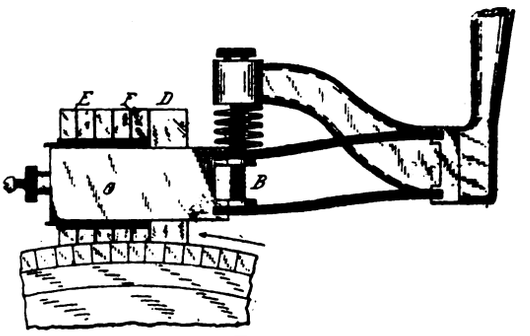


FIG. 1.

its left-hand or leading terminal, which flows out at the trailing terminal and into the coils to the right. When the coil *a* reaches the position of coil 1, it is short-circuited through the live brush, but owing to the inductance current continues to flow in the same direction as before, although of a diminished value. When the coil *a* reaches position 2, it is short-circuited through a dead brush, and current tends to flow from the live brush in at the trailing

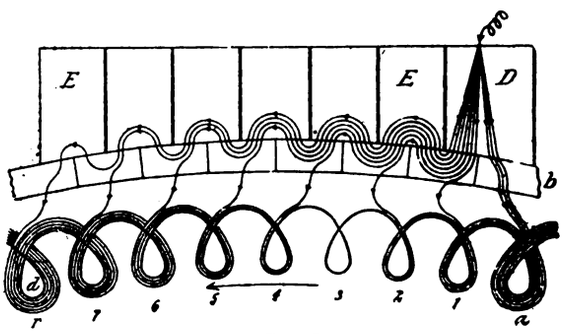

FIG. 2.

terminal; but this, which would effect a reversal of the current in the coil, is opposed by the self-induction of same. Current also tends to flow from the live brush and in at the leading terminal, but this is opposed by the two additional surface contacts between the commutator bar and the first dead brush and this brush and the next commutator bar. It will be seen from Fig. 3 that the planes of separation between the brushes are inclined relatively to the strips of mica on the commutator for the purpose of preventing an instant of absolute rupture of the commutating

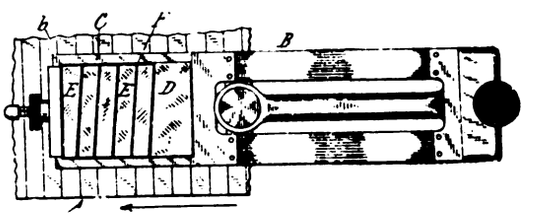

FIG. 3.

current when the trailing side of the live brush leaves the commutator bar, thereby avoiding any sparking at the brushes or burning of the commutator bars. An effect of this arrangement is that a gradually increasing resistance is introduced not only into the advancing terminal of one, but into the advancing terminals of a number of successive coils, in such a way that at each terminal a resistance of different amount from that at any other terminal is produced at a given time, forming as many paths of current as there are different resistances.

## ARMATURE WINDINGS OF THE CLOSED-CIRCUIT TYPE.

BY WM. CRAMP.

*(Continued from page 475.)*

### Two-Circuit "Short-Connection" Rings.

Further consideration of Fig. 14 suggests the possibility of another form of two-circuit ring. We may use the system of end connections in Fig. 14 for connecting in series the spirals of a ring-wound armature.

Fig. 24 illustrates such a case. In it we have simply taken a ring armature and placed upon it 18 groups of spirals, which are then connected according to the scheme used for the drum in Fig. 14. Thus group 1 is connected to group 6, and group 6 to group 11, and so on regularly until the winding closes. If we reduce each of the groups in Fig. 24 to one single inductor, we have exactly the same winding as Fig. 14; consequently this may be described as simply a method of placing several turns per commutator section in series upon a two-circuit drum-wound armature, without the necessity of each turn passing any great distance along

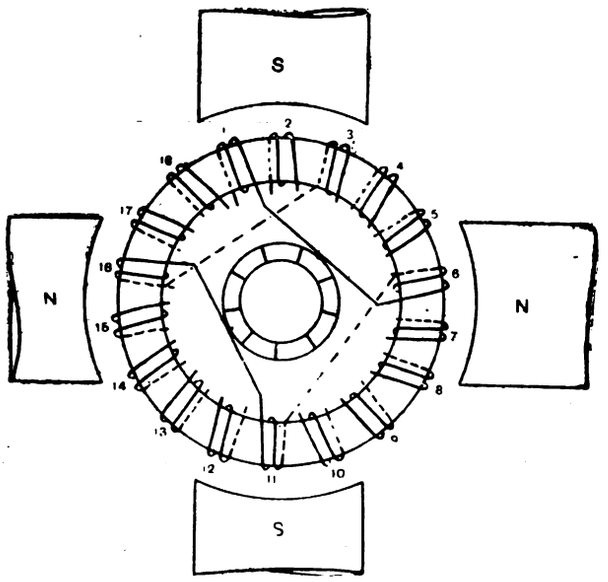

FIG. 24.

the periphery. We carry this out by providing the drum winding with a ring core, and connecting the turns in series through this core. (Of course the same sort of system could be applied to any drum armature.) This has all the disadvantages of a drum winding, except for the fact that with the same number of turns upon the armature the number of end connections will be less, so that less end room is required. All the other characteristics of the drum, such as maximum voltage existing between neighbouring wires, no end connections passing through the armature, etc., are still retained.

The form of ring winding (Fig. 24) is known as the "short-connection" type, for reasons which are obvious when contrasting Figs. 23 and 24. It is not much used, and never for low-voltage, high-current machines; consequently there is no interest in discussing the possibilities of multiple winding, which, of course, are precisely those of the two-circuit drum.

### Formula for Two-Circuit "Short-Connection" Rings.

We have simply to substitute in the formula for two-circuit drums the letter $s$, indicating the number of sets of spirals for $w$, the number of groups of inductors, so that it will read

$$s = p\,y \pm 2\,m.$$

This is the last form of two-circuit winding of any importance, and we will therefore summarise our results.

### Laws of Two-Circuit Windings, Drum or Ring.

Two-circuit armatures are of two classes—drum and ring.

*Drum Armatures.*—These are of necessity "wave" windings, the system of end connections being such that they pass continually in one direction around the armature periphery when the winding is reduced to its simplest form—*i.e.*, with two inductors per commutator section.

These armatures may be simplex, duplex, triplex, etc. (or simple double triple, etc.), according to the number of parallel paths (through the armature) from brush to brush.

A multiplex winding may be singly or multi-re-entrant; this re-entrancy depends upon the relation ship between the number-pitch and the number of windings.

There must be in all cases an even number of inductors which must be a multiple of the number of commutator sections (and also in the case of a slotted armature of the number of slots).

The rules for connection are given by the general formula

$$w = p\,y \pm 2\,m,$$

where $w$ is the number of inductors;
$p$ is the number of poles;
$m$ is the number of windings required;
$y$ is the mean number-pitch.

$y$ must for all simplex windings be either an odd number, or two number-pitches must be used alternately $(y + 1)$ and $(y - 1)$.

For multiplex windings, $y$ should be either an odd number or "$m$" times an odd number, or some multiple of an odd number less than $m$. Attention to this will obviate the use of different pitches at the two ends of the armature.

The re-entrancy is given by the H.C.F. of $m$ and $y$.

The number of sets of brushes absolutely essential is two, one positive and one negative. But there may be more sets in parallel with these according to the number of poles. Each brush must cover a number of segments on the commutator greater than $m - 1$.

Of two-circuit ring windings we may say: They are of the two kinds known as the "long-" and the "short-connection" respectively.

The former consist of $s$ spirals (or sets of spirals connected according to the formula

$$s = p\,y \pm m,$$

and $s$ may be even or odd according to the number of poles of the machine.

The latter consist of $s$ spirals or sets of spirals connected according to the formula

$$s = p\,y \pm 2\,m,$$

and $s$ must be an even number.

In other respects these ring windings follow the same laws as the two-circuit drum windings, as already explained. But as they possess no advantages except for high voltages, the multiple (×) forms of them possess no practical interest.

In calculating the voltage of a two-circuit ring winding, the same principles apply as were pointed

Digitized by Google

out in the comparison of multiple-circuit rings with multiple-circuit drums. A two-circuit ring of 37 spirals would, in a certain field, at a certain speed give the same voltage as a two-circuit drum with 37 inductors, if such a thing were possible; and the connection between the two-circuit and multiple-circuit form of armature lies in the fact that, if the above ring of 37 spirals were connected as a multiple-circuit armature, the voltage would be, in the latter case, $\frac{2}{p}$ of the voltage in the former, while the current would be proportionally increased. (Lines per pole and speed are assumed to be constant.)

We have already compared to some extent the value of multiple and two circuit windings, and to accentuate this we may well here give an example similar to that for multiple-circuit windings given on page 302.

**Example of a Two-Circuit Winding.**

We will assume that the same size of field frame and armature which were used on page 302 are again required to give 2 kw., but this time the maximum electromotive force is to be 470 volts. From the formula we again calculate the number of inductors, and find that it is 2,360. This means that if the winding is multiple-circuit, there will be 1,180 inductors per pair of poles. The wire which will be used for winding in the multiple-circuit case must carry 1·12 amperes, and there will be 40 of these wires per slot with 60 slots.

Such a winding is difficult on account of the small size of the wire, and wasteful on account of the room in the slot taken up by the wire coverings. We turn, then, to the two-circuit formula to see what number of slots it is possible to use.

We find from the formula that

$$w = p.y \pm 2m$$

or

$$118 = 4 \times 29 + 2,$$

which shows that a simple armature may be wound with 59 slots, and number-pitches of 29, and 59 commutator sections. This armature will have two inductors per commutator section, and will give (from the electromotive force formula) 47·2 volts. Obviously, then, if we take 20 inductors per section—*i.e.*, wind ten turns in place of one—we have in each slot two half-coils in place of the two inductors arranged above. The last turn of half-coil No. 1 (in slot 1) will be connected to the commutators, and then to the first turn of half-coil No. 30, which lies in slot No. 15, exactly as described on page 402.

The number of conductors on the armature will be 1,180, and the gauge of wire necessary is No. 21 S.W.G. This is obviously a very much superior arrangement to that of the multiple-circuit winding, and we may therefore decide to adopt it. Consequently we have

| | |
|---|---|
| Inductors | 1,180 |
| Number of commutator sections | 59 |
| Gauge of wire | No. 21 |
| Re-entrancy | Single |
| Symbol | o |

A comparison of these two armatures with that arranged on page 302 will throw light upon the relative advantages of multiple and two circuit windings.

In the first place, had the standard armature of page 302 possessed 59 slots, it might have been used for both multiple and two circuit windings, provided that there were 59 sections in the commutator. This emphasises the very important point that in getting out standard discs *it is the two-circuit windings which should be considered;* since any number of slots whatever can be used for multiple-circuit armatures.

Next, a comparison of the two armatures just arranged shows how with a two-circuit four-pole winding half the number of inductors only are required for a given voltage; and we are enabled to use a wire of stouter gauge. This, again, is an important point, not only from the winder's point of view, but also on account of the room taken up in the slot by the insulation of many small wires.

Finally, we may point out that these differences between multiple and two circuit armatures increase with the number of poles. Thus: if a 10-pole machine with a given number of inductors be arranged as multiple and as two circuit respectively, in the latter case it will give five times the voltage and one-fifth of the current that it did in the former, with the same number of lines per pole and at the same speed.

(*To be continued.*)

## EXETER ELECTRIC TRAMWAYS.

**In our last issue we briefly announced the fact that the first portion of the above tramways were opened by the Mayor of Exeter on Tuesday, the 4th inst. The following details of the system and of the generating station from which these tramways are supplied are of interest. The tramway conversion scheme has been the subject of heated controversy in Exeter since it was first suggested in 1900, but the Corporation has succeeded in its policy of making the tramways a municipal undertaking.**

**The routes already equipped and opened for traffic run from Livery Dole to Eastgate, and thence, *vid* High-street and Queen-street, to St. David's Station, while another line, starting from the Cemetery-road, runs through Blackboy-road and Sidwell-street to join the former at Eastgate. This line will be carried through to Dunsford Gate, St. Thomas, as soon as the removal of existing obstructions has been completed, while an extension to Cross Park, Heavitree, of the first route has already been agreed upon and is rapidly being constructed. The construction work has been carried out to the specifications of the Council's engineers—Mr. J. E. Waller (consulting engineer), Mr. Thomas Moulding (city engineer and surveyor), and Mr. H. D. Munro (city electrical engineer)—acting jointly. The latter two gentlemen supervised the work upon the spot. The contractors for the tramways are Messrs. Dick, Kerr, and Co., of London and Preston. The car-shed has been built to the designs of the city engineer, the contractor being Mr. William Blake, of Plymouth. The generating plant has been installed under the superintendence of the city electrical engineer, the contractors being the British Westinghouse Company, of London and Manchester, and Messrs. Bruce Peebles and Co., of Edinburgh.**

**The routes now nearly equipped are 4¼ street miles in length, and the tracks consist of 2⅜ miles of double line and 2⅜ miles of single line, with passing places. Double line and interlacing line has been constructed in the busiest thoroughfares in order to facilitate the ordinary traffic of the streets. The gauge adopted is 3ft. 6in. The rails are steel of the girder type, 6in. in depth, and weigh 90lb. per lineal yard. The foundation for the rails (Fig. 1) and paving is constructed of cement concrete 6in. thick. In addition to this concrete underbed, the rails are packed up to the true alignment by fine cement concrete, averaging ¾in. in thickness. The points and crossings were supplied by Messrs. Hadfields, Limited, of Sheffield, and are made of their patent manganese steel, which is so hard that it can only be ground true with the aid of an emery wheel.**

Digitized by Google

All the special work at the corners of streets and in the car-shed was laid out at Messrs. Hadfield's works prior to being fixed in position. The road between the rails and for a distance of 18in. on each side of the rail is paved with Welsh and Devonshire granite setts, except in Queen-street, High-street, Sidwell-street, and Cowick-street, and in front of several places of worship, where the granite setts are replaced with hardwood paving. The whole of High-street and parts of Queen-street and Cowick-street is paved with hardwood blocks, and this forms an incidental improvement, which is already much appreciated. The steepest gradients are as follows: Fore-street, 1 in 11½ to 1 in 13; St. David's-hill, 1 in 16; and Pinhoe-road, 1 in 19. The sharpest curves are at the corners of Queen-street and Paris-street—viz., 35ft. radius.

MR. THOMAS MOULDING, A.M.I.C.E., CITY SURVEYOR.

COUNCILLOR EDWIN C. PERRY, MAYOR OF EXETER, AND CHAIRMAN OF THE TRAMWAYS COMMITTEE.

MR. H. D. MUNRO, M.I.E.E., CITY ELECTRICAL ENGINEER.

These are arranged as centre poles, side-bracket poles, or span-wire poles, according to the requirements of the individual routes. The lines are so arranged that the trolley wheel runs centrally wherever feasible, but full advantage is taken of its swivelling power at certain points on the route. The lines are double insulated throughout. All the section boxes are connected by telephone with the generating station and the car-shed in Paris-street, and the test wires required by the Board of Trade run to the ends of all routes. The telephone and test wires are carried underground as far as the conduits extend, and are then continued by small overhead wires attached by brackets and insulators to the poles. Guard wires, as required by the Board of Trade, are fixed above the trolley lines wherever overhead telegraph or telephone wires might possibly fall upon them. Frogs, switches, and crossings are provided on the trolley lines to correspond with those on the track below.

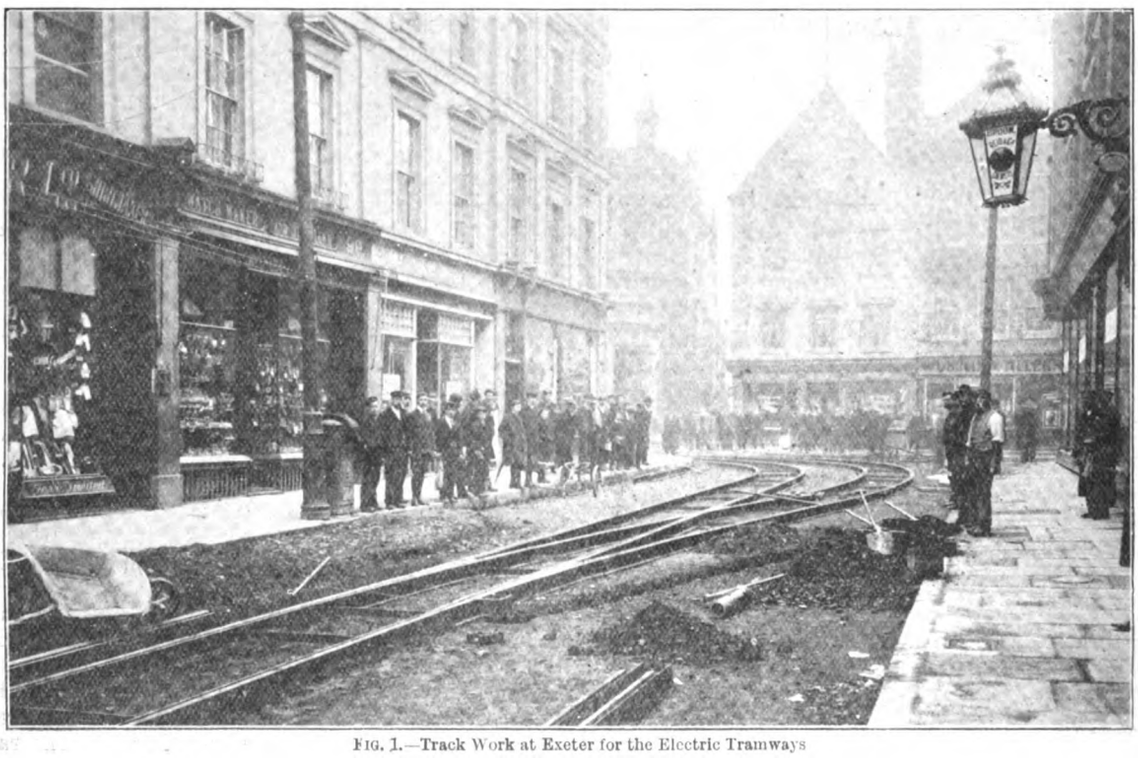

FIG. 1.—Track Work at Exeter for the Electric Tramways

The current for the tramways is conveyed from the generating station by means of lead-covered feeder cables running through stoneware conduits to section pillars, each half-mile section of route being separately supplied so as to be independent of any other section. From the section pillars the current is conducted up the poles to the overhead trolley lines, which are double throughout, and are supported from sectional steel poles.

There are for the routes now converted 12 cars (Fig. 2), built and equipped at the Preston works of Messrs. Dick, Kerr, and Co. They are of the double-deck type, with a seating capacity of 20 passengers inside and 22 outside. The stairways are of the semi-reversed type, giving increased accommodation on the roof and protection

Digitized by Google

from the weather on the platforms. The inside seating is of woven rattan cane, with perforated veneer backs, for cleanliness, and the outside seats are of the garden type, with reversible backs. The internal ventilation is by a special device of the makers, which is effective without creating draughts. Each car weighs 8½ tons without passengers, and is 26ft. long over all. They are equipped with two electric motors of 25 h.p. each. In addition to the ordinary hand-brake, they are provided with the Newell magnetic track brake, which is capable of holding a heavily loaded car upon any gradient independently of the electric power from the line. They are further provided with an electric brake which automatically

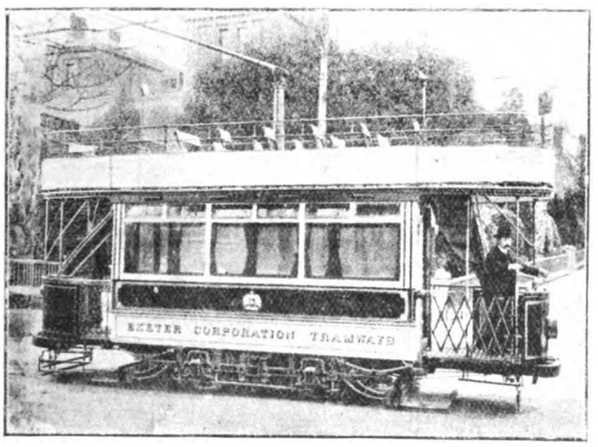

FIG. 2.—Exeter Electric Car.

prevents a car from running backwards on a gradient should the trolley come off the trolley wire. The Philipson patent lifeguard is fitted to all the cars, as also a patent folding step interlocking with the folding gate upon the platform in such a way that the step and gate open and close together. This prevents a passenger from boarding the front platform, and hence removes the cause of many accidents. The cars are thus fitted with every device which experience has suggested for the comfort and safety of the public. They are painted in dark green and gold, with the city arms emblazoned on the side panels.

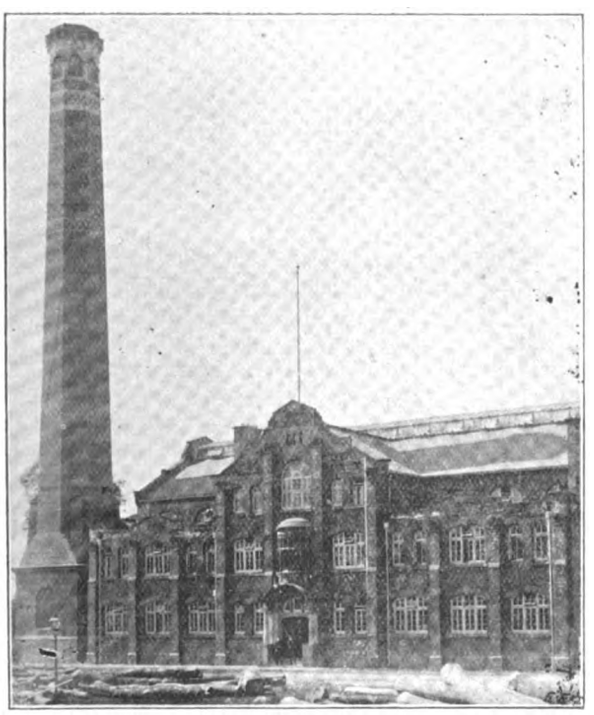

FIG. 3.—The New Generating Station at Exeter.

The car-shed and offices are located at the bottom of Paris-street, which is nearly the centre of the routes served by the tramways. The building is of brick with Portland stone dressings, the floors of the offices and stores being of wood blocks fixed on breeze concrete. The roof of the shed, which is glazed with Rendle's patent glazing, is carried on steel stanchions and steel lattice girders, with light steel roof principals. The shed provides for housing 15 cars, and comprises repair shop, smithy, paint shop, paint and oil stores, foreman's room, messroom, and general stores and conveniences. The offices have a committee-room, manager's room, general offices, conductors' room, strong-room, and necessary lavatory accommodation. The whole of the building is well lighted, and generally very conveniently designed. To provide for a possible enlargement, the south-east side of the shed has been constructed of wood between the steel stanchions, which can easily be removed when an extension is found necessary.

The following is the approximate cost of the tramways when completed throughout: track, including wood paving, £34,000; overhead equipment, £4,700; feeder cables, £3,000; cars, £7,000; car-shed, etc., £5,700; additional generating plant, £4,000. This makes a grand total of £58,400.

### THE GENERATING STATION.

The tramways are supplied with current from the new electric power station of the Corporation, opened a year ago on a site adjoining the Exeter City Basin. This is shown in Fig. 3. The buildings cover a space of 150ft. by 150ft., and are divided into bays constituting the boiler-house, engine room, and offices respectively, with annex buildings for economisers, boiler feed pumps, etc., and a chimney shaft 155ft. high, with an internal diameter of 8ft. 6in. The boiler-house (Fig. 4) is 102ft. long and 55ft. wide,

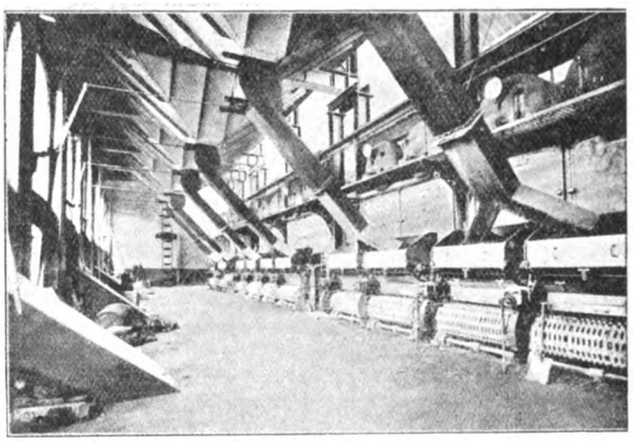

FIG. 4.—The Boiler Room, showing Coal Shoots and Babcock Chain Grate Stokers.

containing six water-tube boilers, fitted with superheaters, capable of supplying steam to engines of 2,700 h.p. A steam-pipe ring on the boiler-house wall carries the steam into the engine-room, and is so arranged that any boiler or engine can be isolated without affecting the general supply. The main flue behind the boilers carries the hot gases through the economisers on the way to the chimney. The feature of the boiler-house is the complete system for the handling of coal and its economical combustion. The coal is delivered into shoots which convey it to the automatic filler of the gravity bucket coal conveyor. This is electrically driven by a 10-h.p. two-phase motor, and conveys the coal to a series of large coal bunkers above (which will hold 500 tons), from which it is discharged in measured amounts to the hoppers of the chain-grate mechanical stokers of the boilers. These stokers, which are electrically driven by a 10-h.p. two-phase motor, in their turn automatically carry the coal into the furnaces and discharge the ashes and clinker into the basement, whence the conveyor removes them to the ash bunker. A railway siding completes the arrangements. The stokers will burn the cheapest classes of coal without smoke, and the arrangements generally represent the best modern practice for economical working.

The engine-room (Fig. 5) is a lofty and well-lighted building, 102ft. long by 45ft. wide, lined throughout with glazed bricks, with a floor of terrazzo marble paving to ensure the utmost cleanliness. Galleries are provided to give immediate access from the various offices and the boiler-house. The room is spanned by an overhead travelling crane to handle parts of machinery up to 10 tons in

Digitized by Google

weight for erection or repairs. There are at present installed four steam alternators of a total capacity of 1,300 kw., which can deal with the supply to 50,000 lamps or their equivalent. One 200-kw. steam-driven generator is provided for the tramway supply, and also a LaCour motor-generator of equal capacity which takes two-phase current from the alternators and converts it into direct current for use on the tramways. This converter, manufactured by Messrs. Bruce Peebles and Co., is a new type, possessing all the advantages of a rotary converter combined with those of a motor-generator. It avoids the use of static transformers. We hope to give a full description of this converter at an early date. Each steam alternator consists of a high-speed vertical steam-engine, with forced oil lubrication, direct-coupled to a two-phase Westinghouse alternator and exciter. The exhaust steam leaving the engines is dealt with by jet condensers in the basement, which draw their cooling water from a large well outside the building which is connected with the basin, and discharge it again into the basin after use.

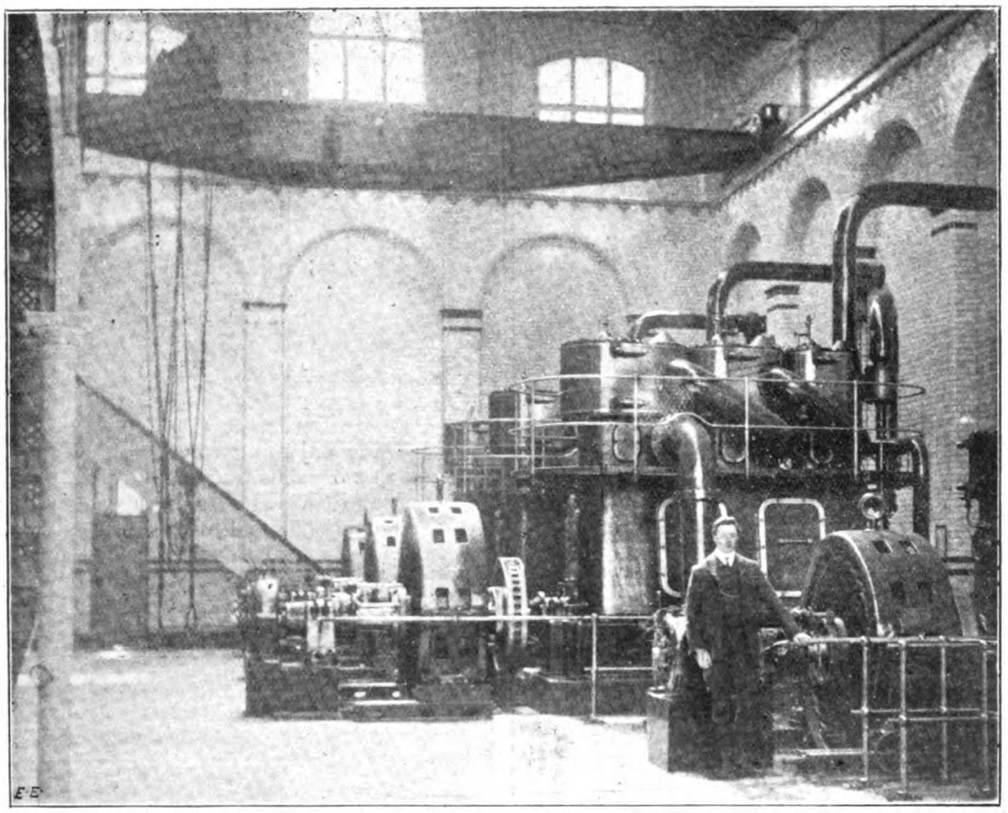

FIG. 5.—The Engine Room, showing Dick-Kerr Alternators and Howden Engines.

The current from the alternators and tramway generators is led by cables in stoneware conduits beneath the floor to the switchboards on the main gallery, from which it is distributed throughout the city by main feeder cables also laid in stoneware conduits. The Westinghouse lighting switchboard (Fig. 6) consists of marble panels for each alternator, and for each section of the main feeder cables, fitted with all necessary switches, indicating and recording instruments, and regulating apparatus. Automatic circuit breakers are used in each feeder. A separate switchboard similarly controls the tramway generators and feeder cables. They are so arranged that all parts carrying the high-

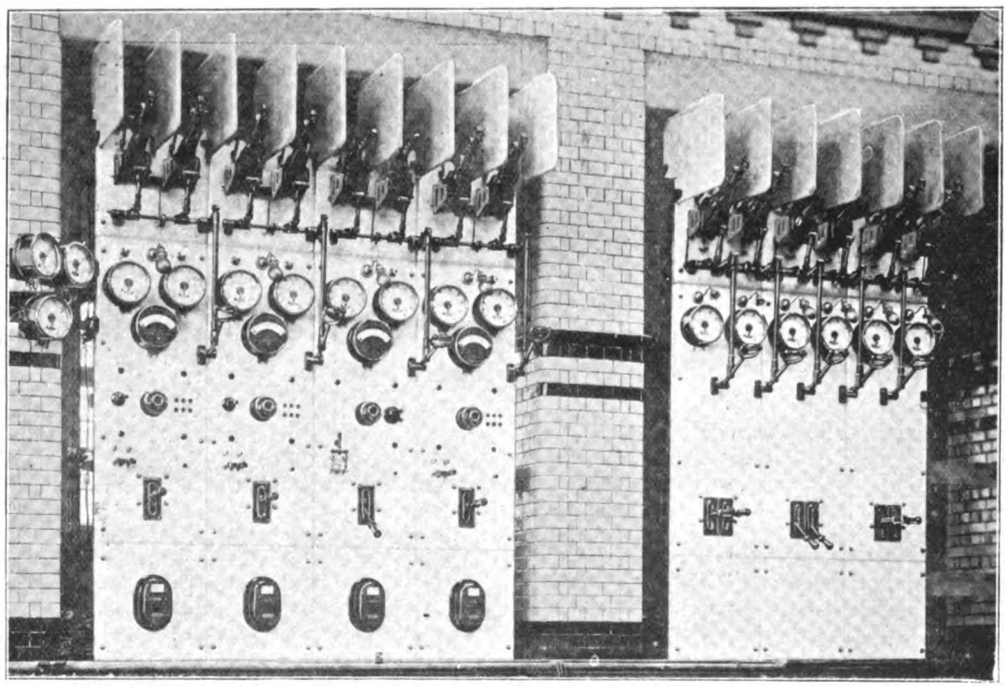

FIG. 6.—The Westinghouse Two-Phase Switchboard at Exeter.

Digitized by Google

pressure current are guarded from access by unauthorised persons, but at the same time always open to inspection.

The offices, etc., face the road, and comprise an office for the chief engineer on the second floor, a general office on the first floor, test-rooms, storerooms, messrooms for the staff on duty, entrance hall, lavatories, etc.; and there are also on the ground floor a repairs shop, fitted with electrically-driven tools, and a cable-room for testing the mains, etc. The whole station, which at present covers about one-fourth of the available site, has been carefully designed on the most modern lines to accommodate the largest machinery which the future may require, and to be capable of extension when necessary without disturbance of the original design.

The tramway load is being supplied at the rate of $1\frac{7}{8}$d. per unit for the first 100,000 units and $1\frac{3}{8}$d. per unit for all energy taken above this quantity. The meters for measuring the consumption are placed on the switchboard, and the feeders are supplied by the tramway department. The extra load will help to reduce the station costs. We have to thank the city electrical engineer (Mr. H. D. Munro) for the photographs from which our illustrations are prepared and for the information respecting the tramways and power station.

## THE WATER STERILISATION WORKS AT SAINT-MAUR.

BY EMILE GUARINI.

Experimental works for the sterilisation of water by the use of ozone were lately started at the municipal waterworks of the city of Paris at Saint-Maur. The plant is operated on Count de Frise's system. It is well known that ozone has exceptional advantages for completing the purification of drinking water. Without introducing any new element into the water, it destroys all discolouring organic matters, all unpleasant odours and tastes, and with certainty the pathogenic and other bacteria, with the exception of a few harmless spore-bearing bacilli which the water may contain. Count de Frise's ozonising plant erected on the grounds of the Saint-Maur pumping station treats filtered water of the Marne river. As it sterilises up to 150 cubic metres of water per hour, it has a sufficient capacity for the water supply of a town of moderate size.

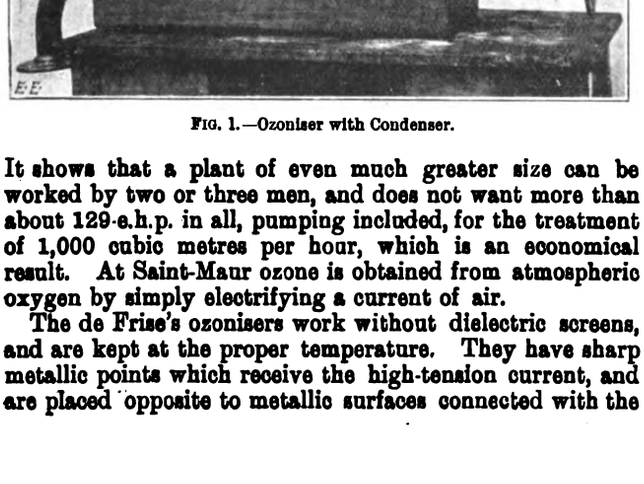

FIG. 1.—Ozoniser with Condenser.

It shows that a plant of even much greater size can be worked by two or three men, and does not want more than about 129 e.h.p. in all, pumping included, for the treatment of 1,000 cubic metres per hour, which is an economical result. At Saint-Maur ozone is obtained from atmospheric oxygen by simply electrifying a current of air.

The de Frise's ozonisers work without dielectric screens, and are kept at the proper temperature. They have sharp metallic points which receive the high-tension current, and are placed opposite to metallic surfaces connected with the earth. They are worked with tensions higher than 20,000 volts. The air is drawn through them by pumps which force it, when ozonised, through the steriliser. The apparatus are either horizontal or vertical. The vertical type occupies less room than the horizontal one, which is easier to supervise. At the Saint-Maur works the ozonisers are horizontal. There are two series of them, each consisting of three groups of three elements. Fig. 1 shows an ozoniser with condenser, and Fig. 2 an ozoniser with resistances. Each element is made of a horizontal brass half-cylindrical trough, fitted with a plate-glass cover and a cast-iron water-jacket. The trough is earthed and makes one of the poles. Across the trough at regular distances,

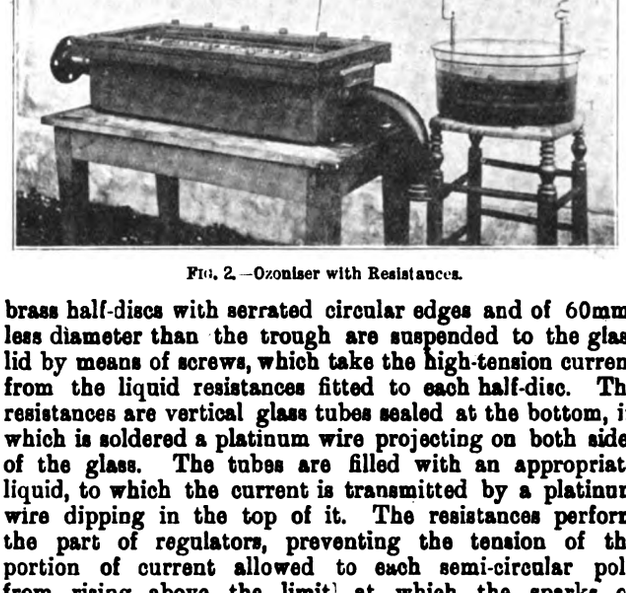

FIG. 2.—Ozoniser with Resistances.

brass half-discs with serrated circular edges and of 60mm. less diameter than the trough are suspended to the glass lid by means of screws, which take the high-tension current from the liquid resistances fitted to each half-disc. The resistances are vertical glass tubes sealed at the bottom, in which is soldered a platinum wire projecting on both sides of the glass. The tubes are filled with an appropriate liquid, to which the current is transmitted by a platinum wire dipping in the top of it. The resistances perform the part of regulators, preventing the tension of the portion of current allowed to each semi-circular pole from rising above the limit at which the sparks or voltaic arcs are produced. Silent discharges (Fig. 3) are produced between the sharp points of the semi-circular poles and the inner surface of the earthed troughs. The troughs are closed at both ends, and fitted with an air

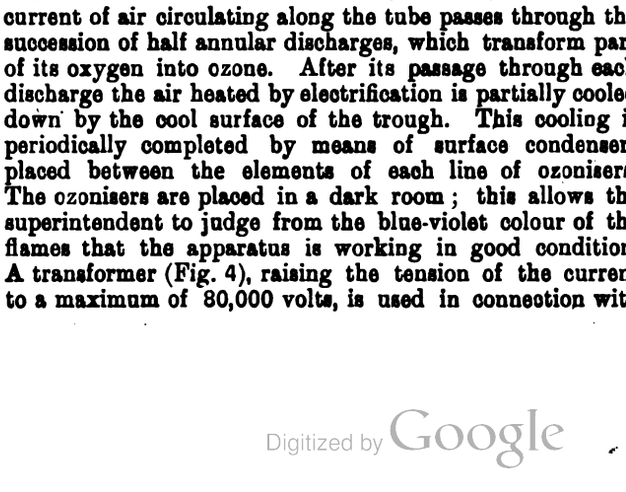

FIG. 3.—Silent Discharge.

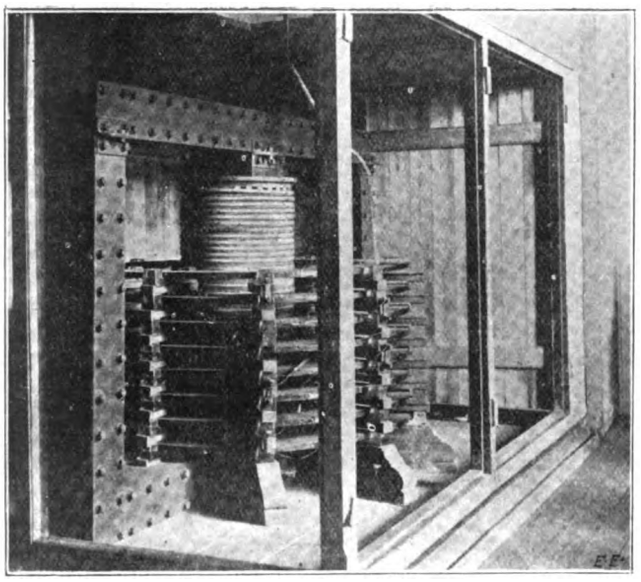
inlet at one end and an air outlet at the other. The current of air circulating along the tube passes through the succession of half annular discharges, which transform part of its oxygen into ozone. After its passage through each discharge the air heated by electrification is partially cooled down by the cool surface of the trough. This cooling is periodically completed by means of surface condensers placed between the elements of each line of ozonisers. The ozonisers are placed in a dark room; this allows the superintendent to judge from the blue-violet colour of the flames that the apparatus is working in good condition. A transformer (Fig. 4), raising the tension of the current to a maximum of 80,000 volts, is used in connection with

Digitized by Google

the ozonisers. The ozonised air is used over again and again, the inlet of the ozonisers being connected with the outlet of the sterilisers, arrangements being also provided to free the air from moisture and to make up, by fresh air, the oxygen which has been consumed in the shape of ozone.

The sterilisers (Fig. 5) are made on the washer principle. They are provided with a number of carefully levelled, finely-perforated trays, making the ozonised air bubble several times through the water. The sterilisers are cast-iron vertical cylinders enamelled inside. They are built up in parts, 50cm. high, between the flanges of which are fitted horizontal celluloid diaphragms perforated with a great number of small holes of $\frac{1}{10}$mm. diameter. The water and the ozonised air are introduced together into the lowest compartment of the sterilisers by means of an injector, which makes use of the momentum of the water arriving under pressure to assist in promoting the circulation of the ozonised air. Air and water ascend together to the top of the steriliser, being intimately mixed at the passage of each finely perforated diaphragm. The sterilising columns are fitted with inspection glasses and arrangements for collecting samples. The sterilised water flows from a general main into a tank placed in the open air, from which it goes into the covered reservoir for filtered water for supply to the city.



4.—Transformer.

A third steriliser at Saint-Maur belongs to the type in which the water is injected, in the shape of a fine spray, into the mass of ozonised air. The spray collects in the lower part of the column as solid water, into which the ozonised air is forced through the apertures of a perforated diaphragm, which makes it bubble, in minute bubbles, through the water before reaching the spray. The waste air of the three sterilisers is collected by simple connection of the outlet of the sterilising columns with the inlet of the ozonisers, to be ozonised over again. Well-balanced air-valves admit sufficient fresh air to make up any deficiency in oxygen. The ozonised air is compressed by double-acting vertical pumps of 150mm. diameter and 200mm. stroke. They draw the air through the ozonisers and force it into the sterilisers. The sterilised water-collecting tank is provided with a weir to measure the quantity of water discharged per hour.

Two rapid pressure filters (Fig. 6) are used in conjunction with the Saint-Maur ozonising plant. Each of these filters consists actually of three separate filters, built the one on the top of the other. The three have a common central inlet pipe, and each has its own bottom, its own outlet valve communicating with the discharge main, and its own outlet for cleaning water. A central shaft works the three rakes, which agitate, during the cleaning process, the crushed flint with which each filter is filled. Each triple filter is washed by revolving the agitators, and admitting, by the outlet valves, the filtered water of its neighbour under the layer of flint, through which it passes upward to be draw off by the special outlet mentioned above. The cellars contain the motor, with its shafting, a centrifugal pump to raise the water, the alternators for the ozonisers and the electrical light, two air dryers and the sterilisers, the tops of which reach the first floor. The prime mover is a semi-portable 45-i h p. steam-engine. The centrifugal pump is able to deliver 150 cubic metres of water per hour against a head of 150m.

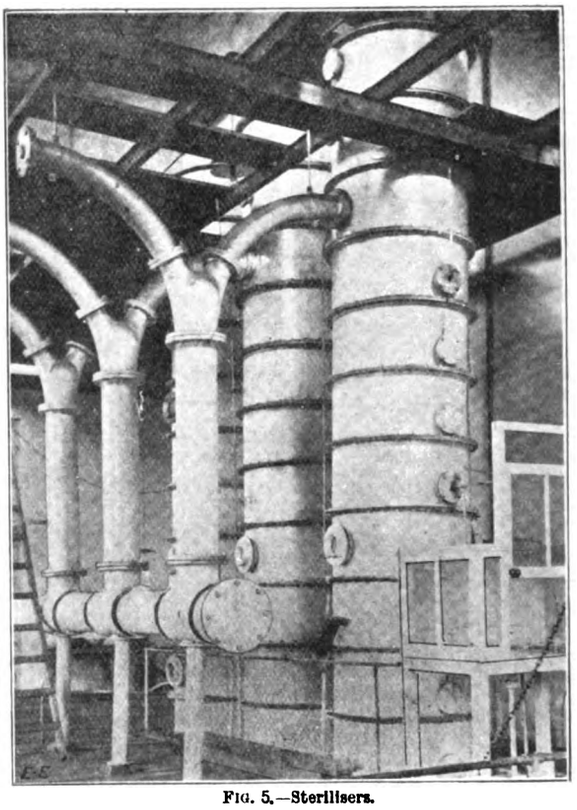


Fig. 5.—Sterilisers.

The alternators are Mordey 110-volt alternating-current machines. The ground floor contains the offices, the laboratory, the switchboard (provided with the usual fittings), the transformer, the ozonisers, and the ozonised air compressor. The first floor and part of the remainder of the building are unoccupied. The building is of sufficient size to contain apparatus for treating 30,000 cubic metres per day.

The Saint-Maur works have quite the size of a water-works destined to supply with drinking water a town with several thousands of inhabitants. It treats up to 150 cubic metres of Marne water per hour, taken either from the slow

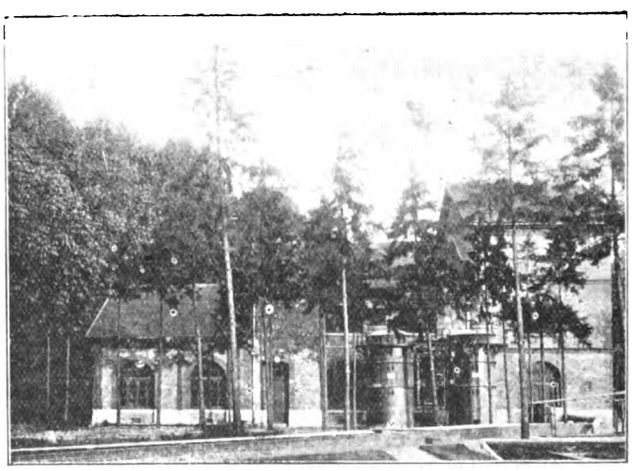

Fig. 6.—St. Maur Plant—Rapid Pressure Filters.

sand filters of the city of Paris or from the river and filtered, without adding any coagulant, by the above-mentioned mechanical filters filled with crushed flint. The system has proved quite efficient. Of five flasks tested by Prof. Bezançon, chief of the bacteriological laboratory of the medical faculty of Paris, three remained absolutely sterile, and two developed bacilli.

## THE ARNHEIM PARTY-LINE TELEPHONE SYSTEM.

The use of a single telephone line from the exchange to a number of subscribers is an obvious method of reducing the cost of telephonic connections in those cases where the use of the telephone is likely to be infrequent. The use of one line, consisting usually of a lead and a return, to supply a number of people has hence been adopted in a

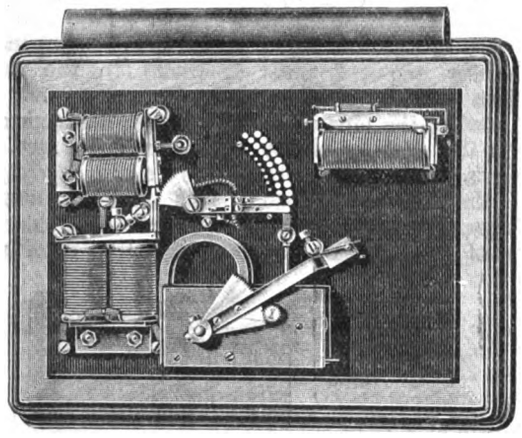

FIG 1.—The Arnheim Automatic Selector Switch.

number of districts. A good many systems of party-wire telephony have been devised in order to overcome the objections which arise from the use of the common line. In the earlier systems distinctive ringing was adopted, and when one subscriber of the group was called by the exchange, all the other subscribers on the same line would have their bells rung, but would know from the intervals in the ringing that they were not required. The fact that the bells were rung, however, was apt to call a subscriber to the instrument, and also advise him as to who was making use of the party line. This difficulty has been overcome to a limited extent by various systems of selective ringing. For instance, by using an earth connection the exchange operator could send either a positive or negative current over each of the line wires and thus give four signals, each of which would only affect one subscriber. With this system and four subscribers only the ringing difficulty was overcome. There remained the quite as serious fault that when a conversation was being conducted over the party line by one subscriber, he could be overheard and interrupted by any other subscriber who liked to remove his receiver from the hook. To obviate

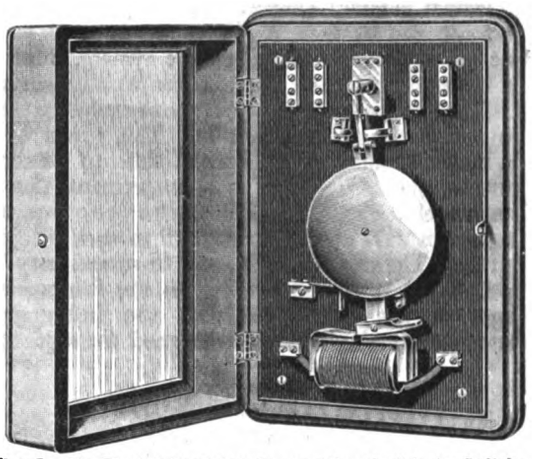

FIG. 3.—The Electric Pendulum for operating the Selector Switch.

this, a number of lock-out systems were introduced, involving a great deal of complicated mechanism requiring delicate adjustment and constant supervision. Again, with any of these systems one subscriber could practically block the line if he failed to work his instrument in the way directed.

The Arnheim party-line system, which has been developed by the Berliner Telephone Company, has been designed to overcome these shortcomings, and to make the joint use of the common line by a number of subscribers as secret as if they each had individual connection with the exchange. In a few words, this system consists of a selector switch placed at the subscriber's end of the line, from which individual lines are run to each instrument in the group. This selector switch is connected by a lead and return wire

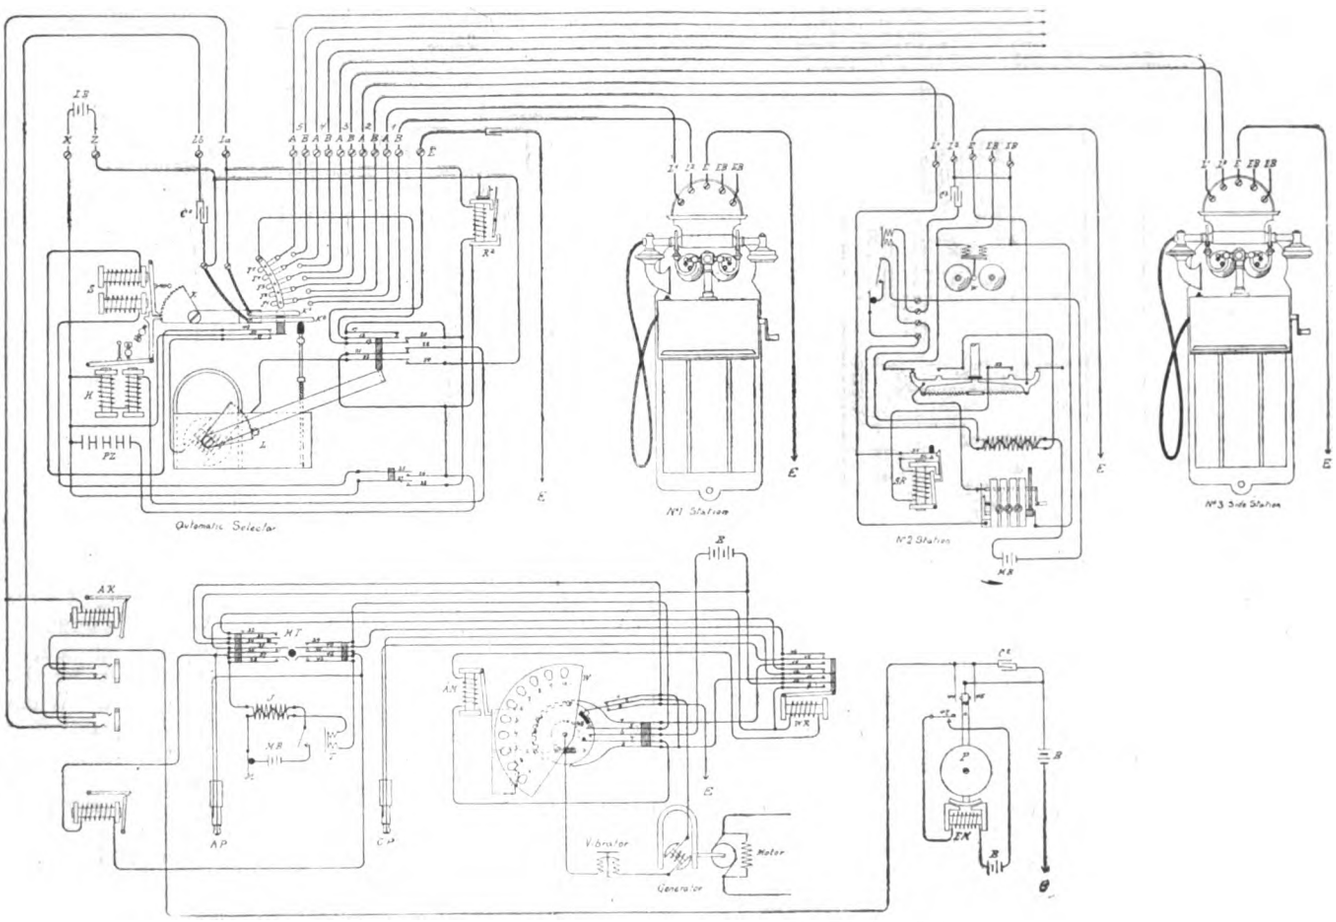

FIG. 2.—Diagram of Connections of the Arnheim Party Line Telephone System.

Digitized by Google

with the exchange. The switch can be operated by any subscriber or by the exchange, and it can only connect one subscriber at any one time on to the exchange. In the meanwhile, all the other subscribers have to wait until the conversations of the original caller is completed. This system gives distinctive ringing and absolute secrecy in speech. It is the exact opposite in this respect to the ordinary party-line system. The difference is carried so far that with the Arnheim device one subscriber of the group cannot possibly converse with any of the other subscribers supplied by the same line.

To come now to the details of the system, these will be made more clear by the illustrations which we give herewith. The two wires from the telephone exchange terminate in the automatic selector (Fig. 1). This would be placed in the block of offices or residential flats to be served by the line in question. From this instrument, the connections of which are shown in Fig. 2, two line wires, or three if the earth is not available, are led to each telephone in the group. The number which can be served may be anything from 10 to 20, depending on the frequency of the messages of the subscribers, but the instruments we inspected on Monday last were designed for a group of 10.

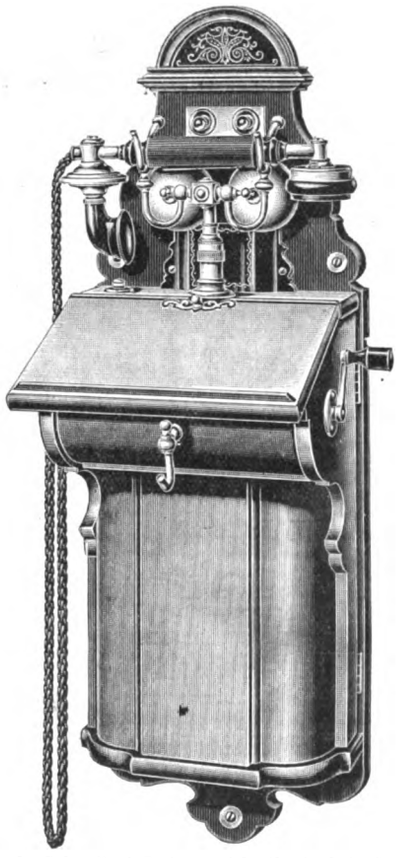

FIG. 4.—Subscriber's Instrument for the Arnheim System.

The switch in this automatic selector which connects the subscribers successively to the line, is operated through a relay by means of periodic currents from the exchange. The periodic currents are dispatched by means of an electric pendulum, seen to the right-hand side of Fig. 2, and illustrated more fully by Fig. 3. The impulses caused by the making and breaking of the circuit by this pendulum operate the sector, X, of the automatic switch, and cause this switch to move step by step over the subscriber's line wire contacts. A small dial at the exchange numbered from 1 upward is used by the exchange operator to give the right number of impulses to move the switch to the subscriber required. In the case of the subscriber a small push button only is needed to release the electromagnet locking device in the selector switch. This then moves round until it reaches the subscriber's terminals, when it is again locked. The push button on the subscriber's instrument then rises to show that the line is clear, and he proceeds to call up the exchange by the magneto in the usual way. If the push button seen at the left-hand side of Fig. 4 does not rise when the hand combination is lifted, it shows that the line is engaged. If, however, the line is clear, conversation may now proceed. At close of conversation the subscriber gives the ring-off signal to the exchange in the usual manner.

So far we have only dealt with the calling from the subscriber to the exchange. If now a call is made from the exchange to one of the subscribers of the party line, the operator inserts the plug into the party-line jack in the usual manner, and selects the party required by means of a dial (Fig. 5) provided with as many finger-holes as there are numbers on the party line. To call, the operator inserts her finger in the hole corresponding to the party required, pulls it round to the stop, and releases it. She then momentarily presses her ringing key, closing the circuit of the releasing mechanism, which allows the dial to slowly rotate back to zero. In so doing a series of contacts are made corresponding with the number selected. This allows a number of impulses to pass out on to the line, actuating the selecting relay of the automatic selector as before described, and

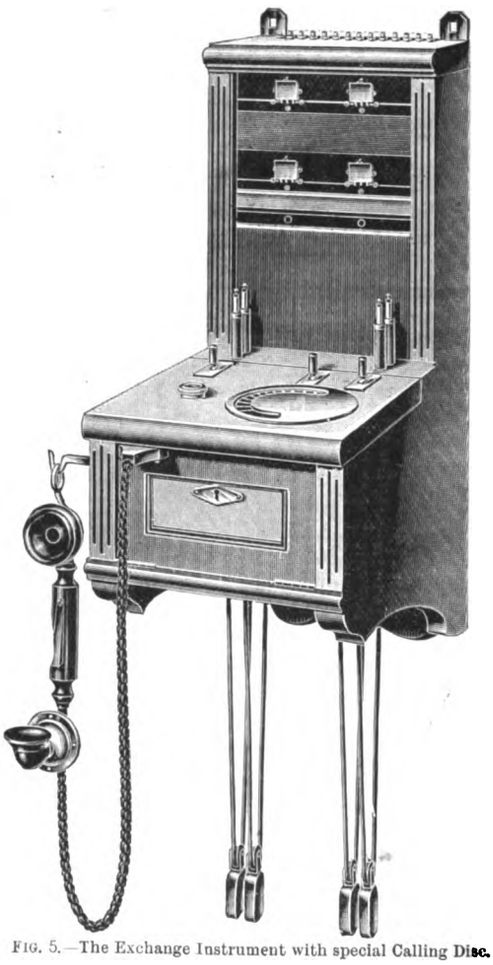

FIG. 5.—The Exchange Instrument with special Calling Disc.

causing the selecting mechanism to make a number of steps corresponding with the impulses sent. When the impulses cease, the selector, having reached the required number, is locked, and the final contact made automatically by the hand selector rings the bell of the party required. When the automatic selector leaves the rest position, a timing device is set into action which keeps the connection closed for 50 seconds, during which time, should the subscriber not answer the exchange, operator may ring him repeatedly. If at the end of 50 seconds the subscriber has not replied, the whole connections are restored automatically, and the operator is set at liberty to select any other number she may require. If, however, the subscriber answers during the 50 seconds, the contact is locked and conversation may be carried on as long as required. At the close of conversation the hand combination is replaced, and the ring-off signal given in the usual way. The operation has been detailed only for magneto exchanges, but the system is equally applicable for common battery, and as such is now being tried by the National Telephone Company at their Holborn exchange.

Digitized by Google

The method of operation is exactly the same, except, of course, the generator at the subscriber's instrument is no longer required, and the mere lifting and replacing of the receiver is all that is necessary to originate or finish a call.

It will be seen from the above that unless a conversation is actually proceeding the line cannot be blocked for more than the 50 seconds mentioned above, or other set interval as may be decided on when the adjustment of the timing device is made. In the event of a conversation lasting too long, to the detriment of other subscribers, the operator at the exchange can clear the line. This apparatus is being tried by the National Telephone Company at their Holborn exchange. It appears to us to have considerable advantages for use in residential flats, and it saves the use of the attendant now required when the ordinary extension telephones are used. That the ten subscribers on the party line cannot converse with each other is an objection to the system which will prevent friends from sharing the same party line. This fault is to be preferred to a want of secrecy.

## ADMINISTRATIVE COUNTY OF LONDON AND DISTRICT ELECTRIC POWER BILL.

(*Continued from page 482.*)

The case on behalf of the local authorities around London in opposition to this measure was concluded on Friday last.

Mr. JEEVES, on behalf of the Kingston Corporation, and Mr. READER HARRIS, for the Corporation of Ealing and the District Council of Barnes, addressed the committee against the Bill, which, they contended, would not confer benefits on their districts, but would injure them after they had incurred heavy expenditure for electrical development.

The opposition of private companies was then taken, the first witness being Sir GEORGE LIVESEY, chairman of the South Metropolitan Gas Company, who objected to the promoters acquiring compulsory powers over land belonging to his company at Greenwich, thus preventing access to the river side of their property. He had no fear of the competition of electric lighting companies, for he believed in competition, but he objected to the promoters taking the property of his company for their own purposes.

Mr. FITZGERALD, K.C., said the promoters were willing to withdraw the request to use the land, and ask only for permission to use a siding on it on arbitration terms.

Mr. BALFOUR BROWNE said the promoters were changing their front as they went along.

Mr. DEVONSHIRE, director of the North Metropolitan Electric Supply Company, which provides electricity both for lighting and power in a large area in Middlesex, Hertfordshire, and a portion of Essex, also gave evidence in opposition to the scheme, and asked that the whole of Stoke Newington should be struck out of the Bill.

Mr. FITZGERALD: Is it a financial benefit to the local authorities to supply them with electric power?

WITNESS: I think there can be no doubt about that.

Mr. MOON, K.C., objected to the witness being used for the purpose of getting evidence in support of the Bill. It was quite unfair, and it was a most inconvenient practice.

The CHAIRMAN: It may be an inconvenient practice, but it has been in operation in this committee.

Replying to Mr. Balfour Browne, WITNESS said that his company was prepared to meet all the electrical requirements of the district.

After evidence had been tendered on behalf of other companies,

Mr. BALFOUR BROWNE addressed the committee for the whole of the electric lighting companies, contending that the Bill sinned against the principles of the whole of the best legislation of London. The promoters had launched their case by making certain allegations against the London electric lighting companies, and to meet that he had shown how much capital had been expended by them to meet the requirements of the public. The competition which they had to meet should be fair, but he submitted that this Bill would expose them to unfair competition. It was the scheme of a huge combination which would result in a monopoly. He knew it was said that it would be a monopoly of cheapness, but that was always the sentiment in the mouth of monopolists. It generally ended in a monopoly of dearness.

Mr. FITZGERALD, on behalf of the promoters, contended that the Bill before the committee proposed the only proper way of dealing with the supply of electricity to the county of London and the adjoining districts. It was the only way in which they could ensure to the consumers that cheap supply which was necessary to enable the manufacturing interests in London to be on a par with rivals, whether in this country or abroad. It was only in this way that they could remove from London the reproach that electricity was dearer in the Metropolis, notwithstanding its size, than in almost any other large town in the United Kingdom. Dealing with the question of the maximum price, he observed that it must of necessity be fixed to meet the most unfavourable circumstances as against the company. The sliding scale provisions gave absolute security for equitable charges. The power asked for by the Bill to enable the company to purchase existing electrical undertakings was inserted with the object of giving opportunities to local authorities and companies carrying on their own undertakings at a loss to transfer their businesses to the company by agreement subject to the consent of the Board of Trade. Similar provisions had been inserted in other Power Bills, but the promoters did not attach any special value to it. That there was no clause in the Bill authorising the purchase of the company's undertaking by local authorities was due to the recommendation of the joint committee of both Houses presided over by Lord Cross that where public advantage could be shown powers might be given over a district, including the areas of several local authorities, involving plant of exceptional dimensions and high voltage, on conditions differing from those previously existing.

The CHAIRMAN: It is unnecessary to argue the question of making the undertakings of large companies like this purchaseable by the local authorities. The committee has no intention of departing from the recommendation of Lord Cross's Committee.

Mr. FITZGERALD then proceeded to argue that the absence of the power of purchase was no injustice, as there was nothing to prevent an existing company from keeping up its generating station, or, on the other hand, if the directors found that it would be commercially to their advantage taking a supply in bulk and giving up its own generating station and plant. When the local authority came into possession, the supply in bulk would be continued by the Administrative Company on advantageous terms, or the local authority would erect its own station. Counsel concluded his speech by contrasting the present means of supply with the facilities offered by the proposed scheme, and dwelt once more on the urgent necessity of a cheap power supply for London.

This concluded the case, the committee reserving their decision.

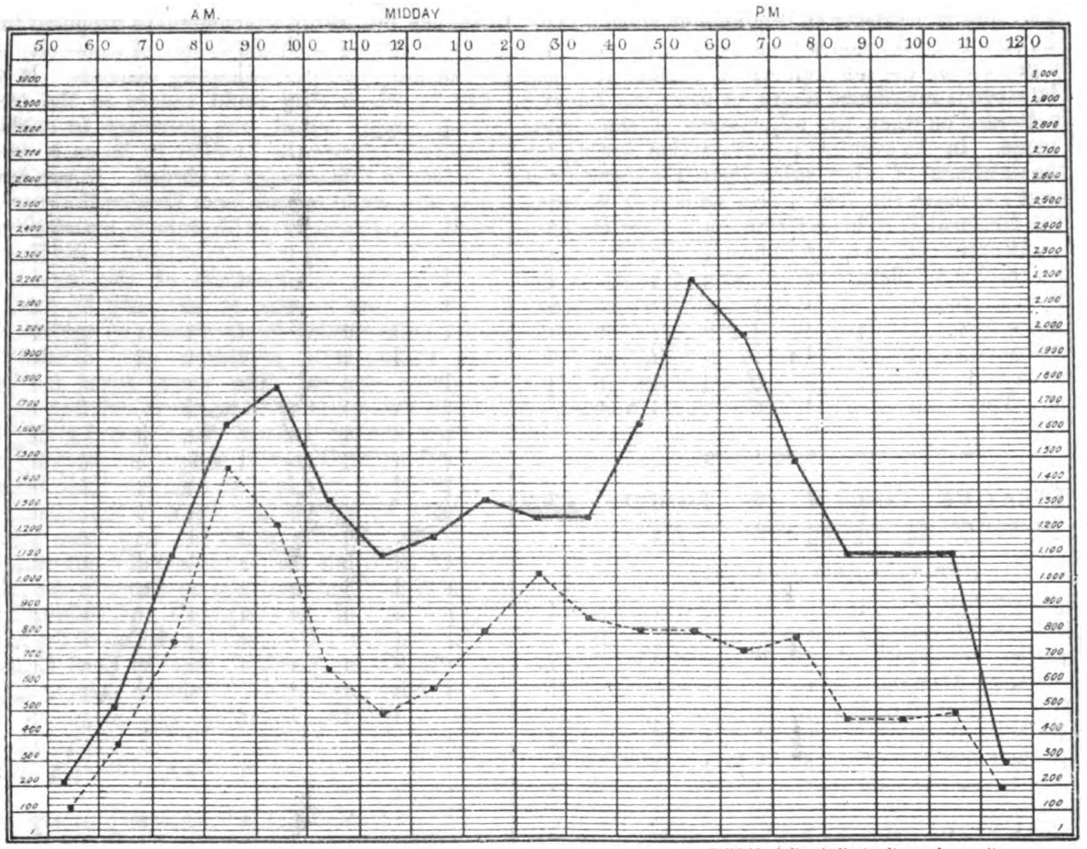
Owing to the indisposition of Lord Romilly, the East London and Lower Thames Bill will be adjourned until after Easter.

## LIVERPOOL CORPORATION TRAMWAYS.

We gave last week a brief *résumé* of the operation of this system for the year 1904, which showed excellent progress. The length of track (103 miles) was practically the same as in the previous year, but the revenue advanced from £517,935 to £557,888, although the average length of the penny stages was slightly increased. The car mileage totalled 12,166,419 against 11,724,097 for the previous year, while the passengers numbered 116,642,663 against 113,057,234. The car-mile earnings were 10·67d. against 10·34d. The total operating costs per car mile showed an increase, the figure being 7·256d. against 6·884d., and the percentage of operating costs to revenue advanced fractionally, the 65 per cent. for 1903 being increased to 65·9 per cent. The chief items responsible for the additional expenses were electrical energy, maintenance and renewal of track and cars, and rates and taxes. The gross profit totalled £190,043, against £178,124 for 1903.

Digitized by Google

After deducting interest and sinking fund there remains a balance of £81,326, out of which £54,217 is placed to depreciation, renewal, and reserve, while the rates are relieved to the extent of £27,109. We noted at the time the report of the manager upon the question of a universal 1d. fare. It was shown that the general fares in Liverpool are lower than provided under statute for workmen, and that the charge per passenger mile is the lowest in the country. The Corporation, therefore, decided to make no changes in the scale, except to adopt 1½d. stages. The social, athletic, and thrift society in connection with the tramway employés is also in a flourishing condition. A



Solid black line indicates licensed capacity
Broken .. .. .. actual passengers carried

Diagram showing the Licensed Capacity of the Liverpool Cars over a typical route in midwinter on the inward journey, and the number of Passengers actually carried.

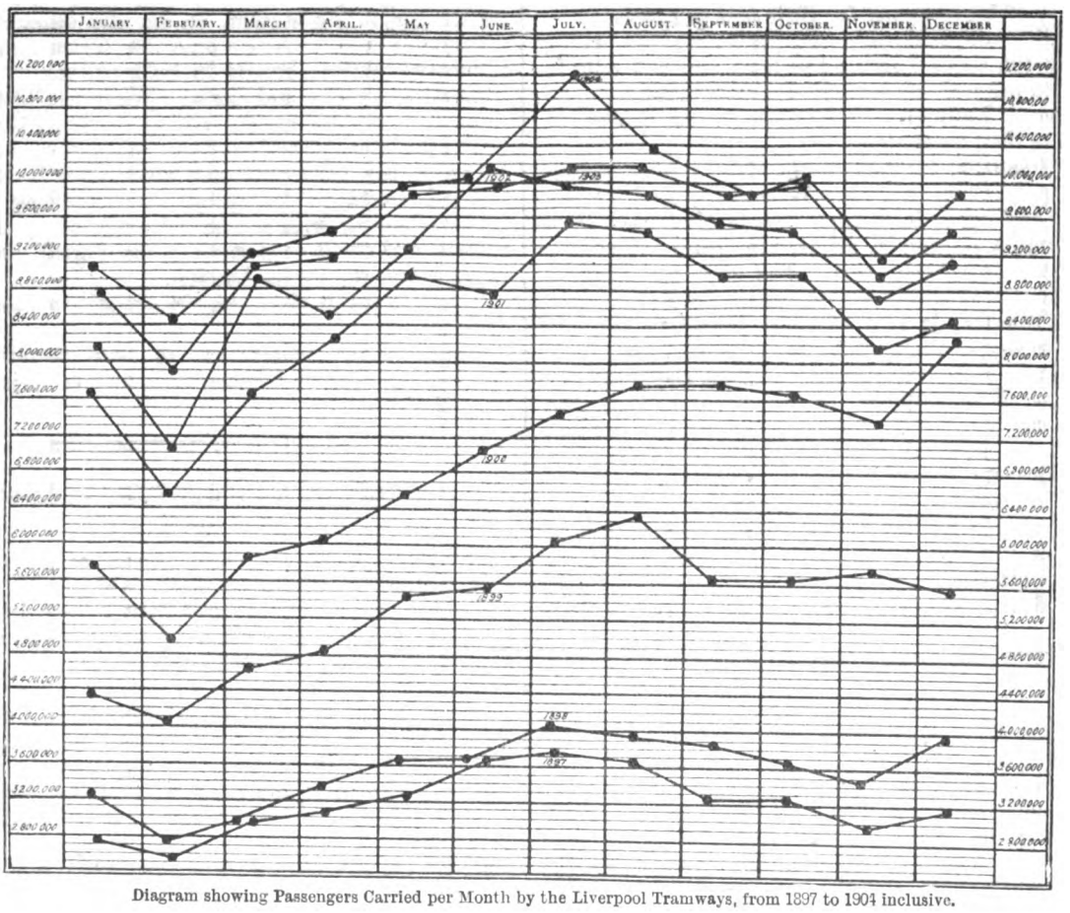


Diagram showing Passengers Carried per Month by the Liverpool Tramways, from 1897 to 1904 inclusive.

Digitized by Google

steady decrease is shown in the amount of lost property, yet the articles in 1904, which were of the usual cosmopolitan order, exceeded 10,000.

A joint report on the subject of wheels presented to the Tramways Committee in July last by the engineers and general manager states that the wheels of the German cars, which were the first to be used by the Corporation, were steel-tyred, and the wheels of the American cars, which followed, were chilled cast iron. The steel tyres were found to "spread" in running, became loose and out of gauge, and were ultimately abandoned in favour of the chilled wheel, which was giving much better results on the American cars. The British manufacturers commenced the production of special steel tyres for tramcars about 1900, when their experimental use in competition with chilled wheels began. These experiments were carefully watched, and in May, 1902, a number of selected tyres were placed in service in Liverpool, and later it was considered desirable to buy tyres of all the representative makers. Fifty-two of the cars are now fitted with steel-tyred wheels, none of which have yet worn out, and therefore final figures cannot be quoted. Very divergent results have, however, been obtained, the mileage per unit of wear varying to the extent of 50 per cent., indicating the importance of selecting tyres of suitable composition. As a result of the experiments carried out for the last two years, a steel-tyred wheel is now being assembled and finished at Lambeth-road works which will cost 50 per cent. less than the price at which such wheels can at present be brought, and which it is believed will afford a life considerably in advance of the average of these wheels, which may be estimated at 60,000 miles, the average mileage of chilled wheels in Liverpool being 35,000. Since the date of this report over 100 cars have been fitted with the new wheel, which is giving satisfactory results. The stock of cars aggregates 494, composed of half a dozen types of single-deck, double-deck, and top-covered varieties. The number of top-covered cars in service is 317, and this figure is to be brought up to 350. As showing the effect of the top cover, it is pointed out that the average maximum number of cars in service for 1904 was 398 as against 407 for 1903, while the passengers carried increased by 3,585,429. Although 123 people fell in front of the cars or were knocked down, the lifeguard operated very satisfactorily, only three cases of fracture occurring. Altogether there were six fatalities in connection with the trams, which, in proportion to the passengers, gives a ratio of 1 in 19,440,441, whereas on railways, according to the most recent Board of Trade returns, the relation is 1 in 1,030,917.

A map graphically illustrating the entire system and several interesting traffic curves accompany the report. We reproduce two of the latter, from the first of which will be seen the licensed capacity of the cars running over a typical route on the inward journey during each hour of a traffic day and the number of passengers actually carried. This curve is for mid-winter, and, taken in conjunction with the diagram for outward traffic which also appears in the series, it shows that the service provided is capable of dealing with the demand at any part of the day. In the case of the "inwards" diagram the line representing the passengers actually carried approximates most nearly to the line indicative of the maximum capacity between eight and nine in the morning, and the disparity is greatest between five and six, when the cars are entering the city preparatory to taking the passengers home. In the "outwards" diagram these conditions are naturally reversed. The second of the illustrations which we reproduce shows at a glance the progress of the system since it was taken over by the Corporation. The consistently upward tendency of the curves reflects the progressive policy which has placed, and will doubtless keep, the Liverpool Corporation in the front rank of electric tramway undertakers.

## THE MARCONI PATENTS.

The United States Circuit Court has given its decision in the case of Marconi *v.* De Forest, and the result appears to be a sweeping victory for the former. From cable advices received, the following important claims in the Marconi patent have been declared by the Court to be valid, and to have been infringed by De Forest:

"3. The combination, in an apparatus for communicating electrical signals, of a spark producer at the transmitting station, an earth connection to one end of the spark producer, an insulated conductor connected to the other end, an imperfect electrical contact at the receiving station, an earth connection to one end of the contact, an insulated conductor connected to the other end, and a circuit through the contact, substantially as and for the purpose described.

"5. The combination, in an apparatus for communicating electrical signals, of a spark producer at the transmitting station, an earth connection to one end of the spark producer, an insulated conductor connected to the other end, an imperfect electrical contact at the receiving station, choking coils connected to each end of the contact, an earth connection to one end of the imperfect contact, an insulated conductor connected to the other end, and a circuit through the coils and contact, substantially as and for the purpose described."

These claims relate to what are essential details in all wireless telegraph systems, and appear to cover the use of an aerial conductor with one end earthed. The full text of the judgment is not yet to hand, but the decision is given on such broad grounds as to veto the commercial operation of any other system in the States during the term of the primary Marconi patent.

## HUDDERSFIELD ELECTRICITY ACCOUNTS.

The accounts of the Huddersfield Corporation electricity department for the year ended Dec. 31, 1904, show a total expenditure to that date of £175,972. Appended are abstracts of the revenue account and general balance-sheet.

REVENUE ACCOUNT.

| Dr. Expenditure. | £ | s. | d. |

## ELECTRIC LIGHTING BILL, 1905.

The Government Bill which has been introduced by Mr. Bonar Law in the House of Commons is in certain respects similar to the Bill which was not passed last year owing to want of time. For instance, it contains much the same clauses for dealing with the purchase by local authorities of generating stations which are outside their areas, but which are used by a company as undertaker for the supply within their areas. Joint purchase of a large undertaking by several local authorities is also provided for, as was the case in the measure which failed to become law last year. The same provisions are also included in this year's measure to deal with the combination of a number of local authorities who may form a joint board for the supply of electricity over a large district. The vexed question of stand-by supply is again dealt with in a satisfactory way, as will be seen from the details of the Bill which appear elsewhere in this issue. The most radical difference, however, between this year's Bill and the one introduced last year lies in Clause 3, respecting the supply of electricity in bulk. It provides that the Board of Trade may by provisional order authorise any company or person to supply electricity in bulk to any authorised undertaker. If the magnitude of the proposed scheme or exceptional circumstances warrant it, the matter may still be dealt with by private Bill. There are, however, before the Select Committee of the House of Lords this year a number of Bills which, in our opinion, could have been more economically dealt with by the Board of Trade This change of procedure, if it becomes law, will save power distribution companies the extremely heavy costs which they now have to incur in committee, and will tend towards a freedom of trading in electrical energy which must ultimately prove to the advantage of all users of the same. We do not suggest that a large scheme like the Administrative County of London and District Electric Power Bill could possibly be dealt with under the proposed new procedure. It will, however, be applicable to a large number of cases where a supply in bulk between undertakers in adjacent areas is to the advantage of both. The Bill contains, under Clause 6, the terms under which the Board of Trade may dispense with the consent of the local authority to the granting of an electric lighting provisional order. The first clause of this section still leaves the local authority the veto if they are already authorised to supply electricity. This prevents competition between private and municipal enterprise, and should go far towards removing municipal opposition to the Bill. The second proviso is to the effect that when mains are to be laid in streets outside the undertaker's area of supply, the Board of Trade must make a special report and state the grounds on which they decide to dispense with the consent of the local authority interested. The wording of these clauses, in our opinion, protects those most concerned—*i.e.*, the consumers—and prevents the obstructive policy of a local authority from interfering with the development of electrical distribution. The Bill, if passed, will provide means for overcoming many proved deficiencies in the older legislation dealing with the supply of electricity. It will cheapen the cost of procedure, and hence tend to the more rapid extension of the industry. We trust that this year the Government will not allow their Supply of Electricity Bill to be massacred with the other measures which annually fail to become law owing to want of time.

## INTERNATIONAL COURTESIES.

An Englishman is never at his best till after dinner. To give a feast to a friend is his delight, and he is never

Digitized by Google

so happy as when a valued friend from another land becomes his guest. That was the condition of some thirty or forty Englishmen on Saturday last when they met at the Café Royal to entertain Mr. T. Commerford Martin, of New York, a gentleman whose kindly deeds on the other side have won him a warm corner in the hearts of all who have the pleasure of his acquaintance. The chair was occupied by Kaye Gray, the immediate past-president of the Institution, supported by his successor and the leading lights of the electric firmament. These gentlemen all came to show the high appreciation they had for the guest of the evening, and in some measure to indicate how high they valued his unceasing efforts to make their stay in the States last year and the Institution's trip to St. Louis so very successful. Mr. Martin is by birth an Englishman, by accident of residence and all that makes life dear an American, he having become a naturalised citizen of that country. Mr. Gray, at the conclusion of the dinner, gave the toast of "The King," which was loyally honoured, as was that of "The President" (Teddy the Second). *The* toast of the evening was next, and Mr. Gray and Prof. Ayrton told in simple, vivid, and eloquent words how greatly they were indebted to Mr. Martin during the sojourn in the States. Mr. Martin, in an exceedingly able speech, enthralled his audience by his earnestness in reciprocating good wishes. We are not reporting speeches, yet there was one especially good tale that must come in. Mr. Martin referred to a talk with Ingersoll, in which Martin mentioned the might and majesty of Britain, whose "drum beats are always with us." "Yes," said Ingersoll, "and so are their 'dead beats.'" Mr. Martin hoped these international visits would continue, and that, while competition led to keenness, the joining of hand to hand would bring about the heartiest good-fellowship between the kindred citizens. Colonel Crompton and Prof. Perry toasted the sister societies, to which Mr. Siemens replied. After a hearty vote of thanks to Messrs. Wetzler and Webb, who organised and did all the heavy work attached to such a meeting, the gathering broke up, after thanking the chairman, with a feeling of satisfaction that we had on this side shown in some slight degree how deeply impressed we were at the kindness showered by Mr. Martin upon those of us who had ever been brought into contact with him. May such kindly feelings never cease to flourish!

## CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

### DUNDEE POWER SUPPLY.

SIR,—With reference to the publishing of my report on motive power charges in your issue for last week, in the first introduction I notice that you have used the word "minimum" price at 2½d. per unit, whereas this should have been maximum price at 2½d. I may say that the Dundee Town Council have adopted the system mentioned for the ensuing year, and the registration of the motors has been commenced.—Yours, etc.,

H. RICHARDSON, General Manager.

Dundee, April 12, 1905.

## MANCHESTER SECTION OF THE INSTITUTION OF ELECTRICAL ENGINEERS.

On Tuesday last a paper on "Labour-Saving Formulæ in Dynamo Design" was read by Mr. Julius Frith and discussed.

Mr. H. W. WILSON criticised some points in the data for turbo-generator design, principally as to the safety of 15,000ft. per minute peripheral speed with smooth-core generators; and was reassured by Mr. FRITH that with No. 19 piano steel binding wire the factor of safety was 10.

Mr. S. L. PEARCE corroborated some of Mr. Frith's formulæ and details from actual experience. On the Metropolitan Supply Company they had experienced trouble with slot-wound turbo-machines, but now that these are smooth-core, with piano wire binding, their peripheral speed of 15,000ft. per minute is safe.

The other business of the meeting consisted in passing votes of thanks, one being to Mr. C. D. Taite for his services in the chair during the past session. This was proposed and seconded by Mr. S. L. PEARCE and Mr. E. W. COWAN respectively; and Mr. T. L. MILLER with Dr. BOWMAN dealt similarly with the acknowledgment to Mr. P. A. Ramage of his work as hon. secretary and treasurer. Mr. RAMAGE, in reply, prophesied that if the work of the section increased in the next 12 months as it had done in the past year, it would be necessary to engage a secretary with nothing else to do. The membership had increased from 549 to 764 (about 40 per cent.) in the interval mentioned.

The voting for next session's officers resulted as follows: chairman—S. L. Pearce; vice-chairman—T. L. Miller; hon. secretary and treasurer—P. A. Ramage; committee—L. Andrews, Dr. Bowman, A. A. Day, M. B. Field, A. Eckstein, A. H. Gibbings, Dr. E Hopkinson, A. B. Holmes, M. B. Mountain, G. F. Metzger, Dr. Rhodes, Dr. Schuster.

This concluded the business of the session.

## HECKMONDWIKE ELECTRICITY SUPPLY.

On Saturday last there was an official opening of the extensions of the electricity works at Heckmondwike, which have been carried out under the direction of Mr. G. H. Carter, the consulting and resident electrical engineer to the District Council. The original scheme for the lighting supply in Heckmondwike was carried out to the designs of Mr. W. C. C. Hawtayne. The works were opened on Dec. 1, 1901, when there were 39 consumers with 2,804 lamps connected to the mains. In the beginning of 1902 the Council were called upon to make provision to give a supply of electrical energy to the tramways which the British Electric Traction Company were about to construct in the Spen Valley. The Council instructed Mr. Geo. H. Carter to draw up a scheme for the supply to the tramway company, and also to deal with the increasing lighting load. This scheme included the addition of a boiler of the Babcock and Wilcox type evaporating 12,000lb. of water per hour. In the engine-room a 150-kw. set was added, the engine being of the Howden type and the dynamo supplied by Messrs. Dick, Kerr, and Co. A steam-driven surface-condensing plant, with Edwardes air-pump, capable of dealing with 10,000lb. of steam per hour was also added. In connection with the above, two tanks were fixed immediately under the air-pump delivery pipe, the delivery pipe being fitted with two lever valves, enabling the discharge water to be delivered into these tanks alternately, so that at any time a test of steam consumption can be made of any particular engine, the whole of the above and the necessary pipework being supplied by Messrs. Thornton and Crebbin, of Bradford. In connection with this condensing plant a cooling tower of the Worthington type with forced draught was placed in one corner of the engine-room. The forced-draught fan was a variable-speed one, and was driven by a Royce double-commutator motor.

In connection with the tramway supply a Highfield booster and a Chloride battery were installed, the combination being capable of giving a discharge to the line of 400 amperes as a maximum. The Tudor battery was at this time rearranged, the regulating cells being done away with and the battery being increased 40 per cent., the object being to enable the cells to be used on the Highfield system. The switchboard was also extended by the addition of five panels, and a new feeder was laid down for lighting and a large line feeder and return for the traction work. These extensions were all carried out in 1902. In the

Digitized by Google

spring of the following year the boiler-house plant had again to be increased, and this time a Stirling boiler, equipped with a superheater and chain-grate stoker, was added. Automatic stokers were also then fitted to the existing Babcock and Wilcox boiler. A 300-kw. steam set, again of the Howden-Dick-Kerr type, was added, and one more lighting feeder. In the spring of last year a second Stirling boiler, also capable of evaporating 20,000lb. of water per hour, was added. Another 300-kw. steam set was installed, this time the engine being of the Willans and Robinson type, and the generators by Dick, Kerr, and Co. The switchboard was again increased in order to provide for three new feeders. Two of these were of the triple-concentric type, and one a plain concentric cable, each conductor being half a square inch in sectional area.

Since the original scheme the street-lighting has been considerably extended, the number of converted gas-posts now being 189. The demand on the station has steadily increased, as the table given herewith will show, the number of 8-c.p. lamps now connected being 20,467, and 2,271 applied for but not connected—making 22,738, which equals a kilowatt demand of 682. Assuming 50 per cent. of these lamps to be burning at one time, the demand on the station would be 341 kw., to which must be added supply given to the tramway company—namely, 400 kw.—making a total demand of 741 kw., the capacity of the plant being 900 kw. During the time the station has been working numerous additions have been made to the network in the town, which have been carried out by the Council's own men.

Herewith is given a comparative list of figures to show the progress since the commencement of supply, when there were 39 consumers with an equivalent of 2,804 8-c.p. lamps connected.

| Date..... March 31, | 1902. | 1903. | 1904. | 1905. |
|---|---|---|---|---|
| Equiv. 8-c.p. lamps connected... | 5,739 | 7,701 | 11,700 | 20,467 |
| Number of consumers ..... | 50 | 94 | 135 | 192 |
| Motors—number and h.p,..... | 1—6 | 10—36 | 36—116 | 57—331 |
| Maximum load on station—kw. | 99 | 116 | 425 | 541 |
| Units generated..... | 37,081 | 100,434 | 334,774 | 512,080 |
| Total units sold ..... | 24,598 | 73,631 | 257,054 | 419,685 |
| Station efficiency, per cent..... | 73·2 | 87·9 | 90·2 | 91·3 |
| Works costs per units sold ..... | 1·49d. | ·87d. | ·83d. | ·60d. |
| Total costs per unit sold... ... | 1·93 | 2·06 | 1·22 | ·895 |
| Capacity of plant—kw..... | 150 | 300 | 600 | 900 |
| Financial result ..... | -£675 | -£287 | +£581 | — |

The Heckmondwike Urban District Council and its electrical engineer, Mr. G. H. Carter, are to be congratulated on the continued progress which has called for these repeated extensions. Mr. H. C. Carter is the chief assistant electrical engineer.

## FORTHCOMING EVENTS.

FRIDAY, APRIL 14.

**Institution of Mechanical Engineers.**—At 8 p.m., address by the President. Conclusion of the discussion on the "Steam-Engine Research Report," and reply by Prof. Capper.

**Royal Institution.**—At 9 p.m., "The Law of Pressure of Gases below Atmosphere," by Lord Rayleigh.

**Compatriots' Club.**—At 5.30 p.m., "The Revenue Aspect of Mr. Chamberlain's Proposals," by Sir O. J. Follett.

**Physical Society.** — "Ellipsoidal Lenses," by Mr. R. J. Sowter; "The Determination of the Moment of Inertia of the Magnets used in the Measurement of the Horizontal Component of the Earth's Field," by Dr. W. Watson; and a series of lecture experiments illustrating the properties of the gaseous ions produced by radium and other sources, by Dr. W. Watson.

**North-East Coast Institution.**—At 7 p.m., re-election of officers; "Boiler Furnaces and the Effect of Oil on their Ultimate Strength," by Mr. D. B. Morison, vice-president.

TUESDAY, APRIL 18.

**Institution of Civil Engineers.**—At 8 p.m., annual general meeting.

WEDNESDAY, APRIL 19.

**Chemical Society.**—At 5.30 p.m., general meeting.

**Royal Meteorological Society.**—At 7.30 p.m., general meeting.

**Manchester and North of England Horological Society.**—At 7 p.m., "Electric Clocks," by Mr. F. Hope-Jones (Municipal School of Technology, Manchester.)

RAILWAY SUPPLIES.—We have received from the Western Electric Company, of Chicago, a copy of their railway catalogue of electrical supplies for 1905.

## UNSOLVED PROBLEMS IN ELECTRICAL ENGINEERING.*

BY COLONEL R E. B. CROMPTON, C B, M I C E.

The electrical problems which form my subject divide themselves into two groups—those set for us by Nature herself, and which chiefly concern the scientific investigator, and those which have presented themselves to us engineers since we began to use electrical energy for man's service. Engineers are only concerned with Nature's problems so far as their investigation comes into his work when he is called upon to provide means to protect our works from damage due to her display of her electrical forces.

The problems of lightning discharges have from the very first interested us, and in these later days of large power schemes the importance of protecting our works against lightning stroke has become increasingly evident. For a long time we thought that the damage caused by lightning was confined to systems of overhead conductors, as its effect on these was at once evident, in some cases by complete destruction of parts of our circuits, in others by the breakdown of our insulation, but during our recent developments of large power schemes, employing systems of conductors to carry the energy into districts where the use of overhead conductors is inadmissible, the influence of lightning discharges, or of earth strokes connected with them, on our underground systems, has been undoubtedly the cause of many failures and interruptions to service, the investigation of which forms a problem of the first magnitude. The problem has been insufficiently investigated, but it appears probable that many of the mysterious perforations of the insulation of our underground cables are commenced by static charges due to condenser effects produced on a gigantic scale in the system.

I have been slowly gathering evidence during the last few years, and find that most of the engineers who have studied this question are in agreement with me, that our present methods of detecting or guarding against the effects of frequent and hitherto unnoticed static discharges are altogether inadequate to protect our works, and that we have here presented a question of extreme difficulty and importance. No doubt in our temperate climate these effects are not so often manifested, nor are they so important, as in the more extreme climates of America, or in the parts of India where I have had personal experience of them. It is probable that they do occur in this country, and that damage to our underground systems of mains, hitherto unexplained, are due in many cases to these atmospheric or earth discharges, but only those who, like myself, have stood in a power-house in the Himalayas and witnessed the almost continual series of discharges which follow one another so rapidly that they resemble a continuous cannonade, are able to fully realise how liable our works are to become a link in the distribution of Nature's gigantic electrical display of power.

During a recent conversation with Prof. Elihu Thomson in America we discussed this question, and he reminded me of the undoubted fact that lightning strokes as they pass through the air very frequently follow one another over nearly, if not the same, identical air path. He seems to think—but this requires confirmation—that the dielectric strength of the air at this point is reduced or partly broken down by the passage of a powerful lightning stroke, which facilitates the passage of subsequent strokes at the same point. Are we to conclude that corresponding conditions of weakened path are set up below the earth's surface, and consequently affect us by affording paths for disruptive discharge through our underground mains?

Closely allied with the investigation of these interesting phenomena are the hitherto unexplained causes of ball lightning, which appear extremely difficult to understand. We have such consistent accounts given by truthful and competent observers of balls of fire moving slowly in the air or rolling along the ground, sometimes attended with slight noise or explosion, in others by violent disruptive effects, that we cannot refuse to believe that ball lightning is a reality. I am aware that it has been asserted that

* The "James Forrest" lecture, 1905, delivered before the Institution of Civil Engineers.

Digitized by Google

they do not really exist, but are merely persistent effects on the retina produced by a previous brilliant discharge; but as Planté in his researches has distinctly stated that he was able to reproduce ball lightning effects on a small scale when experimenting with direct currents of high E.M.F. obtained from his accumulators, there can be no doubt that Nature does produce these phenomena for which at present we have no explanation to offer.

Those of us who were at St. Louis last summer witnessed the remarkable luminosity surrounding the electrical conductors carrying currents at the extremely high pressure of 100,000 volts. It appeared under those conditions of electrical stress as if the air itself became luminous, and I suggest that this may throw some light on the phenomena of ball lightning.

I cannot omit from this lecture any mention of the problems of terrestrial magnetism, as they certainly affect electrical engineering works, but our knowledge of the sources of terrestrial magnetism, and of the disturbing influences of what are known as magnetic storms, is so vague, and the hypotheses are based on such scant knowledge that I am compelled to touch on the matter very lightly. We do not know with any certainty where the magneto-motive force which produces the earth's field originates—that is to say, whether its source is within the earth itself or is situated externally to it. Quite recently it has been definitely shown that the sun has a magnetic field, for the solar corona has a very definite polar structure; but even if we agree that the sun is, like the earth, a gigantic dynamo, the magnetic effects in both cases being possibly due to their rotation on their axes, the magnetic moment of the sun must be far too small to enable it to be of itself the cause of the earth's magnetism.

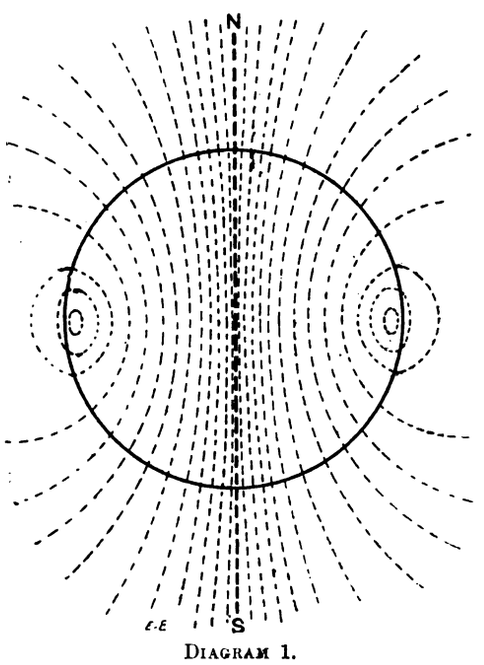

DIAGRAM 1.

There appear to be three hypotheses of the cause of terrestrial magnetism, the first being that the crust of the earth has at some time, probably shortly after solidification, become a permament magnet owing to the circulation of electric currents which possibly may have been produced by thermal causes. The second being that the cause was originally, and may still be, connected with the earth's rotation, which has gradually accumulated its magnetic field much as is the case with an ordinary self-exciting dynamo. The third hypothesis being that the sun itself is the power station for the whole solar system, and that each of the planets is merely a distributing station for the energy generated in the sun. It can, however, be shown that the direct magnetic effect of the external field produced by the sun must be small, although we know that changes taking place in the sun are unquestionably associated with the appearance of the magnetic storms which are of such importance to the navigator and the telegraphist.

The problem is undoubtedly unsolved, but great light may be thrown on it if the magnetic surveys of the inhabited portions of the globe, and especially those near the polar regions, could be completed. The diagram No. 1 shows that if we consider the earth approximately represented as a magnet with north and south poles, the lines through the equatorial zone of the earth must be directed towards the poles and recurve back from the polar areas to complete their magnetic circuit across the equator, but we have reason to believe that the earth's magnetic field is not symmetrical and differs widely from that shown in my diagram. I think that we in England may congratulate ourselves on the excellent work of our magnetic observatories at Kew and elsewhere in observing and recording variations of the earth's magnetic field over a period of years quite unbroken until the observations were interrupted by the stray magnetic field caused by neighbouring electric tramways. A new observatory is now in course of construction near the border, on the Duke of Buccleuch's estate, at which this valuable series of observations will be continued without risk of future interruption. You all know that the magnetometer observations are self-recorded on a paper strip. As Maxwell says, "On that recording paper the never resting heart of the earth traces in telegraphic symbols the record of its pulsations, and the slow but mighty work of the changes which warn us not to suppose that the inner history of our planet is ended." Surely from this long record, and from corresponding records that are being carried on in other parts of the globe, materials will be supplied to us to answer partly or wholly the problem which I have just put before you.

Another problem which is only now commencing to pass outside the domain of the physicist into that of the engineer is that of the etheric transmission of power. The development of electric wave telegraphy is an excellent instance of the various stages of the solving of an electrical problem. In this case Maxwell and Hertz settled the first stage and formulated the laws of the transmission of etheric waves. Branly supplied an important element when he invented the coherer. Marconi's enthusiasm, skill, and perseverance, aided by Fleming and other numerous competent co-workers, has carried the third stage to its present development.

We may consider that the etheric transmission of signals up to a given distance, and notably for the purposes of signalling to and between ships at sea, is practically solved, although there are many secondary problems arising out of it. No doubt the first and most important of these is the production of wave trains sufficiently powerful and of the right character to yield the best results. Fleming has particularly devoted himself to this subject, and the value of his inventions has been fully acknowledged by Marconi.

Taking the economical question first. Fleming has shown that in all probability the method that we have arrived at at our present stage of development to communicate waves to the ether by the oscillating discharge of condensers only extends over probably over 1 per cent. of the time available—in fact, that we only have a series of intermittent waves with long vacant spaces intervening. What we require is a better method of originating a continuous train of waves rather than these intermittent ones, and here we can formulate our problem, which may be solved by the mechanical engineer, or probably by the electro-chemical engineer. None of us have as yet succeeded in constructing an alternator with a frequency approaching 1,000,000 per second; but who can say that recent developments in extremely high-speed turbo-generators of the De Laval type may not furnish us with a good start in obtaining such frequency by mechanical means. Again, turning to the possibilities within reach of the electro-chemist, very promising attempts have already been made by Lodge and others to produce electrical oscillations from condensers charged by a Cooper Hewitt mercury vapour lamp. Duddell has shown by his investigation of the singing arc that herein lies a method of producing a continuous series of discharges, although in this case the frequency obtained is not sufficient for our purpose. At any rate, the solution of this problem of continuous operation by means of Hertzian waves appears to be extremely hopeful, and at any rate it is one of first importance.

One problem connected with electric wave telegraphy

Digitized by Google

requires mention, although I believe it has been already nearly, if not completely, solved by Fleming. I refer to the noise caused by the signalling spark used in wireless telegraphy, especially on board ship. The loud cracking discharge of this spark has the two-fold disadvantage of being a nuisance to anyone in the neighbourhood of the apparatus and of entirely defeating secrecy, as the message can be read by anyone conversant with the Morse alphabet. Fleming has caused the discharge to be produced in cast-iron vessels filled with nitrogen or carbolic acid under pressure, and by this means has practically succeeded in silencing the spark, even when large powers are employed.

As to the etheric transmission of power on a large scale as foreshadowed by Tesla, it is difficult to speak with any certainty, or even hopefulness. It is evident that the consequences which would follow on the etheric transmission of considerable amounts of power would be so startling, from every point of view, that they would revolutionise our ideas socially and politically, and would profoundly affect all our present conditions of life.

I now come to the second group of problems connected with the development of electrical machinery in the form that it is now taking, and with which I have personally been most in contact during the past 25 years. It is 30 years ago since we were introduced to the dynamo. We owe to Faraday, Paccinotti, Varley, Wheatstone, and Siemens the early stages of dynamo development. To those who produced our present materials, the permeable iron and steel we use for our magnet cores, the electrolytic copper we use for our conductors, we owe the second stage. We have since passed through a long series of developments of design, at first determined experimentally, and afterwards modified by practical use. The progress of our design has been marked by constant alteration following on new discoveries of systems of generating and utilising electrical energy, but throughout the considerable changes of the many systems that have been tested and which still survive, I find that underlying the whole of our progress up to the present we meet with the one mean group of problems which form the central feature of all our designs, those relating to the designs and construction of the most efficient magnetic field, and which for convenience I hereafter call the problem of "core and coil."

The electromagnet bears the same relation to electrical machinery that the cylinder, piston, and crank bear to the steam-engine. Wherever we wish to translate mechanical into electrical energy, or electrical back into mechanical energy, we are compelled to use the "core and coil," and I hope you will bear with me if I spend some of our time in discussing how much we may yet develop our future knowledge of this important matter.

Take the core first. Although in a few instances, in fact, only for measuring purposes, we use coreless electromagnetic devices, in most cases we find it necessary that a considerable part of the path of the magnetic field should lie within the metal which possesses the highest permeability for magnetic lines of force. This, up to the present, has confined us to iron in its purest form, which, when cast or produced by methods where it has been at one time in a molten condition, the engineers have preferred to call steel. In the early days of Faraday and those who followed him, it was observed that the best results were obtained when pure forge iron, such as that obtained from Swedish bars, was used for our magnet cores; but later on, in order to cheapen and facilitate construction, we commenced using cores which could be cast into the desired form. So long as these were of cast iron the permeability was low, and results therefore poor. Later on the steel-founder was able to make for us castings of high permeability; but when we began to develop the use of alternating machinery, or whenever the cores were subjected to alternating electrical stresses, we met with the difficulty that eddy currents were set up within the cores, followed by heating, and in addition we observed for the first time the losses due to hysteresis. When we first formulated our requirements for core material they were exceedingly simple. We only stipulated that it must be permeable, easily cast, forged, or worked into the shapes in which we required to use it, of sufficient mechanical strength, and easily cut or shaped up by machine tools. These requirements were easily met by the addition of small percentages of nickel and aluminium, as the use of these alloys produced cores with extreme permeability; but when, as I have just mentioned, it became of extreme importance to minimise eddy currents, we found it necessary to mechanically subdivide our cores either by slotting or sawing the solid castings or by forming our magnet arms of thin wrought-iron plates, which are held in position by being cast into cast-iron or cast-steel yokes. But at this stage we encountered an annoying difficulty, which still exists and has been the cause of much disappointment and loss to steelfounders and dynamo builders. I refer to the difficulty in producing steel castings for magnets, yokes, and frames sufficiently free from blow-holes or porosity to ensure that the magnet core portions are of equal density of mass, and, therefore, of sufficiently equal magnetic moment.

This porosity of steel castings will continue to exist so long as they are poured from steel or ingot iron comparatively free from carbon, silicon, and other materials which are present in cast iron, and thereby lower its melting-point. The purer material is so viscous that it does not run smoothly into our moulds, and consequently entraps the gases to form the blow-holes and irregularity of mass that I complain of. This difficulty is a real one, and may possibly be met by further development of Barrett's discovery that the addition of silicon in suitable proportions to cast iron renders the whole very fusible, so that complicated and difficult castings free from porosity can be made from it, but, in addition, he has shown that we have the great gain from it, as it reduces hysteresis. It is probable that the silicon acts by reducing the combined carbon that is in the iron in the form of carbide, so that the pure iron is left with a structural formation calculated to give high permeability, as it will be in the form of a sponge or network, which will give great freedom for molecular movement; moreover, at first sight we might think that pure iron would have the disadvantage of reducing resistivity, which would facilitate the formation of eddy currents, yet in practice this is not so, as although the iron has lessened resistivity, the cross-section of the filaments of the pure iron sponge are small, and therefore the mass as a whole has considerable resistance to these eddy currents. Barrett's discoveries, therefore, point in the direction from which we may hope to obtain considerable improvement in our magnet cores. We may therefore reformulate our requirements for these cores as follows: maximum of homogeneity, permeability, low hysteric coefficient, high resistance as a mass to eddy currents; of course all this combined with sufficient mechanical strength to resist the mechanical stresses due to centrifugal forces when the core forms part of the revolving mass or to the stresses set up by magnetic attraction when they form part of the frame of a stator or magnetic ring of large dimensions. In the other class of cores, particularly those subjected to alternating electrical stresses, such as the cores of transformers, we cannot hope to obtain sufficient freedom from the losses due to eddy currents by means other than minute subdivision—that is to say, by lamination, or in some cases by forming the cores of a bundle of individual wires. Great progress has been made in the production of such laminated material, and a great part of our constructive work lies in the organisation of the labour necessary to fit together the large number of sheets or stampings which go to form this class of cores. Where such cores are used for revolving armatures we meet with the secondary problem of securing satisfactory balance of the rotating mass, and it is not easy to obtain this, as any turning or cutting process applied to the edges of the thin sheets has a tendency to bring them into electrical conducting contact at the edges and ends facilitating the eddy currents. The same difficulties occur in smoothing out of the tunnels or slots of our armatures, and a satisfactory means of carrying this out cheaply and efficiently has yet to be found.

Although I am limited by time from discusing this great core question as fully as I could wish, I cannot close it without referring to the interesting discoveries of Dr. Heusler of magnetic non-iron alloys. Dr. Hadfield has produced for Dr. Fleming rings formed of an alloy of

Digitized by Google

aluminium, copper, and manganese which is nearly as magnetic as a low grade of cast iron, although it contains no iron at all. It is possible that the whole secret of magnetism is locked up in these rings; at any rate, the discovery is of extreme importance, and may have wide-reaching influences on the question of our cores.

*(To be continued.)*

## TRADE NOTICES AND NOVELTIES

### The "Velix" Watertight Electric Bell.

The accompanying illustration of the "Velix" completely-enclosed watertight electric bell, which is one-half full size, shows a useful accessory which Messrs. Siemens Bros. have put on the market. It is designed under the Hill patent, and is specially suitable for working in mines, chemical factories, powder mills, or other places where damp and explosive gases

The Velix Watertight Electric Bell.

make the ordinary electric bell either unsatisfactory in working or absolutely dangerous. The bell as designed can be worked under water. As will be seen, the whole mechanism is self-contained within the gong, which is made in the form of a hermetically sealed case. The leads enter this through a stuffing box. If desired, lead-covered wire can be used for this purpose, and the lead sweated to the case.

### Voltage Regulators.

The large variation of candle-power of an incandescent lamp with a small variation of voltage makes the satisfactory working of these lamps very dependent on the regulator of the pressure

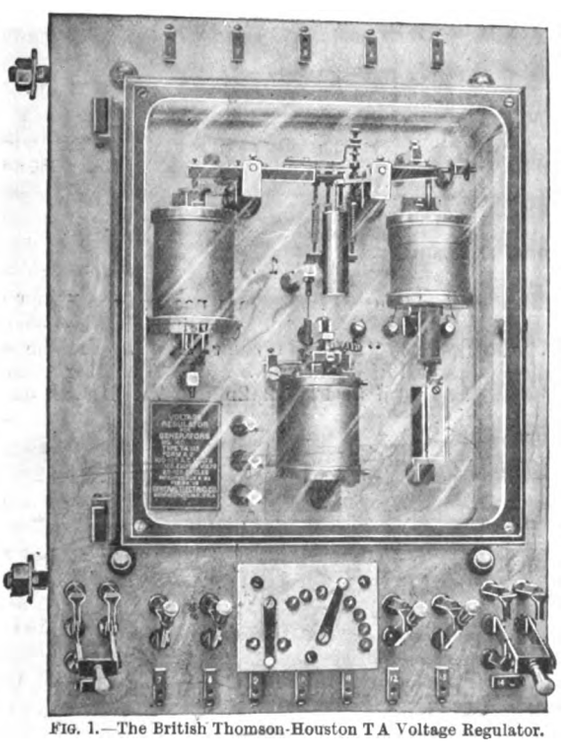

FIG. 1.—The British Thomson-Houston T A Voltage Regulator.

supply. The automatic regulation of voltage has been gone into by a large number of firms, but the latest devices for this purpose are brought to our notice by the British Thomson-Houston Company. This firm, in their pamphlet No. 178, which is just issued, describe their voltage regulator, which we illustrate herewith, and which is designed for controlling either alternating or continuous current generators. As will be seen from the diagram of connections (Fig. 2), the voltage of the alternating-current generator is automatically maintained at a constant value by varying the exciter voltage. This regulation is accomplished by rapidly opening and closing a shunt circuit across the exciter field rheostat. The rheostat shunt circuit is opened and closed by a differentially wound relay. The current for operating this relay is taken from the exciter 'bus bars, and is controlled by the floating main contacts. The current for operating the continuous-current control magnet is also taken from the exciter 'bus bars. The relay and the continuous-current control magnet constitute the continuous-current portion of the regulator, and maintain, not a constant, but a steady exciter voltage. The alternating-current

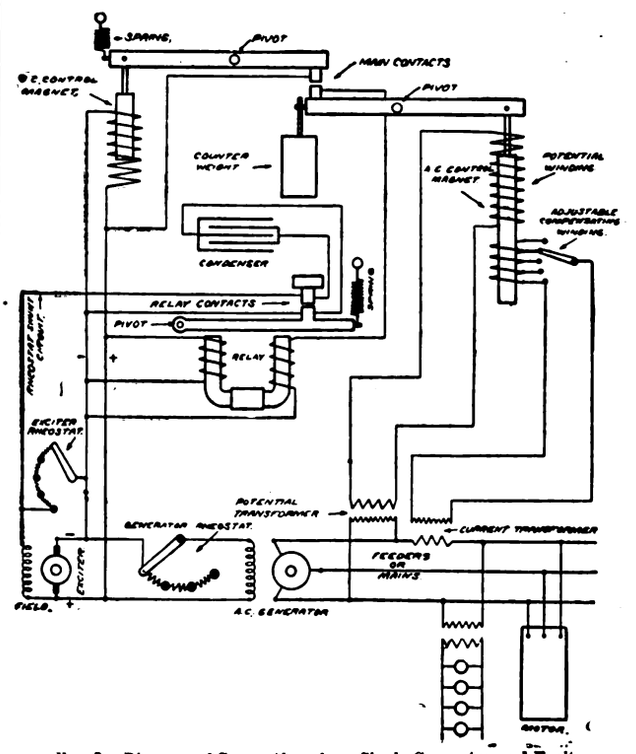

FIG. 2.—Diagram of Connections for a Single Generator and Exciter.

portion of the regulator consists of a magnet having a potential winding connected, by means of a potential transformer, to the 'bus bars or the circuit to be regulated. This magnet also has an adjustable compensating winding, which is connected in series with the secondary of a current transformer usually inserted in the principal lighting circuit. The core of this magnet is attached to a pivoted lever carrying a counterweight, which is balanced by the attraction of the magnet. If a load is thrown on the generator the voltage will tend to drop, the alternating-current magnet will weaken and destroy the balance of the core and lever, and cause the main contacts to close; this in turn will close the relay contacts and entirely short-circuit the exciter field rheostat, thus increasing the exciter voltage until the original balance of the alternating-current magnet core and lever is restored and the alternating-current voltage maintained at the required value. In some cases the exciter voltage will vary from 70 to 125 volts from no load to full load. This is especially true if the load is partly inductive and the regulator is adjusted to compensate for the line loss. It will be seen that an adjustable compensating winding is provided, so that the apparatus can be adjusted to suit local conditions. When once the regulator is adjusted to maintain a constant voltage at a given centre of distribution it requires no further adjustment, and will automatically raise or lower the station voltage as required. It is independent of the temperature rise in the alternator and also of the power factor of the load. Some interesting charts are given in this pamphlet to show what these regulators have done in the way of reducing variations in voltage.

### Catalogues Received.

THE BRITISH THOMSON-HOUSTON COMPANY have forwarded us their pamphlet No. 179, which deals with generating and sub-station switchgear. In this a large number of recently-installed switchboards are described and illustrated. The details of these various boards show how far the company have gone in the way of standardising their switchgears, and also in the development of the same for dealing with large powers. The switchboards made by the company on the remote-control principle for the District Railway Company's station at Lots-road, mark a distinct step forward in the design of such apparatus. These boards were described in our columns in the early part of the year.

CECIL HODGES AND CO. send us a large picture postcard with illustrations of the switch fuses manufactured by them on the

Digitized by Google

one side. On the other the sector voltmeter of the type now standardised for central-station work appears. These post-cards make an excellent reminder of what a firm is doing.

LUNDELL MOTORS.—Messrs. J. H. Holmes and Co. have published a new edition of their catalogue describing the Lundell patent continuous-current motors, and also those of the Castle type. We notice in the design of these motors that certain modifications have been made, and the illustrations show some new departures in the coupling of such motors to their work. One type of gearing, in which a worm and wheel is used, is especially adaptable in those cases where high-speed reduction is a necessity. The last part of the list deals with smaller motors for driving fans and to the adaptation of large motors for induced-draught apparatus.

THE EDISON AND SWAN COMPANY have just issued two new leaflets, dealing respectively with the "Triton" extension box and the "Clincher" wall plug. The first-mentioned accessory is specially designed for those installations where the looping-in of wires is insisted upon as a means of avoiding joints. The box also affords a ready means of testing without interfering with the fittings or the insulation wire. If desired, this box can be provided with an iron cover. The wall plug supplied under the name of the "Clincher" is so designed as to give a secure hold in a wall with a minimum amount of damage to the same.

MESSRS. FERRANTI LIMITED's list of moving-coil instruments for continuous currents illustrates a type of meter which is 11in. in diameter. These instruments have a small coil moving in a permanent magnet field. In order to completely shield the instrument from stray magnetic fields, the cases are made of cast iron. The instruments are provided with either front or back terminals as desired.

FANS.—Cyclone fans for induced draught are the subject of a pamphlet recently issued by Messrs. Matthews and Yates, Limited, Swinton, Manchester. Some useful notes are included, with illustrations showing the various ways of installing the fans.

ACCESSORIES.—Messrs. Davies, Kent, and Stewart, Limited, 17, Berners-street, Oxford-street, W., have sent us a comprehensive catalogue of the electrical accessories which they supply.

MEASURING INSTRUMENTS.—The latest list issued by Messrs. Ernest F. Moy, Limited, London, deals with measuring instruments of the sector and illuminated dial types for continuous current.

## PERSONAL.

Mr. B. Pontifex has severed his connection with Messrs. G. N. Haden and Sons, of Trowbridge, Wilts.

The Carlisle City Council have increased the salary of the deputy electrical engineer, Mr. G. G. Scurfield, from £150 to £175 per annum.

The Bermondsey Council have appointed Mr. W. E. J. Heenan, at present borough electrical engineer of Southend, electrical engineer at their electricity works.

Mr. W. J. Vincent, shift engineer at the Portsmouth Corporation tramways power station at Fratton, has been the recipient of a handsome marble clock, presented on the occasion of his marriage by the staff of the station.

We learn that Mr. F. A. Glover, managing director of Messrs. F. A. Glover and Co., Limited, electrical and mechanical engineers, Vine-street, Clerkenwell-road, London, E.C., is to be married on Thursday, April 20. He is giving the whole of the staff and employés a holiday on that day, therefore the offices and works will be closed.

In consequence of the resignation of Mr. W. J. Hosgood, resident engineer and locomotive superintendent, Port Talbot Railway and Docks Company, the following appointments have been made: Mr. W. Cleaver to be engineer and Mr. A. H. Hertz to be locomotive superintendent.

## APPOINTMENTS VACANT.

**Assistant Lecturer in Engineering,** Swindon Education Committee. Salary, £150 per annum. Applications by April 29. See advertisement in last issue.

**Agents** for switchboards, transformers, instruments. See advertisement in last issue.

**Pupil,** L. H. King, Council Offices, Whitby, Yorkshire. See advertisement in last issue.

**Assistant Foreman for Overhead Line,** Tramways Department, Blackburn Corporation. Wages, 30s. a week. See advertisement.

**Men** to take charge of motor pumps, Canterbury Corporation. Wages, 22s. 6d. per week of 56 hours. See advertisement.

**Assistant Electrical Instructors** in machine drawing and construction and in electric machine testing, City and Guilds Central Technical College. £150 per annum. See advertisement.

**Jointer,** Elland Urban District Council. See advertisement.

**Canvasser,** National Electric Supply Company, Limited, Preston, Lancs. See advertisement.

**Premium Pupil.** See advertisement.

**Junior Assistant.** £1 per week. See advertisement.

## ELECTRICALLY-DRIVEN LIFTS.*

BY F. O. HUNT.

*(Concluded from page 492.)*

*Brakes.*—In the early days of electrically-driven lifts brakes were exclusively a mechanical matter, and are so still in many cases where hand-rope control is adopted. When either system

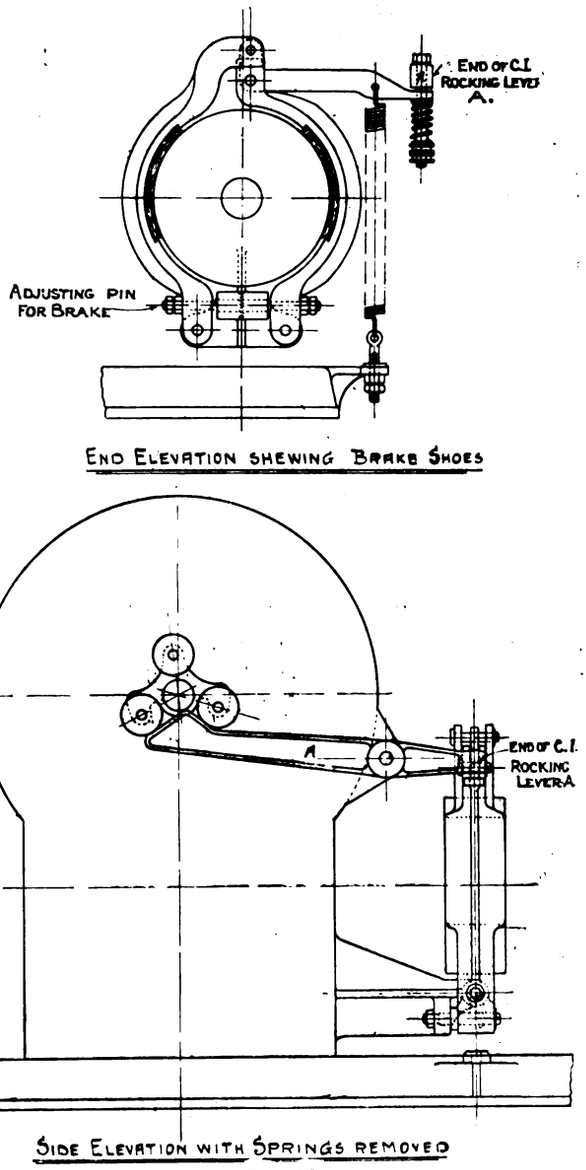

FIG. 12.

of electrical control is used, it becomes necessary to lift off the mechanical brake magnetically, thus ensuring that when current is "off" the brake is "on," and *vice versâ*. An example of a brake for mechanical lifting is shown in Fig. 12. Magnetically-lifted brakes are shown in Figs. 2, 2D, and 7A. In the design

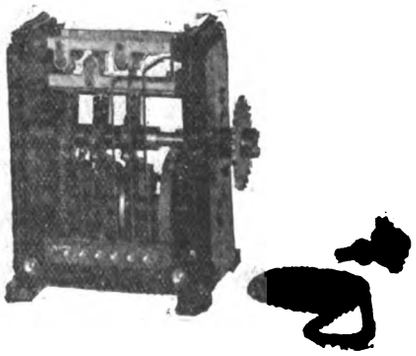

FIG. 13E.

of magnetically-lifted brakes there appears to be still room for improvement in the direction of arranging the link-work so that the solenoid has a considerably greater mechanical advantage at the beginning of its travel than at the end, thus com-

* Paper read before the Newcastle Local Section of the Institution of Electrical Engineers, March 20.

Digitized by Google

pensating for the unfortunately inherent property of the solenoid that its pull is weakest where it is desirable that the greatest force should be available.

The toggle has been a favourite motion with most of the makers, and yet in this respect it is about as bad as anything can be.

The supplementing or replacement of the mechanical brake by a retarding device depending on electromagnetic action, due to the motor being used as a dynamo, is a development which is growing in favour, and undoubtedly further changes in the same direction may be expected in the near future. The facts that such a device can be made much more even in its action, and is capable of much finer adjustment than any brake depending on an erratic coefficient of solid friction, are strong points in its favour. Where only mechanical braking has been used, the writer has seen the end of the motor shaft twisted off by the action of the momentum of the armature combined with an excessively severe application of the brake. This latter circumstance is always liable to occur owing to the anxiety of the maker of the hoisting gear to reduce the error in stopping at floors to a minimum. The ideal brake evidently should be such that the armature will be caused to dissipate the whole of its own kinetic energy in the same time that the mechanical brake is performing a similar office for the mechanical parts of the system, thus relieving the motor shaft from all twisting stresses no matter how quickly the stopping may be done. The limit of negative acceleration imposed by the safety and comfort of the passenger could then be easily reached without undue stresses upon the winding machinery. Where push-button systems are in use the range of error in the stopping point becomes rather an important matter. Fig. 9c is of interest as showing one maker's method of causing the cage to adjust itself to the floor by automatic reversal of the motor if over travel takes place beyond a predetermined limit. Some makers provide two additional buttons in the cage to enable the user to adjust its position with regard to the floor. What really is required in such a case is a method of varying the braking effect according to the load in the cage. This problem is complicated by the fact that it is usual to overbalance the lift to the extent of approximately half the load. Thus the same amount of work is required from the motor when lifting the cage with full load and when lowering it empty, so that the change of tension in the hoisting ropes is not available as a means of varying the amount of the braking forces. A method which to some extent meets this difficulty has been developed by the Otis Elevator Company, but the writer is unfortunately unable to give details of the apparatus.

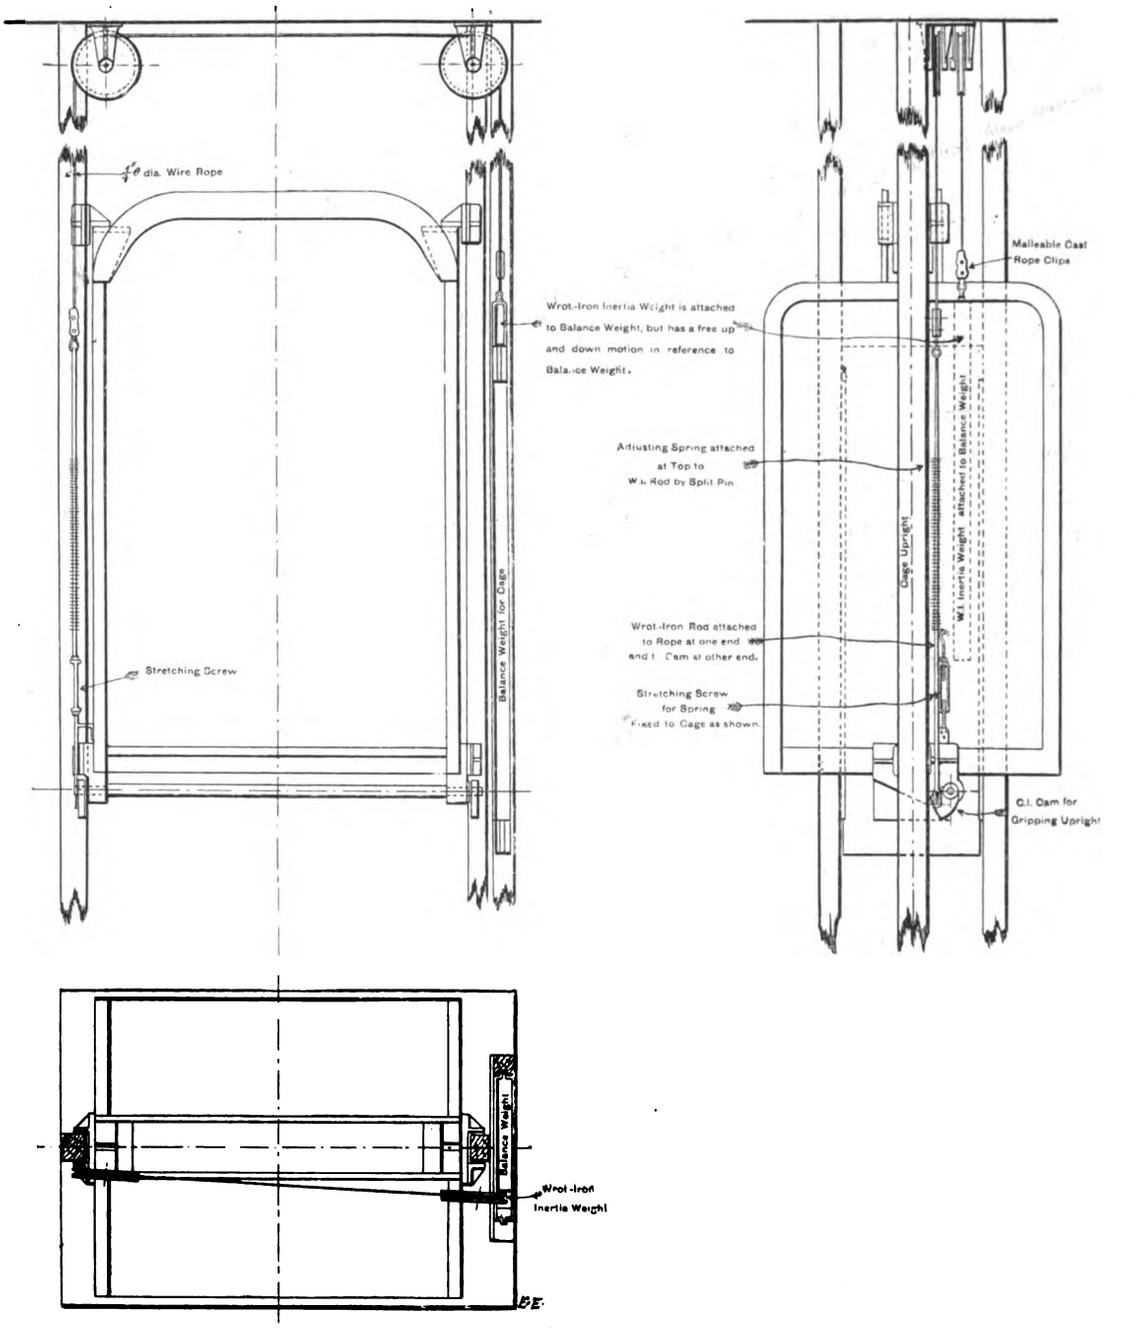

FIG. 14

*Safety Devices.*—These naturally fall more especially on the mechanical side of the work, but in the matter of preventing the cage from exceeding its proper limits of travel at either end of its range of motion, co-operation between the two designers is again necessary. Here, again, considerable difference of opinion and practice prevails. Fig. 13E represents one form of limit switch specially designed for its work, but too often the limits are controlled by ordinary hand switches with a makeshift lever attachment.

There are two guiding principles which, in the writer's opinion, should be kept well to the front in deciding these matters. They are: (1) that the mechanism between the safety device and that which it is intended to protect should be as small in amount and as simple as possible; (2) that, as far as can be foreseen, a defective piece of apparatus should cause the safety gear to act. The latter is simply a paraphase of the principle

Digitized by Google

adopted in railway signalling, where a defective signal is taken to be a signal at danger.

The prevalent practice of working limit switches by means of sprocket chains, and that of putting an excess-speed preventer on the motor or gear, both seem to be contravention of rule No. 1. Fig. 14, although not in any way an electrical matter, is inserted as an illustration of a neat way of making a safety device depend directly on the thing to be guarded. The pull of the small weight on the auxiliary wire cord is balanced by the tension of the spring attached to the cage. Any abnormal increase in the downward speed of the cage involves an increased pull to accelerate the hanging weight, and the consequent extension of the spring applies the safety clutches beneath the cage. Door contacts and electrical-controlled locks are devices where the second principle requires to be especially kept in view.

It will be noticed that in all directions the necessity for improved co-relation of the various parts has resulted in an increase in the use of electrical apparatus for duties formerly fulfilled mechanically.

The illustrations have been lettered according to the names of the makers supplying them—as follows: Number only, Messrs. Pickerings, Limited; (A) the Otis Elevator Company, Limited; (B) Messrs. R. Waygood and Co., Limited; (C) Messrs. J. Richmond and Co.; (D) Messrs. A. Smith and Stevens; (E) the Electrical Company, Limited; (G) Messrs. Geipel and Lange. Information was also supplied by Messrs. Laurence, Scott, and Co. and the Auto-Controller and Switch Company.

In conclusion, the writer wishes to express his great indebtedness to the above-named firms for their kindness in answering many questions, and for the loan of illustrating blocks and photographs; and to Mr. Sant, of Messrs. Pickerings, Limited, for kindly criticisms and suggestions in the initial stages of the paper.

## HANLEY ELECTRICITY ACCOUNTS.

The accounts of the Hanley Corporation electricity department for the year ended Dec. 31, 1904, show a total expenditure on capital account to that date of £87,790. Abstracts of the revenue account and general balance-sheet are appended, together with the statement of electricity generated, sold, etc.

REVENUE ACCOUNT.

| Dr. Expenditure. | £. | s. | d. |
|---|---|---|---|
| Generation of electricity | 4,894 | 15 | 6 |
| Distribution of electricity | 790 | 7 | 9 |
| Attending and repairs to public lamps | 386 | 16 | 0 |
| Rents, rates, and taxes | 1,087 | 6 | 0 |
| Management expenses, salaries, etc. | 1,187 | 6 | 7 |
| Special charges, insurance, etc. | 38 | 6 | 9 |
| Total expenditure | 8,384 | 18 | 7 |
| Amount carried to net revenue account | 6,892 | 15 | 1 |
| | £15,277 | 13 | 8 |

| Cr. Receipts. | £ | s. | d. |
|---|---|---|---|
| By sale of current per meter | 12,161 | 10 | 8 |
| Public lighting | 2,405 | 13 | 10 |
| Rental of meters, etc. | 333 | 12 | 5 |
| Sale and repairs of other apparatus | 368 | 4 | 1 |
| Received from accident insurance company | 8 | 12 | 8 |
| | £15,277 | 13 | 8 |

GENERAL BALANCE-SHEET.

| Dr. Liabilities. | £ | s. | d. |
|---|---|---|---|
| Capital account—amount received | 75,009 | 0 | 0 |
| Overdraft on account of loans sanctioned | 12,781 | 8 | 10 |

| Sundry debtors for current supplied | 5,571 | 19 | 4 |
| Other debtors | 168 | 3 | 9 |
| Reserve fund—balance at bank | 124 | 0 | 2 |
| Loans repaid | 1,084 | 6 | 1 |
| Amount carried to net revenue account | 204 | 2 | 2 |
| | £113,078 | 17 | 4 |

STATEMENT OF ELECTRICITY GENERATED, SOLD, ETC.

| | | |
|---|---|---|
| Quantity generated in B.T.U. | | 997,933 |
| Quantity sold { Public lamps | 182,470 | 844,272 |
| Quantity sold { Private consumers by meter | 661,802 | |
| Quantity sold on works | | 23,500 |
| Total quantity accounted for | | 867,772 |
| Quantity not accounted for | | 130,161 |
| Total maximum supply demanded (kilowatts) | | 795 |

Number of public lamps, 358.

## SUPPLY OF ELECTRICITY BILL.

The text of the Government Bill (presented by Mr. Bonar Law and supported by the Solicitor-General) to amend the Acts relating to electric lighting has just been published. The measure consists of 15 clauses and a schedule, and is intended more especially to regulate such matters as the compulsory acquisition of land for generating stations, the breaking up of streets outside the area of supply, supply in bulk, revision of maximum prices, and the certification of meters. There are also provisions as to the rights of local authorities to purchase, and as to the exercise of electric lighting powers by authorities jointly. As this measure affects all electrical undertakers, we reproduce herewith the most important clauses in full.

*Clause* 1.—*Compulsory Acquisition of Land for Generating Stations*—(1) The Board of Trade may by provisional order authorise any local authority, company, or person who are authorised by the same or any previous provisional order or by Act of Parliament to supply electricity in any area, to acquire compulsorily, or to use for the purpose of a generating station, any land specified in the order, whether situated within or without the area of supply, and in the case of a local authority, whether situated within or without their district.

(2) For the purpose of the acquisition of land authorised to be taken compulsorily under any such provisional order, the provisions of the Lands Clauses Acts which relate to the purchase and taking of lands otherwise than by agreement, and to the entry upon lands by the promoters of the undertaking, are, subject to the modifications set out in the schedule to this Act, incorporated with the Electric Lighting Acts, as well as the provisions of those Acts already so incorporated by the Electric Lighting Act, 1882.

(3) Rules made by the Board of Trade under Section 5 of the Electric Lighting Act, 1882, shall provide for proper notice being given of an application for a provisional order by which it is proposed to acquire compulsorily, or use land for the purpose of a generating station to owners, lessees, and occupiers of land, and also for public notice being given of the proposal by advertisement.

(4) The incorporation of the provisions contained in the schedule to the Electric Lighting (Clauses) Act, 1899, with a provisional order authorising the compulsory acquisition or use of land specified in the order for the purpose of a generating station shall not have the effect of incorporating Section 81 of that schedule with so much of that order as authorises such acquisition or use.

*Clause* 2.—*Breaking-up Streets, etc., Outside Area of Supply*—For the purpose of enabling electricity to be brought into the area of supply from a generating station situated outside that area, the Board of Trade may by provisional order apply to any roads, railways, or tramways situated outside that area the provisions of the Electric Lighting Acts which authorise, or enable the Board of Trade to authorise, the breaking up of any road, railway, or tramway so far as those provisions do not already so apply.

*Clause* 3.—*Supply in Bulk*—The Board of Trade, unless they are of opinion that, by reason of the character or magnitude of the proposed undertaking, the matter ought to be dealt with by private Bill may by provisional order: (*a*) authorise any company or person to supply electricity in bulk to any local authority, company, or person authorised to supply electricity in any area for the purpose of distribution by that local authority, company, or person within that area; and (*b*) provide for any supply so authorised being compulsory; and (*c*) define what are to be the limits of supply for the purpose of the provisions of the Gasworks Clauses Act, 1847, incorporated in the Electric Lighting Act, 1882, in the case of a company or person so supplying electricity in bulk; and (*d*) make such other provisions as appear to them necessary for adapting the Electric Lighting Acts to any case where a company or person are authorised to supply electricity in bulk in any area; and (*e*) authorise any local authority to supply electricity in bulk to any other local authority.

*Clause* 4.—*Provisions as to right of Local Authority to Purchase*—(1) The Board of Trade may by a provisional order authorising a company or person to supply electricity in bulk only exclude the application of the power of purchase given by Section 2 of the Electric Lighting Act, 1888, as respects the whole or any part of the undertaking authorised by the order, but before doing so shall cause notice to be given to any local authorities who would have the right to purchase under the said section, and shall consider any objection made by any of those authorities.

(2) Where any generating station, mains, or other works of a company used solely for supplying electricity within the district of a local authority are situated outside the district of that local authority, the generating station, mains, and other

Digitized by Google

works so used shall for the purposes of the provisions of the Electric Lighting Acts, and any provisional order conferring on local authorities power to purchase undertakings, be deemed to be situated within the district of that local authority, and where any generating station, mains, and other works are used solely for supplying electricity within the districts of two or more local authorities, but are not situated within any of those districts, the Board of Trade may on the application of all or any of those authorities by provisional order make such adaptations in the provision as the circumstances of the case may require. Provided that this sub-section shall not, without the consent of the company to which they belong, apply to any generating station, mains, or other works authorised by a special Act before the passing of this Act.

(3) Any local authority having power under the Electric Lghting Acts or any provisional order to purchase so much of the undertaking of a company as is within the district of that local authority may, with the consent of and upon such terms and conditions as may be approved by the Board of Trade, and with the consent of the company, transfer their rights of purchase to any other local authority having power to purchase so much of the same undertaking as is within the district of that last-mentioned local authority, and the deed of transfer may contain such consequential provisions as may be necessary for giving effect to the transfer.

*Clause* 5.—Deals with the exercise of electric lighting powers by authorities jointly, for which the consent of the Local Government Board has to be obtained.

*Clause* 6.—*Provision as to Consents of Local Authorities to Grant of Provisional Order*—(1) The Board of Trade shall, on considering whether any provisional order should or should not be granted, take into consideration the views of the local authorities affected on the subject, but whether the consent of any local authority is or is not given, may, notwithstanding anything in Section 1 of the Electric Lighting Act, 1888, grant the order or not at their discretion. Provided that (*a*) this sub-section shall not apply to any provisional order authorising a company or person to supply electricity so far as the order relates to any district in which the local authority is authorised to supply electricity; and (*b*) a provisional order authorising the breaking up of roads outside the area of supply, shall not be granted by the Board of Trade except with the consent of the local authority in whose district the road is situate, unless the Board of Trade, in any case in which the consent of any such local authority is refused, are of opinion that, having regard to all the circumstances of the case, such consent ought to be dispensed with, and in that case they shall make a special report stating the grounds upon which they have dispensed with such consent.

(2) The notice required by Section 4 of the Electric Lighting Act, 1882, to be given to a local authority on or before *the first day of July*, need not be given to the local authority of a district in which it is not intended to take power to distribute electricity.

*Clause* 7.—Makes five years the ordinary period for the revision of the maximum price on the demand of a reasonable number of consumers.

*Clause* 8.—Makes alteration in the 1899 Act respecting the certification of meters, and provides that "a meter shall be certified to be a correct meter within the meaning of any Act or provisional order relating to the supply of electricity passed or confirmed before the commencement of this Act, if it is capable of ascertaining the value of the supply within such limits of error as may, as respects meters of the class to which the meter belongs, be allowed by the Board of Trade."

*Clause* 9.—Deals with the dates for the making up of accounts of municipal undertakers. The dates selected are either March 31 or June 30, but these may be varied to meet special objections.

*Clause* 10.—*Supply of Electricity to Premises having Separate Supply*—Notwithstanding anything in the Electric Lighting Acts or in any Act of Parliament or provisional order authorising an undertaking, a person shall not be entitled to demand or to continue to receive from undertakers authorised to supply electricity in any area a supply of electricity for any premises having a separate supply, unless he has agreed with the undertakers to pay to them such minimum annual sum as will give them a reasonable return on the capital expenditure, and will cover other standing charges incurred by them in order to meet the possible maximum demand for those premises; the sum to be so paid shall be determined in default of agreement by arbitration under the Electric Lighting Act, 1882.

*Clause* 11.—Provides that undertakers may give or take a supply in bulk to or from any company or person.

*Clause* 12.—Protects gas undertakers from compulsory purchase of their land.

*Clause* 13.—Defines the terms used in the Bill.

*Clause* 14.—Makes the Bill applicable to Scotland and Ireland.

*Clause* 15.—Reads: (1) this Act may be cited as the Electric Lighting Act, 1905; (2) this Act and the Electric Lighting Acts shall be construed together as one Act, and may be cited as the Electric Lighting Acts, 1882 to 1905.

# LEGAL INTELLIGENCE.

## LYLES v. MAYOR AND CORPORATION OF SOUTHEND.

While the plaintiff was travelling on the outside of a car on Aug. 9, 1902, the connecting rod passing along the overhead wire broke and fell upon him, causing him severe injuries, and on March 31, 1903, he brought an action, claiming damages for injury "owing to the defective condition of the defendants' rolling stock." The defendants pleaded that if the injury complained of by the plaintiff had been caused through the act, neglect, or default of any of the defendants or their agents or servants, the same was done in pursuance or execution or intended execution of the provisions contained in the provisional order known as the Southend-on-Sea and District Light Railway Order, 1899 and of the defendants' public duty and authority, by virtue of which the defendants were working the tramways, and that the claim in the action was barred by reason of Section 1 of the Public Authorities Protection Act, 1893. That Act is entitled "An Act to generalise and amend certain statutory provisions for the protection of persons acting in the execution of statutory and other public duties." Section 1 is as follows: "Where after the commencement of this Act any action, prosecution, or other proceeding is commenced in the United Kingdom against any person for any act done in pursuance or execution or intended execution of any Act of Parliament, or of any public duty or authority or in respect of any alleged neglect or default in the execution of any such Act, duty, or authority the following provisions shall have effect, *inter alia*: (*a*) the action, prosecution, or proceeding shall not lie or be instituted unless it is commenced within six months next after the act, neglect, or default complained of, or, in case of a continuance of injury or damage, within six months next after the ceasing thereof." The question as to whether the defendants were exempted by that section from liability came on for trial as a point of law before Mr. Justice Bigham, who decided it in favour of the defendants. From that decision the plaintiff appealed.

After their Lordships had reviewed the case at great length, the appeal was dismissed.

## DAMAGES FOR COLLISION.

At Carlisle County Court last week John William Briggs sued the Carlisle Electric Tramways Company for £15. 15s., damages to his horse and trap caused by a collision with one of the company's cars. The approach of a tramcar made his horse restive, and the driver held up his hand and shouted to the motorman of the car to stop. The car still came on and the collision occurred. The motorman, in his evidence, said he could not see a hand at night at a distance of 20 yards, but he pulled up immediately he heard the shout. The Judge awarded the plaintiff £13. 13s., saying that the motorman did not stop as soon as he might have done.

## LIABILITY OF TELEPHONE SUBSCRIBERS.

At West Bromwich County Court the National Telephone Company sued Mr. H. J. Meredith, ironmonger, of High-street, Smethwick, to recover £5, the value of an instrument destroyed by fire.

**Mr. S. Vernon**, who appeared for the plaintiffs, explained that defendant, as a subscriber to the company, was supplied with an instrument under a contract. One of the conditions of the contract which defendant had signed was that the subscriber should be responsible for any damage to the company's apparatus whilst on his premises, and that in the event of it being destroyed by fire, or otherwise, the subscriber would pay £5 for each set of instruments as compensation

Judgment for the full amount claimed and costs.

## OBSTRUCTION.

Henry Sunderland was summoned at the Bradford City Court for wilfully obstructing a Corporation car.

**Mr. C. H. Bird**, assistant solicitor in the town clerk's department, said the seriousness of the offence would be realised when it was recalled that an accident recently occurred at that point. It was a very dangerous thing for the cars to have to stop there. The driver of the car rang his bell, and requested the defendant to move out of the way, but the cart was kept on the lines for five minutes.

The driver of the car said the man could easily have got out of the road either by crossing or turning up a side street.

The defence was that the driver of the cart was within his rights in retaining his position, and the case was dismissed.

# COMPANIES' MEETINGS AND REPORTS

## BROMLEY ELECTRIC LIGHT AND POWER.

The annual meeting of this Company (whose report we published in our issue of 31st ult.) was held at the Royal Bell Hotel, Bromley, last week, Mr. J. C. Wigham presiding.

The **Chairman** remarked that there had been a fairly uniform increase in the number of lamps. The directors held most strongly that an electric light company should put by the most substantial amounts it could afford for renewals in the time to come. They had, therefore, recommended that £300 more than that put by last year should be placed to the renewal reserve fund account, and they intended to keep on increasing this amount in the future.

A little discussion followed, and then the report was unanimously adopted.

Mr. E. Charrington and Mr. J. C. Wigham were re-elected directors.

Digitized by Google

## CALCUTTA TRAMWAYS.

The annual meeting of this Company was held on Tuesday under the presidency of Mr. E. C. Morgan, chairman of the Company.

In moving the adoption of the report and statement of accounts (of which we gave particulars last week), the **Chairman** said that the extensions to the power-house, station, plant, and buildings had been mainly in connection with the further power that would be required for the extensions in contemplation. Owing to the rapid extension of traffic, large additions had been made in the number of motor and trailer cars. That was an item on which further expenditure would shortly be needed. The proportion of expenses to income had been almost the same as in 1903—about 50 per cent.—which he thought the shareholders would agree was not unsatisfactory. The number of additional miles run, compared with the previous year, was comparatively small, being only about 8,000, but the running had been more scientifically adjusted. Consequently the earnings had increased by about ¾d. per mile. On the other hand, the running of thick services at the busy hours had naturally required the employment of more motormen, conductors, and other members of the staff, so that the expenses were also higher by ½d. per mile; but there had been an actual gain of ¼d. a car mile. Since the beginning of this year an agreement had been signed with the Howrah Municipality for the construction of a system of lines in that important district. It would probably be some little time before the necessary preliminaries were completed, but no time would be lost when the formalities had been complied with. They were also just completing an agreement with the municipality of Barnagore to construct a line into that northern suburb. Negotiations were well advanced for the extension of the lines to the south through Alipore to Behala.

The report was adopted.

## POTTERIES ELECTRIC TRACTION.

The annual meeting of this Company was held on Tuesday, Mr. G. F. M. Cornwallis-West presiding. Particulars of the report appeared in our last week's issue.

The **Chairman** remarked that, in spite of the dulness of trade, the results showed an advance on any previous year since the initiation of the Company. The increased items of expenditure were unavoidable, due to increased rates and insurance as well as to the running of an increased car mileage for the year—2,279,588 as compared with 2,081,964—an increase of 179,624 car miles. There had, however, been a distinct economy in working. The total expenses per car mile were 5·59d. as against 5·64d., and the expenses to receipts were reduced from 59 per cent. to 58 per cent. The receipts from parcels had increased. This traffic is engaging the attention of other tramway undertakers, and it is not improbable that a combination will be formed whereby the different owners will be able to act as each other's agents in the districts they respectively serve.

In all probability during the year some further capital will be required in connection with the construction of some of the light railways authorised by the Potteries Light Railways Extensions Order of 1902. An extension of time for this purpose has been granted by the Board of Trade, and after the successful completion of negotiations with the local authorities concerned, the Company has agreed to construct during this year short lengths of line at Handford, Sneyd Green, and Adderley Green, which they have every reason to believe will be remunerative.

The report was adopted.

## BABCOCK AND WILCOX.

The ordinary general meeting of this Company (whose report we published last week) was held on Tuesday at the Cannon-street Hotel, Mr. John Dewrance presiding.

The **Chairman**, reviewing the position, said that he regarded the profit for the year as abnormal, and hoped the shareholders would not put the onus on the directors if they failed to present such a favourable report again. Their business was an industrial concern, and while they had had an exceptionally good period of trade, they must be prepared to meet the effect of very heavy competition from other industrial concerns of a similar nature. Internal-combustion engines and various types of boilers were constantly being brought out. He considered the great results attained were largely due to the exertions of the management and staff. As some of the reserve fund, to which the directors proposed to add £175,000, formed part of their working capital, they had under consideration a proposal to transfer a considerable amount to the capital account. A scheme would be submitted to the shareholders at an extraordinary general meeting, to be called later, when he hoped they would accept the proposal.

**Sir William Arrol, M P.**, seconded the motion, which was carried unanimously.

## ANGLO-ARGENTINE TRAMWAYS.

The annual meeting of this Company (whose report we published last week) was held at Winchester House on Tuesday, Mr. J. B. Concanon presiding.

The **Chairman**, in moving the adoption of the report, said the Company had started the present year with £60,000 invested in first-class Stock Exchange securities, and it was the Board's intention to go on adding to both the reserve and the renewal funds. They had also inaugurated what was rather an innovation—a share redemption fund. Although the concession was for a long period, it had been deemed prudent to provide a sum sufficient to redeem the preference and the ordinary shares at the end of the concession. The item of £15,000 for paving might have been fairly charged to capital account, but the Board's policy had been, so far as possible, to restrict the capital outlay, and to provide for the cost of work of this class out of revenue. It was estimated that for this year and 1906 the amount which would be expended on paving would reach about £10,000 per annum. The Company took over the City of Buenos Ayres Tramways Company's system on Jan. 1 last, and the work of the electrification of the lines was begun almost at once, and was proceeding satisfactorily. A contract had been entered into whereby they would pay £650,000 in ordinary shares when the electrification of the city system was completed, and arrangements had been made for £400,000 of these shares to be offered to the ordinary shareholders of this Company at par, the contractors retaining the balance to dispose of as they thought fit. He also mentioned that the Board contemplated making an issue of a further £100,000 of share capital for the purposes of this Company.

The report was adopted.

## WINDSOR ELECTRICAL INSTALLATION.

The annual meeting of this Company was held at the registered offices last week, Mr. H. L. Prior, chairman, presiding.

The **Chairman** outlined the progress for the year, which is shown by the following figures: The number of lamps and motors installed on Dec. 31, 1903, was equivalent to 27,886 of 8 c.p. During the year 3,139 were added, bringing the total to 31,025 at the end of the year 1904, of which 2,362 represent the motor power. The revenue for the year from the lighting department was £11.484. 10s. 1d., and the total net profit, after providing £1,101. 12s. 8d. for interest on loans, was £4,485. 12s. 3d. The directors recommended that the sum of £1,000 be taken from the net profit and added to the depreciation, renewal and reserve fund, bringing that fund up to a total of £9,070. The balance available for distribution amongst the shareholders was £3,135. 12s. 3d., and the directors recommended that £200 be transferred from the dividend equalisation account to the net revenue, and that a dividend at the rate of 4½ per cent., less income tax, be declared, making a total dividend for the year of 7 per cent. The directors thought it desirable to apply for a provisional order for the area of Old Windsor and Clewer, but should there be any serious opposition, the question of going on with it may have to be considered. The Company's investment in the Slough and Datchet Company is £14,000, and the first dividend of 3 per cent. on this investment has been included in the net profit.

The report was unanimously adopted, as was a resolution authorising an increase of capital by the creation of £50,000 cumulative preference shares bearing 5 per cent. interest. It was only intended to raise £20,000 for the present.

## KIDDERMINSTER ELECTRIC LIGHTING AND TRACTION.

Mr. W. L. Madgen presided last week at the seventh ordinary general meeting of this Company, held in London.

In moving the adoption of the report and accounts, the **Chairman** explained that the Company had obtained an order authorising the construction of a light railway from Kidderminster to Bewdley similar to the line which ran between Kidderminster and Stourport. Unfortunately that line had to go through what was known as the Bull Ring at Kidderminster, and under the conditions prevailing the Company could not convey passengers through that section of the line. That meant a transference of the passengers from one car to another. The objection to that was fully realised by the Company, and every effort was made to induce the local council to give permission to take cars over that portion of the track with passengers, both in the interests of the public as well as in the interests of the Company. The Council, however, refused, and the Company had now given them notice that they did not intend to ask for an extension of the Board of Trade order. The costs incurred in the promotion of the scheme would be dealt with carefully. Recently the Company had made a satisfactory arrangement with the British Electric Traction Company by which the latter had taken over 27,500 of 4½ per cent. debenture stock at par. That had enabled them to settle certain liabilities, and had left them in easy financial circumstances. The Great Western Railway had commenced to run motorcars between Kidderminster and Stourport, but they did not apprehend that their traffic would be affected by such competition, if competition it could be called.

The report and accounts were adopted.

## INDO-EUROPEAN TELEGRAPH.

The report for the year ended Dec. 31 states that the agreements between the Postmaster-General, the Imperial German Post Office, and the Company for the leasing of land wires in this country and submarine cables between Lowestoft and the German coast, referred to in the last report of the directors, have been finally concluded. The retirement trust fund, constituted with the consent of the shareholders, has been duly established, and the amounts voted by the shareholders have been handed over to the trustees. The Company's revenue for the year from all sources amounts to £141,401, as compared with £139,094 for 1903, showing an increase of £2,306. The expenses are on commercial and general account, £47,876; and on maintenance account, £24,054—total, £71,930, as against £68,894 for 1903, an increase of £3,036. The revenue account shows a balance of £69,471, which is carried to profit and loss account, 1904. Bringing forward the balance of £16,356 from 1903, and deducting income tax paid and the interim dividend of £10,625, there remains an available balance of £71,267. The directors now propose to declare a dividend for the six months ended Dec. 31, 1904, of 17s. 6d. per share, making, with the interim dividend already paid, 6 per cent. for the year, and a bonus of 20s. per share, both tax free. They also propose to add £15,000 to the equalisation of dividends fund, and to hand over a further sum of £5,000 to the trustees of the retirement trust fund, carrying forward £19,392.

Digitized by Google

## FOLKESTONE ELECTRICITY SUPPLY.

The half-yearly meeting of this Company was held last week, Alderman Spurgen, the chairman, presiding.

The directors recommended a dividend at the rate of 7 per cent. for the half-year, making 5½ per cent. for the year. There was an increase of 10,110 lamps during the year, and that was the second best increase of any year of the Company's working. They now had 1,351 consumers, of whom 435 were taking the current by means of slot meters. A profit had been made out of the Hythe undertaking.

The report was adopted.

## BUENOS AYRES AND BELGRANO ELECTRIC TRAMWAYS.

At the annual meeting of this Company in London on the 6th inst. the **Chairman** said that the receipts last year showed an increase of £6,558 over the previous year. There had again been difficulty owing to the unreasonable demand of the employés, but this had been disposed of. The capital account showed an increase of £17,441, mostly due to the purchase of 15 new cars and to work done on the Nunez extension. They had provisionally applied for further extensions, representing about 4½ miles.

The report was adopted, and a dividend making a total of 4 per cent. for the 12 months was declared on the ordinary shares.

## URBAN ELECTRIC SUPPLY.

The annual meeting of the Urban Electric Supply Company, Limited, was held on the 6th inst. at the Westminster Palace Hotel.

**Mr. J. C. Wigham** presided, who said that the profits had increased from £13,822 to £21,020. The number of lamps connected had increased from 140,000 to 215,000, and a further 25,000 had been connected, or were awaiting connection, since the beginning of the current year. This year's revenue should show a proportionate improvement. The net profit was £19,437. Debenture and loan interest absorbed £5,101, and a loss of £134 occurred in realising a parcel of Consols. The amount required to pay the 5 per cent. guaranteed dividend on the preference and ordinary shares was £19,914, and the balance of £5,712 had been paid by Messrs. Edmundson under their contract. The capital expenditure had increased from £586,000 last year to £822,000. This had been incurred in the completion of their various stations. The capital expenditure in future, now that the works were fairly started, would be on a very much smaller scale. In regard to the legal difficulty as to the Company's right to supply to two districts of Weybridge and Walton from their Weybridge works, the Company's Bill in Parliament passed the third reading in the House of Commons on Wednesday night, and he did not think that the opposition would be carried on before the House of Lords.

The report was adopted.

## KALGOORLIE ELECTRIC TRAMWAYS.

The report for the six months ended Dec. 31 states that the profits (subject only to London expenses) are at the rate of £18,388 per annum, and this notwithstanding the facts that neither the Boulder line nor the racecourse extensions, nor the duplication of the Federal road (the main connection between Kalgoorlie and Boulder), were completed until a few weeks ago. It has been somewhat difficult to apportion the receipts and expenditure as between capital and revenue, and the course has been adopted of crediting all receipts and debiting all expenses to capital prior to June 30. In addition to the sum of £9,755, transferred from operating account to credit of capital account, the sum of £4,359, being the balance at credit of profit and loss account at Dec. 31, has been transferred to credit of capital account.

## CUBA SUBMARINE TELEGRAPH.

The report for the half-year ended Dec. 31 last, to be presented at the meeting on the 19th inst., states that the total receipts of the six months have been £13,815, while expenses amounted to £8,368, leaving a balance of £5,446, to which has to be added £4,647 brought forward from last account, giving a total of £10,093 to be dealt with. The directors recommend a dividend at the rate of 5 per cent. per annum on the ordinary shares, carrying forward £3 093. The new cable contracted for with Hooper's Telegraph and Indiarubber Works was duly laid between Cienfuegos and Santiago de Cuba, and was taken over on Feb. 18 in perfect condition. The Cape Cruz Santiago cable has since been repaired, and is now in good working order. The Cuban Government having refused payment of the subsidy for the coast cables, the Company's agent in Havana has been instructed to appeal to the courts against the President's decision. The claim against the United States Government for payment of the cost of repairing the damage done to the cables during the Spanish-American war is still unsettled.

## BARCELONA TRAMWAYS.

The report for the year 1904 states that the traffic receipts show an increase over 1903 of £15,400, and the working expenses an increase of £1,333. The balance at credit of revenue account for 1904, after adding £3,940 received from the Enschenche Company, and the £1,501 from the previous account, is £46,232. Of this sum the interest and sinking funds of the debentures and of the debenture stock have absorbed £16,600; interest on loans, £723; and the dividend on preferred shares, £5,000. The directors have placed a further sum of £10,000 to renewal fund, raising it to £17,000, and they recommend a dividend on the ordinary shares at the rate of 6 per cent. per annum (12s. per share), free of tax, and that the sum of £2,527 be carried forward to next account.

## BRITISH ALUMINIUM.

The annual report of this Company states that the profit for the year 1904 is £55,411. 3s. 11d. From this has to be deducted the debit balance of £3,837. 17s. 10d. brought forward from 1903, and debenture stock interest £15,000, leaving £36,573. 6s. 1d. Out of this £3,949. 10s. 9d. has to be set aside for the redemption, with interest, of the deferred commission warrants issued in 1901, leaving an available balance of £32,623. 15s. 4d. One-fourth of this amount will be applied in accordance with the debenture stock supplemental trust deed in redeeming and cancelling £8,000 of the debenture stock, and out of the balance the Board proposes to apply £10,169 in payment of arrears of dividend on the A preference shares, £11,983 in payment of a dividend of 6 per cent. on the A preference shares for the two years 1903-1904, £1,500 in payment of a dividend at the rate of 7 per cent. on the 7 per cent. preference shares, and £700 in payment of a dividend of 7 per cent. for the year 1904 upon the ordinary shares, leaving a balance of £114. 16s. 5d. to be carried forward. The Company's interest in the Loch Leven power scheme has been transferred to the Loch Leven Water and Electric Power Company, as that company must carry out the works under the terms of the Loch Leven Water Power Act. To provide for the cost 50,000 shares of £10 each, part of its capital, will be issued. These will all be subscribed by this Company, which will thus own the whole of the issued capital of the Loch Leven Water and Electric Power Company.

## CONTRACTS FOR ELECTRICAL SUPPLIES.

**Govan.**—The Council require annual stores. Tenders by 25th inst.

**Portsmouth.**—The Council require annual stores for tramways. Tenders by May 1.

**Edinburgh.**—The Corporation invite tenders for water-tube boilers. Tenders by May 8. See advertisement.

**Dublin.**—The Port and Docks Board invite tenders for an electric generating station. Tenders by May 15.

**Wallasey.**—The Council require annual supply of stores for their electricity works. Tenders by 27th inst.

**Cartagena.**—The Public Works Department, Madrid, require tenders for electrification of the local tramways.

**Erith (Kent).**—The Urban District Council invite tenders for the wiring of their car depôt and workshops. Tenders by April 17.

**Kingston-upon-Hull.**—The Council invite tenders for air-space telephone cable. Tenders by 17th inst. See advertisement last issue.

**Swindon.**—The Corporation invite tenders for the supply of electric motors for a period of three years. Tenders by April 17. See advertisement.

**Stockport.**—The Gas and Electricity Committee invite tenders for the supply of one 500-kw. steam generator. Tenders by April 26. See advertisement.

**Bournemouth.**—The Town Council invite tenders for steel poles, overhead line, section boxes, etc., for the tramways. Tenders by 10 a.m. on April 20.

**Woolwich.**—The Guardians invite tenders for wiring the union infirmary and nurses' home for electricity, and supplying fittings. Tenders by 4 p.m. on 19th inst.

**Liria.**—The Municipality require tenders for installation of electric lighting; 2,000 c.p. are required for street-lighting, for which it is proposed to pay 6,000 pesetas per annum.

**French West Africa.**—The Governor-General of French West Africa, at Dakar, requires tenders for the erection and equipment of a central station at that place. Tenders by May 15.

**Devonport.**—The Electricity Department invite tenders for the supply of one surface condenser with electrically-driven pumps. Tenders by April 18. See advertisement in last issue.

**Fulham.**—The Council invite tenders for condenser piping, sump and river work, steel roof and bunker work, and coal-conveying apparatus. Tenders by 25th inst. See advertisement.

**Bilbao.**—The Public Works Department at Madrid require tenders for the concession of an electric tramway in Bilbao, from the Calle de Hurtado de Amézaga to Plaza Circular. Tenders by April 24.

**Laventhem (Belgium).**—The Municipality require tenders for erection of central station, laying of mains, etc. Particulars (3s. 4d.) may be obtained from the Secretary of the Mayor of that place.

**Glasgow.**—The Corporation invite tenders for the supply of (1) main cables, (2) electricity meters, and (3) carbons for a period of 12 months from 31st prox. Tenders by April 17. See advertisement in last issue.

**Antwerp.**—Tenders will shortly be invited by the Belgian State Railways for the installation of electric light in their local railway station. Specification No. 619 may be obtained from the Government Railways Office, Brussels.

**Bristol.**—The Docks Committee invite tenders for the construction, delivery, erecting in place, fitting, testing, and maintenance for 12 months after completion of two electric goods lifts and one electric passenger lift. Tenders by May 1.

**Wimbledon.**—The Urban District Council invite tenders for the supply and erection of a 1,000-kw. steam-driven turbo-alternator, with condensing plant, high-tension switchgear, and pipework. Tenders by April 28. See advertisement in last issue.

Digitized by Google

**New Ferry (Cheshire).**—The Lower Bebington Urban District Council invite tenders for the work of electric installation for fire brigade alarm in New Ferry, and also for supply of street lanterns for incandescent lighting. Tenders by April 24.

**Glasgow.**—The Trustees of the Clyde Navigation invite tenders for electric power generating and lighting plant for Clydebank Dock. Specifications, etc., may be obtained from Mr. T. R. Mackenzie, 16, Robertson-street, Glasgow. Tenders by April 17.

**Batley.**—The Corporation invite tenders for tramway extensions—viz.: (Contract No. 14) permanent-way construction and paving; (15) overhead equipment, steel poles, etc.; (16) feeder cables, conduits, and accessories. Tenders to the Town Clerk by April 17.

**Cardiff.**—The Corporation invite tenders for the following plant for their power station on the extra high-tension system: extra high-tension three-phase main switchboard for power station; switchboards for sub-stations; motor-generators; rotary converters, etc. Tenders by April 17.

**Switzerland.**—M. R. Vontobel, of Winterthour, and M. Charles Probst, of Lucerne, have obtained a concession for the construction of a narrow-gauge electric railway from Meiringen to Gletsch. The total cost of the enterprise is estimated at £241,600; £19,600 is to be expended on rolling-stock.

**Wigan.**—The Corporation invite tenders for steam dynamo and accessories; steam and water piping, ejector condenser, and motor-driven centrifugal pump; paper and lead-covered cables; dry-core telephone cables; paper and lead-covered cables (twin service), and vulcanised rubber cables. Tenders by 17th inst. See advertisement last issue.

## RESULTS OF TENDERS.

**Battersea.**—The Council have ordered from Parsons and Co. a spare armature for No. 6 machine at £573.

**Leith.**—The Corporation have placed the contract for a traction switchboard with Ferranti Limited, Hollinwood, Lancashire.

**Bury.**—The Corporation have, we understand, accepted the tender of Wilson and Stockhall, Bury, at £82. 10s. each, for six tops to tramcars.

**Lowestoft.**—The Town Council have accepted the tender of Babcock and Wilcox, at £1,337, for providing the new boiler, with superheater, brickwork, settings, and accessories.

**Salford.**—The Corporation have awarded R. J. Nicholson and Co., of Manchester, the contract for the electric lighting of the Seedley Schools, together with the supply of the necessary fittings.

**Halifax.**—The Town Council have accepted the tender of E. Allen and Co., Sheffield, at £730, for the supply and erection of two 20in. belt conveyors for the proposed coal siding and coal stores at the electricity works.

**Ashton-under-Lyne.**—The Electricity Committee have accepted the tender of G. R. Mather and Son, Albion Foundry, Wellingborough, for the supply and delivery of a deep-well pump for their electricity works.

**Swindon.**—The Council have accepted the following tenders for the electricity works: Siemens Bros., at £46. 8s. 6d. each, rewinding armatures of motor-generator; Bennis Stoker Company, Bolton, £127. 10s., new boiler; W. and T. Avery, £70, 10-ton weighbridge, 12ft. by 8ft.

**Fulham.**—The following tenders have been received:

Condensing plant.

| | 28in. vacuum. | 26in. vacuum. |

The accepted tenders appeared in our last issue.

**Yarmouth.**—The Council have accepted the following tenders: Willans and Robinson, at £2 358, for engines, with Mather and Platt alternator; Babcock and Wilcox, £1.500, boiler; G. and J. Weir, £1,400, condensing plant; British Insulated and Helsby Cables, £911. 17s. 10d., extension cable.

**Bradford.**—The Electricity Committee have decided to recommend the acceptance of the tender of the British Westinghouse Company for the generators, and that of the General Electric Company for the switchgear in connection with the adoption of the three-phase system. The tenders total £10,000.

**Condensing Plant.**—The Worthington Pump Company, Limited, Queen Victoria-street, London, E.C., record the following condensing business secured during the last month: one complete condensing set, to deal with 20,000lb. of steam, for the Fulham Electric Light Station; three combined condensing sets, each to deal with 10,000lb. of steam per hour, for Messrs. Lever Bros., Port Sunlight; one condensing set, being a repeat order, for the Malta Dockyard; one condensing set for the Leeds Forge Company, and an experimental set for the Heriot-Watt College, Edinburgh; one complete condensing set for Milan Electric Light Station; one winch condenser, for marine service, for the North-Eastern Marine Company; one horizontal jet condensing set, for use with Ratean turbine, for the Hucknall Torkard Colliery; one barometric condensing set for South Wales; three oil separators, each to deal with 20,000lb. of steam, for the Belfast Tramways, this being a repeat order; one separator for Pekin Electric Light Station, and number of other separators for various jobs; two cooling towers for Bradford Mills; one large water-softening plant for a Durham Colliery.

# BUSINESS NOTES.

## TRACTION.

**Southend.**—During March 278,548 passengers were carried on the tramways, the fares amounting to £1,071.

**West Cumberland Tramways.**—This Bill, which seeks a further extension of time, has passed the House of Lords.

**Exeter.**—The tramways' takings for the third day amounted to over £39, and the number of passengers carried was 9,545.

**Scarborough.**—The company have ordered five new cars for the coming summer season. They will then have 22 running.

**Bury.**—The Corporation have decided to provide covered cars, and have just placed an order for six of these covers with Messrs. Wilson and Stockall, the well-known ambulance makers, of Bury.

**Rangoon.**—The construction of this electric tramway is reported to be proceeding apace, and it is probable that Messrs. Darwood and Co. will complete the undertaking in the course of the present year.

**Sweden.**—The *Journal de St. Pétersbourg* states that the Swedish State Railways Department are about to submit a project to the Riksdag for the purchase of the waterfalls near the principal lines.

**Tynemouth.**—The Tynemouth District Electric Traction Company were successful last week in their appeal to the Northumberland Quarter Sessions, securing a reduction of the assessment of their undertaking from £1,800 to £1,367.

**Bournemouth.**—At a meeting of the Town Council last week the borough surveyor submitted alternative proposals for the linking of the lines connecting the Bournemouth and Poole tramways. The plans were approved, and the surveyor instructed to proceed with the work.

**Metropolitan Electric Tramways.**—The revenue account for 1904 shows a surplus of £32,283. Allowing for preference interest and repayment to British Electric Traction Company of balance due to them for advance made in January, 1903, £3,854 is left, which amount is carried forward.

**Switzerland.**—The *Feuille Féderale Suisse* publishes a decree granting a company, headed by M. Francesco Balli, mayor of Locarno, a concession for the construction and working of an electric tramway from Locarno to Lake Maggiore and Minusio. The tramway will eventually be carried to Gordola.

**Kirkcaldy.**—At the monthly meeting of the Town Council on Monday a minute of the Tramway Committee was submitted making certain recommendations regarding the tramways, including one that no extension be made at present either in the Links district or to Dysart. Eventually the recommendation was approved.

**Heywood.**—As the result of a conversation between members of the Heywood and Bury Corporations it is reported that terms may now be agreed for the working of the former's trams by Bury. The Tramway Committee of the latter authority view the suggested arrangement with favour, and the decision of the Heywood Council is awaited.

**Hastings.**—Terms have been agreed between the Corporation and the company, under which the Upper Church-road line will be abandoned, and other outstanding points of a minor character have also been settled. The proposed feeder system for supplying the energy to operate the cars has been approved by the Corporation.

**Leeds.**—It is reported that terms will probably be arranged shortly between the Corporation and the Calverley Urban District Council for linking up the two towns. The Urban District Council obtained a tramway order 12 months ago. The extension to Rodney is being rapidly pushed forward, and a portion of it will be opened in a few days.

**York.**—The secretary of the company writes to the local Press stating that the company were quite prepared, and indeed anxious, to undertake the electrification of the system themselves, but that, as the parties failed to come to terms, the Corporation are placing obstacles in their way by refusing their consent to the work of reconstruction.

Digitized by Google

**Dundee.**—The Town Council last week again considered the question of running Sunday cars, against which the citizens decided by a *plébiscite* two years ago. Mr. Brownlee moved that they be given three months' trial, and, on a division, 14 voted for and 14 against. Lord Provost Barrie gave his casting vote against Sunday cars, which were therefore vetoed.

**Edinburgh.**—At a meeting of the Linlithgow District Committee plans were submitted of the proposed Edinburgh and Queensferry tramways, as also a notice that application was intended to be made by the National Electric Construction Company for a provisional order for the construction of the tramways. The meeting unanimously agreed to lodge objections to the granting of the order.

**Spain.**—The *Gaceta* publishes a decree authorising the Société des Tramways de Grenade et de Murcie to substitute electric for animal traction on the tramway from Murcia to Alcantarilla and Espinardo. No higher tender having been received for a concession for an electric tramway between Azcoitia and Zumaya, in the province of Guipúzcoa, than that of Don Dionisio Sorseta Garcia, the concession has been granted to that gentleman.

**Rochdale.**—The reconstruction of the section between Sudden and the Heywood boundary has been completed. The other routes are being pressed forward with all expedition. It has been decided to defer the question of issuing contract tickets. Including the parcels traffic the receipts on the electrically-equipped sections during March amounted to £1,941. 4s. 7d., against £1,602. 19s. 11d. in February, and £1,718. 18s. 4d. in January.

**Swansea.**—At a meeting of the Tramways Committee, the suggestion of the company that the Corporation should supply them with power at ½d. per unit till the whole system was completed, and then institute the agreed scale, was not favoured by the committee, and it is probable that the point will be submitted to the Board of Trade for arbitration. It has been decided to make urgent representations to the Harbour Trust to complete the North Dock bridge in order that the extension may be opened at an early date.

**Chile.**—The *Chilian Times* reports the passage of a Bill through the Senate granting permission for the construction of an electric railway, which, starting from the port of Valparaiso, will pass through the Casablanca and Curacavi Valleys and communicate with Santiago by the west, having a branch line connecting the Curacavi Valley with the town of Nelipilla. The length from Valparaiso to Santiago will be about 89 miles. All the materials, implements, and machinery imported for the construction and exploitation of this line are to be free of customs duties.

**Municipalisation in the States.**—Chicago having decided upon the municipalisation of the tramways, requested the Glasgow Corporation to lend assistance by placing an expert at their disposal in the work of transferring the system from private to public ownership. Glasgow has given an affirmative reply, at which Judge Dunne, the newly-elected mayor, has expressed his gratification. He says that he believes scores of American cities will follow the example of Chicago. It is reported that Judge Dunne intends to make visits to several eastern cities, including New York, in order to begin agitations for the purchase of the local tramways by the various corporations.

**Llanelly.**—The purchase of the tramways has been completed. Mr. Howell, solicitor, and Mr. David Evans, representing the vendor company, attended at the offices of the London agents (Messrs. T. D. Jones and Co.), where they met the representatives of the new company, and an assignment having been executed, the amount of purchase money and all claims was paid in accordance with the arrangement. News of the completion of the purchase was received in Llanelly on Friday night with general satisfaction. It is expected that the present antiquated service will before long be replaced by an electric system, for which application is to be made to the Light Railway Commissioners, as the order granted by them has lapsed.

**Leicester.**—As a car was going underneath the Great Central Railway bridge into Dun's-lane on Monday, the trolley left the wire and got fast in the overhead work. The pull broke the wire at a point which was just outside the bridge and on a curve. The wire fell first on the car and then on the ground, but by the automatic device fitted to the Leicester system the electric current was cut off immediately it touched the ground. A few sparks were emitted by the wire when it touched the car, and also when it struck the ground, but there was no danger to anyone. The officials at the power station were at once telephoned to, and in a very short time the repair van was on the spot, and within half an hour the cars were running again.

**Central London Railway.**—A fire occurred at Notting Hill Gate Station at a quarter to six on Tuesday evening. It appears that the fire broke out in the sub-station, the wires in the distributing box fusing. A quantity of smoke rolled out into the station, tunnels, and lifts, creating some consternation among the passengers. The smoke found an outlet into the street through the air shafts. A constable promptly summoned the fire brigade, and in the meantime the station staff, thoroughly equipped in cases of fire, got a hydrant to work, and also employed sand to smother the outbreak. It was found necessary to cut off the current throughout the entire line, and for an hour and a half no trains were running. The distributing box being constructed entirely of stonework prevented the fire from spreading to other parts of the station.

**Stalybridge, etc., Board.**—The Stalybridge, Hyde, Mossley, and Dukinfield Joint Board has approved the following resolution of the Tramway Committee: "That a communication be forwarded to the Oldham, Ashton, and Hyde Electricity Company, Limited, asking for an appointment to meet representatives from the Board to consider whether it would be possible to arrange for running powers between Newton-street and the Market-place, Hyde; that a sub-committee, consisting of the chairman and deputy-chairman of this committee, the chairman of the Board, and Messrs. Oldham and Kenny, be appointed to meet the representatives of the company; and that as an alternative arrangement, a loop with movable points at each end be laid about the centre of George-street." Further cars have been ordered from the British Westinghouse Company.

**Ashton.**—The example of Manchester in instituting an elaborate goods service seems likely to be followed by their neighbours at Ashton. The Corporation has a scheme under consideration, drawn up by the tramways manager (Mr. A. Covaney), by which it is sought to develop and increase the earning capacity of the tramways of the borough, and possibly obtain inter-running with other authorities in time to come. For a long time it has been thought that a still greater use might be found for the tramways than simply carrying passengers, and ways and means have been devised for increasing their earning capacity by the carriage of coal, cotton, and merchandise. No definite arrangements have, however, been made, and investigations are being carried on by the Tramway Committee with a view to evolving a practical scheme. It is in the carriage of coal that the manager sees prospects of a profitable return on the outlay which would be necessary to carry out the scheme satisfactorily.

**Croydon.**—The Corporation's Bill for power to construct certain tramways, to run a service of motor omnibuses, and to supply electricity in bulk outside the district came before a committee of the House of Commons in the early part of the week. The committee, in giving their decision, said it was only in the case of thoroughly well-considered and thought-out schemes that such powers could be given, and as in this case they did not consider that the scheme had been well thought out, they must strike out the omnibus clause. The clause giving the Corporation power to supply electric light in bulk outside their area was agreed to. Interesting statistics have been compiled regarding the tramways, which since the electrification have been worked under lease from the Corporation by the British Electric Traction Company, Limited. During the last three years of the old horse cars 10,000,000 passengers were carried, but during the three years of the electrified system 40,000,000 have been carried. In the last 12 months the population of Croydon, about 145,000, has been carried almost 100 times over.

**South Shields.**—At the meeting of the Town Council, the consideration of tenders in connection with the electric tramways was proceeded with. After proposals to delete three routes had been rejected, Councillor Grant moved that the tender of Messrs. Hurst, Nelson, and Co., Limited, for 10 electric cars at £5,307 be accepted. Councillor J. W. Henderson seconded, and remarked that the portion of the trucks which was of American manufacture was only 8 per cent. of the total value. Councillor R. D. Barlow was strongly opposed to the Corporation adopting the Brill truck, and maintained that they could obtain equally as good a truck of British manufacture. The British manufacturers, he complained, had not had a chance of tendering for the cars, because it was specified that the trucks were to be of the Brill type, which meant that they were to be made in America. He thought the British manufacturers should be treated fairly, and in support of the British-made truck he quoted several instances to show that they were being adopted in connection with important systems throughout the country. He moved that the subject be referred back to committee, and this was carried.

**Aberdare.**—The Urban District Council's Bill for tramway and other purposes was proceeded with by a Select Committee of the House of Commons last week. Mr. Noble, addressing the committee on behalf of the Taff Vale Railway Company, submitted that the way in which the railway company was affected by the scheme entitled them to peculiar consideration. If the scheme did not prove a financial success, not only would the railway company be injured by losing their traffic, but would have to contribute to the loss on the scheme out of the increased rates. The evidence clearly showed that there could be no steady demand for tramway accommodation during the whole of the day, and he suggested that the 10-minute service on which the promoters relied could not be justified. After making proper deductions, he estimated a loss on the trams of £1,790 for 30 years. He called attention to the decrease in the output of coal since 1894, showing that the rateable value of the district was not likely to increase. He asked the committee to say that the Bill should not be proceeded with. Mr. Wedderburn, replying for the promoters, contended that the case as to competition set up by the Taff Vale Railway Company had broken down. The Powell Duffryn Company, Lord Bute, and the Cwmaman Coal Company paid one-third of the rates, whereas the Taff Vale Company paid an extremely small amount. He met the declaration that the district was decaying by pointing to the statement before the Royal Commission that there was enough coal in the district to last for 80 years, and to another calculation that the supply would last for at least 100 years. The great majority of the people strongly desired the tramways. Having regard to the present satisfactory position of Aberdare, he submitted that the tramways would not throw an undue burden on the rates. Striking a margin between the estimates presented, he put the loss on the tramways at £446 a year. The Chairman announced that the committee found the preamble of the Bill proved except in respect of the tramways.

**Belfast.**—At a meeting of the Tramways Committee on Monday a report by Mr. Nance, the general manager, on the question of fares was considered. Ultimately it was decided to allow the publication of the report before coming to any conclusion, in order that the question might be fully discussed, and that the committee might thus have the advantage of ascertaining the views of the citizens generally. The report, which is a lengthy document, states, that in his opinion, there are four systems of fare which are applicable to the special conditions of the Belfast tramway system: (*a*) universal 1d. fare; (*b*) the present scale of fares; (*c*) 1d. from Castle Junction out; (*d*) ½d. fares. He proceeds to consider these seriatim, dwelling at greatest length upon the first, which he favours most. No other fare would be taken on the tramcars except a 1d. fare, with the exception of the children's ½d. fares, which would be available on

Digitized by Google

the same conditions as at present. He points out that the machinery of collecting and accounting for the receipts of the undertaking would by this system be simplicity itself, and it would also be extremely easy for citizens and visitors to understand. In support of the system, he instances the case of Hull, with a population of 250,000, where ever since the tramways were first worked by the Corporation six years ago a universal 1d. fare has been adopted, with very favourable results. Mr. Nance believes that by this system a balance of £45,000 in relief of rates can be reached in the second year of working under normal conditions. As to maintaining the present scale of fares, Mr. Nance gives as a primary objection the fact that the citizens have expected a material reduction, and will be disappointed if it is not granted. The present fares would, he believes, leave an annual sum available for the relief of rates of £25,000 within two years. As to the third system, this would result in a great part, if not all, of the 2d. fares being turned into 1d. fares, and Mr. Nance does not believe much of this loss would come back. There would also have to be a number of overlapping stages—so lengthened that he doubts if it would be possible to make both ends meet. In fact, if stages are to be retained at all, he considers it would be far better to retain the present stages. As to the fourth system, he is of opinion that the adoption of ½d. fares would mean that the undertaking would be worked at a considerable loss. He therefore sums up strongly in favour of a universal 1d. fare.

**London County Council.**—The most important matter in the Highways section of the agenda for Tuesday's meeting referred to the Council's northern system, leased to the North Metropolitan Tramways Company. The Highways Committee have from time to time submitted to the Council reports dealing with the reconstruction for electrical traction of this division, and they have now prepared a further report, in which they state that it appears to them to be so important for the whole question to be dealt with at once, that they are submitting for the Council's consideration the proposed terms of an agreement with the company (who work the lines under a lease which expires in 1910) for the surrender to the Council upon agreed terms as from April 1 next of the remaining portion of their lease. Some time ago the committee came to the conclusion that the difficulties in the way of arranging for the reconstruction of the tramways under the provisions of the lease were so serious as to indicate that the only satisfactory manner in which this work could be carried out efficiently and expeditiously would be for the Council itself to obtain possession of the lines. Negotiations were accordingly opened with the company, which have resulted in certain terms being arranged. The company has expressed its willingness to sell its interest in the lease to the Council as from April 1 next for £120,000. Further, the Council agree at the same date to purchase from the company for £315,000 the company's rolling-stock, horses, and plant. If the transfer of the tramways to the Council is arranged as proposed, it is hoped that it will be possible to make the necessary arrangements to proceed immediately after the acquisition with the electrification of the lines. Even if the sacrifice of the profits secured to the Council under the lease entailed some financial loss (which, however, the committee do not think in the long run would be the case) they are still of opinion that the course now proposed would be justified to secure to North London the benefit of electric tramways four years sooner than would otherwise be possible. No estimate has yet been made of the expenditure involved in the scheme for electrifying the northern tramways; but approximately it will be £3,000,000 for tramway works, and £1,000,000 to £1,500,000 for street widenings, or a total of £4,500,000, which will in all probability be expended at the rate of about £1,000,000 a year. About one-half of the lines will, as at present proposed, be reconstructed on the underground conduit system and the other half on the overhead trolley system. It is estimated that the annual mileage run on the northern lines will be 21,024,000, and that the profit on working, at 5d. a car mile (which the committee do not consider an excessive figure), would amount to £438,000 a year. If provision for renewals be made at the rate of 1d. per car mile, £87,600 would have to be deducted from the estimated profit, leaving a balance of £350,400. The interest and repayment charges which would have to be made amount to £252,500 a year, leaving a balance of £87,000. These figures exclude the question of street widenings. The Council are also to be entitled to purchase in 1910 the portion of the tramways not included in the company's lease. As the amount involved exceeds £5,000, consideration of the matter was adjourned for a week in accordance with the standing order. The tramways in Camberwell New-road and Church-street, Camberwell, have been linked up, and a short junction line has also been constructed from Camberwell New-road to the authorised tramways in Denmark-hill. Through services have been instituted between Greenwich and certain of the London termini, *via* Camberwell New-road, materially assisting in the relief of the traffic along congested routes. The undertaking of the Woolwich and South-East London Tramway Company will be taken over by the Council on May 31. The Council have voted the £26,000 (referred to in our last week's issue) for diversion of mains along the Wandsworth and Battersea routes, and have decided to call for tenders for the construction of the tramway in Archway-road, Highgate. Mr. J. W. Benn addressed to the Press the other day a spirited reply to the letter of Sir Joseph Dimsdale against trams along the Embankment. Mr. Benn, after dealing with the various statements made by Sir Joseph, deprecates the expression of hostile opinions pending the report of the London Traffic Commission. The Council have come to an arrangement with the Middlesex County Council under which the Council will construct, at their own expense, a line of three furlongs in the Islington area to link up the Archway-road and Archway Tavern trams of the Middlesex Council. The line will be leased to the lessee company for three years, at a rental of £1,500 for the first, £2,000 for the second, and £2,500 for the third year. The company will pay to the Middlesex County Council a percentage on the takings of this line as they are to do with the lines in the county of Middlesex. When this line is completed cars will run from the Archway Tavern to Whetstone direct. A general meeting of the London, Deptford, and Greenwich Tramway Company was held last week, when the Chairman stated that, owing to the expense involved, the company decided not to appeal to the House of Lords in respect of the additional sum of £22,773 provisionally awarded them by the arbitrator on the transfer of their undertaking to the Council, but disallowed by the Court of Appeal. The liquidation of the company will take about 12 months.

## LIGHTING AND GENERAL.

**Grimsby.**—The Council have decided to borrow £3,000 for electric lighting purposes.

**Islington.**—The report mentioned in our last issue will again come before the Council to-night.

**Walsall.**—The Electricity Committee are about to expend £1,350 in providing an additional supply of current for the centre of the town.

**Swansea.**—The Sub-Electric Lighting Committee have insured the electric light works in the County Fire Office for the sum of £30,000.

**Sale of Plant.**—Particulars of a sale of an electrical engineer's stock in-trade by Messrs. Scottorn and Smedley appear in another column.

**"Eltradion."**—Under this title the Electrical Trades Union have published No. 1 of their official organ. It appears to be in favour of the London County Council Wiring Bill.

**Burnley.**—The Council have decided to purchase a new steam generator of 500 kw. for the electricity works, and to apply for sanction to the borrowing of £6,015 to meet the cost.

**Direct United States Cable Co.**—An interim dividend of 3s. per share, tax free (being at the rate of 3 per cent. per annum), for the quarter ended March 31 is payable on the 25th inst.

**Elland.**—The total output from Feb. 1 to 28 was 8,832 units, being a decrease of 3,094 units on the previous month, and an increase of 5 889 units on the corresponding period of last year. A new cable is to be laid.

**Calendars.**—We have received a belated calendar issued by Messrs. Parmiter, Hope, and Co., Hulme Electrical Works, Manchester, 74, York-street, Glasgow, makers of switchboards, arc and incandescent lamps, and accessories.

**Battersea.**—It has been decided to connect up the network of electric mains in the neighbourhoods of Albert Bridge-road, Bridge-road, Bridge-road West, Bolingbroke-road, Church-road, Park-road, Northcote-road, Morella-road, Rusham-road, Sudbrooke-road, and Old Park-avenue, so as to secure more efficiency in the supply of electrical energy, at an estimated cost of £800.

**New Issues.**—We note the following new issues: The County of Durham Electrical Power, 30,000 preference shares of £5 each and £40,000 ordinary shares of £5; the Montreal Light, Heat, and Power Company, 7,500 shares of 100dol. each—750,000dol.—in certificates of five and ten shares each; Yorkshire (West Riding) Electric Tramways Company, Limited, £275,000 4½ per cent. first debenture stock (part of a total authorised issue of £400,000). Full particulars appeared in our last issue.

**Widnes and Runcorn Transporter Scheme.**—A special generating station has been built on the Widnes side of the Mersey to supply the power for the transporter in course of erection for the company, of which Sir John Brunner, M.P., and Sir Henry Seton-Kerr, M.P., are the chairman and vice-chairman respectively. The contractors for the various works are: Arrol's Bridge Company, Glasgow; St. Helens Cable Company; Messrs. Holme and King, Liverpool. The engineers are Messrs. John J. Webster, Westminster, and John T. Wood, Liverpool. Mr. C. H. Chase is the resident engineer.

**Eastbourne.**—At an interview of the representatives of the Town Council and the Eastbourne Gas Company with the Hon. T. H. W. Pelham at the Board of Trade on Wednesday, the extension of the electric lighting system to Willingdon was discussed. It resulted in the Corporation agreeing to leave the question of the insertion of the Northumberland clause in the new order and also in the old order to the Board of Trade, and to abide by their decision. The gas company consented to this course, but reserved their right to prosecute the matter before the House of Lords Committee.

**Opening of Streets.**—At the Court of Common Council on Thursday a letter was read from the Metropolitan Paving Committee stating that they had decided to convene a conference of representatives of the City Corporation, the Westminster City Council, and the Metropolitan Borough Councils, to be held at the Westminster City Hall, Charing Cross-road, on Friday, May 19, at 5 p.m., to consider the question of the opening of streets by public companies and others, and asking the Corporation to appoint two representatives, with the town clerk and engineer, to attend such conference. The matter was referred to the Streets Committee, with power to appoint two representatives.

**Stock Exchange.**—The Stock Exchange Committee have ordered the undermentioned securities to be quoted in the official list: Baker-street and Waterloo Railway Company—Speyer Bros.' scrip certificates to bearer (partly paid) for £500,000 4 per cent. perpetual debenture stock; and Folkestone Electricity Supply Company's 10,000 5 per cent. cumulative preference shares of £5 each fully paid, Nos. 1 to 10,000. Applications have been made to the committee to allow the following securities to be quoted in the official list: Sao Paulo Tramways, Light, and Power Company's 70,000 shares of 100dol. each, and 5 500,000dol. 5 per cent. 30-year gold bonds of 500dol. each; and South Metropolitan Electric Light and Power Company's further issue of 85,368 7 per cent. cumulative preference shares of £1 each, fully paid, and 4½ per cent. first debenture stock.

Digitized by Google

**Acton.**—The electricity works have closely approached completion. The arc lamps in the street have been lighted temporarily. A good many house connections have been made, and current is being supplied experimentally.

**County of London Electric Supply Co.**—We are informed that the Holborn and Finsbury electrical exhibition, which closed its doors on Wednesday last week, was visited by nearly 50,000 people during the short run of its existence.

**Thornhill.**—The Yorkshire Electric Power Company have offered to instal 160 20-c.p. lamps on 80 trolley poles at a total cost of £192 per annum, or £2. 8s. per lamp-post. Trial lamps are to be erected at Savile Town and at Thornhill Lees.

**Windsor**—The Windsor Electric Lighting Company have declared a dividend of 7 per cent. Last year it was 8 per cent. The public street-lighting has been doubled without any appreciable extra charge, and there is a decreased charge to private consumers.

**Electric Lighting of Ferry Steamers.**—An estimate for lighting the East Indian Railway ferry steamers "Tara" and "Lakshmi" with electricity has been sanctioned at a cost of about Rs.20,000. An indent for the plant will shortly be sent forward.—*Indian Engineering.*

**Anglo-American Telegraph Co.**—The directors have resolved, after placing £5,000 to the credit of the renewal fund, to declare an interim dividend for the quarter ended March 31 of 15s. per cent. on the ordinary stock and £1. 10s. per cent. on the preferred stock, less income tax.

**Power Bills.**—At the last meeting of the Essex County Council Alderman Russell, in reference to the opposition of the Council to the Electric Power Bills, moved that the opposition should be withdrawn, since they would cheapen the supply of electricity generally. The motion was lost.

**Hessle.**—The application of the Urban District Council to the Board of Trade for a provisional order for electric lighting has not yet been sanctioned, but the part referring to Soulcoates rural district having been withdrawn, the Council are sanguine as to obtaining the order for Hessle.

**Blaydon.**—The Urban District Council have sealed an agreement with the County of Durham Electrical Power Distribution Company, Limited, as to the electric lighting of the district, and the transfer to the company of the undertaking authorised by the Blaydon Electric Lighting Order, 1902.

**Large Bell.**—Not everything is made in Germany. We have just seen at the offices of Messrs. Fuller, McLeod, and Co., Norfolk House, Laurence Pountney-hill, E.C., an enormous electric bell, the disc of which has a diameter of 19½in., which is destined for railway track signalling at Berlin. It is worked by 12 dry cells in series.

**Stourport.**—A memorial, which was very numerously signed by tradesmen and residents, urging the Council to take such steps as would secure electric light for the district, has been referred to the General Purposes Committee for consideration. It suggested that the Council should ask the Kidderminster Electric Lighting Company to apply for a provisional order.

**Morley.**—Mr. J. E. Ellis, electrical engineer, in his last report states that the output from the electricity works during the month ending Feb. 28 was 15,149 units, and that the actual units sold to customers was 9,964, this being a decrease of 716 units in the output, and an increase of 1,150 units sold to customers the same period last year. The total number of lamps connected to date was 12,301.

**Poole.**—The Rural District Council have granted permission to the National Telephone Company to erect poles on the roadsides running through Talbot Village and Wallis Down, and also on two short sections of the Council's roads at Canford, in connection with the company's extension of their system to Wimborne. The County Council had already given their sanction in regard to their roads.

**Ulster Telephones.**—The work of connecting Londonderry, Coleraine, and Ballymoney with Belfast by telephone has been almost completed by the General Post Office, who have had charge of the undertaking, and they expect to open the system to the public on May 1. The price to be charged for a three minutes' conversation will be 2d. between Belfast and Londonderry, and 6d. for the other towns mentioned.

**Removal.**—Mr. George W. Green, A.M.I.C.E., M.I.E.E., has removed from 92, Victoria-street, S.W., to Crown Works, Guildford-street, Lambeth, S.E. The telephone number is changed into 7,733 Central; the telegraphic address remaining as before—viz., "Filicoid, London." The Harris Patent Feed-Water Filter, Limited, have removed to 82, Victoria-street, London, S.W. (telephone No. 876 Westminster).

**Transfer of Business.**—We are advised that the transfer of the business of the British Schuckert Electric Company, Limited, to Messrs. Siemens Bros. and Co., Limited, London, is now complete, and that Mr. Arthur Jacob, M.I.E.E., late general manager, has entered the service of the latter company. Further communications should be addressed York Mansions, York-street, Westminster, London, S.W.

**Norwich.**—The National Telephone Company have just reorganised and remodelled their exchange. The visual system of signalling and the central battery system have been introduced. The formal opening was made the occasion of a largely attended function, at which the directorate of the company was represented by Sir Cuthbert Quilter, M.P., and Mr. W. E. L. Gaine attended in his capacity of general manager.

**New Firm.**—The partnership heretofore subsisting between Edgar Arthur Braddick and Arthur Driffell Poulter, carrying on business as printers' and electrical engineers, at 18 and 19, Whitefriars-street, Fleet-street, London, and 43, Great Guildford-street, Southwark, under the style or firm of Braddick and Poulter, having been dissolved by mutual consent, Mr. E. A. Braddick has resumed business on his own account at 9, Gough-square, Fleet-street, E.C.

**Gillingham.**—Electric light is to be substituted for gas in various parts of the borough, and a canvass will be made prior to laying down private and public lighting cables opposite Kingswood-villas. The engineer in his last report shows that the equivalent of 40 8-c.p lamps had been connected to the mains since the last meeting, making a total of 14,169 8-c.p. lamps with 229 consumers connected, and that an application had been received for 25 8-c.p. lamps.

**Dunfermline.**—At the last meeting of the Electric Lighting Committee the reports of Mr. W. B. Sayers, Glasgow, and Mr. Alexander Waddell, gas manager, Dunfermline, on the question of an electric supply scheme for the burgh were submitted. Discussion was deferred. An opinion on the two reports was expressed by Mr. N. H. Cohen, London. It was stated that within a week or 10 days a commencement would be made with the laying of the cables from the generating station of the Fife Power Company at Townhill to Dunfermline and district.

**Middleton.**—In moving the adoption of the minutes of the Electricity Committee at the last Council meeting, Alderman Lord said the supply of energy for traction purposes had been below the average during the past month. This was accounted for to some extent by the fact that the Middleton Electric Traction Company had not used so much as usual, and the supply to the Manchester Corporation trams had also not been so great as usual. The electricity supplied for lighting purposes had likewise been less than was customary so far as the demand was concerned.

**Salisbury.**—During last week an electrical exhibition promoted by the Salisbury Electric Light and Supply Company was held at the County Hall, Salisbury, and was largely patronised. The exhibition was opened by the Earl of Pembroke, the light being switched on by Lady Muriel Herbert. Amongst those present were the Mayor and Mayoress (Mr. and Mrs. J. K. Dowden), Mr. W. M. Hammick (chairman of the Salisbury Electric Light and Supply Company), Miss Hammick, Mr. and Mrs. A. R Malden, and Mr. A. B. Randall (resident engineer).

**Mussoorie Electrical Supply Scheme.**—*Indian Engineering* says the undertaking for the electric lighting and water-supply scheme will be carried out practically on the sole responsibility of the sanitary engineer to Government, U.P. This is hardly fair to the Municipal Board, which have to provide the funds and make payments on the certificate of the sanitary engineer. Even their own engineer will be subject to the sanitary engineer, and the electrical engineer to the Government of India will not, it is said, be referred to under any circumstances in the matter.

**Worthing.**—The number of units generated from March, 1902, to March, 1903, was 288,550, and from March, 1903, to March, 1904, 357,682, showing an increase of 27 per cent.; and from March, 1904, to March, 1905, 476 249 units, representing an increase of 29 per cent. The gross income in the first two years was £3 864 and £5,020, showing an increase of 29 per cent.; and in the last year £6,450, showing an increase of 28 per cent. The Town Council have increased the salary of the resident electrical engineer (Mr. Porter) from £300 to £350 a year, and the salary of the assistant engineer from £120 to £130 a year.

**London Gazette.**—The partnership between Harry William Sutton and George Aaron Benton, carrying on business as electrical engineers at 8, The Exchange, Muswell Hill, London, N., has been dissolved by mutual consent. A receiving order has been made out on debtor's petition in the estate of Harry Thorpe, electrician and engineer, 11, Bartholomew-villas, Kentish Town-road, London. The first meeting will be held at Bankruptcy-buildings, Carey-street, London, on April 19 at 11 a.m. The last day for receiving proofs in the estate of Charles Aubrey Smith, electrician, 23, King-street, Regent-street, London, is April 20.

**Electrical Driving of Textile Mills.**—The worsted spinning mills of Messrs. Thomas Burnley and Sons, Limited, Gomersal, have recently been completely equipped with electric motors, and the whole mill is now driven electrically. The electrical energy is being purchased from the Yorkshire Electric Power Company, and therefore the boilers and main engines of the mill will no longer be required. The advantages of electrical driving of textile mills are well known and fully appreciated in other parts of the world, and now that the Yorkshire millowners can obtain a cheap supply of electricity "on tap" from the power company, Messrs. Burnley's example will, doubtless, be followed by others.

**Lowestoft.**—A balance-sheet of the electric lighting undertaking has been prepared by Mr. Charles F. Spencer, A.S.A.A., A.C.I.S. The accounts for the year ended Sept. 30, 1904, show an expenditure on revenue account of £7,597, and an income of £9,929, leaving a credit balance of £2,332. Interest on loans and sinking fund absorb £3,816, so that the deficiency for the year was £1,471. The capital account shows that the amount raised by loans to September was £61,220, of which £60,639 has been expended. The contributions to the sinking fund during the four years (£4,042) and the surplus of £4,037 appear in the accounts as "surplus of assets over liabilities," the total under this head being £8,0.0.

**Beckenham.**—The question of letting motors on hire is to stand over until the results of the experiments with the time switches have been determined. The claim of the British Insulated Wire Company's right to a percentage upon the meters supplied under the Westinghouse meter contract has been allowed. Revised charges for house services are under consideration by a sub-committee who are negotiating with the British Insulated Company on another matter for report. The matter of the arbitration *re* South Metropolitan Electric Light and Power Company is being urged forward. The South-Eastern and Chatham Railway Companies have promised to give attention to the

Digitized by Google

Council's request to the establishment of public telephone call offices at Beckenham Junction, Kent House, Penge, and Clock House railway stations.

**Water Power.**—Good progress has been made with the canal from the Spey, which is to provide the power to actuate the two turbine wheels to drive the dynamos which will provide electric light for Gordon Castle and Fochabers. The work is in the hands of Messrs. Drake and Gorham. The wiring of Gordon Castle is being proceeded with, and Fochabers has secured electric light at the cost of 5s. per 16 c p. lamp per annum, without having to bear any further share in the cost of the installation. The canal from the Spey will be about a mile long, and will act as a dam during its whole length, there being but about 1½ft. fall upon it. The body of water which it will contain will be about 12ft. broad and 4ft. deep.—The Swedish State Railways Department propose to buy a waterfall at a cost of 4,000,000 crowns for the purpose of producing electric power.

**Partick.**—The Town Council have adopted a report in which the Electric Lighting and Destructor Committee stated that they had agreed that considerable extensions of plant were necessary. Altogether about £13,000 was required, but £4,000 of this was to pay for material used according to contracts given out during last year. There had been a breakdown of the large engine in February last, and if this breakdown had occurred in December they would have been under the necessity of cutting down the supply of electricity. Their plant was practically all in use, and the committee now recommended the duplication of the large engine. There had been an increase of nearly 80 per cent. in the demand for current, and so it was absolutely necessary that they should have sufficient plant. Last year their profit had been £405, and their estimate for next year was at least £880 after providing for the new plant.

**Nelson Telephones.**—At the last Town Council meeting the town clerk read the following letter from the secretary of the Nelson and District Manufacturers' Association: "In consequence of a report made to me by several members of the association as to the inefficiency of the telephone service at Nelson, more particularly with regard to the trunk service, I asked the members to take careful note of the day, hour, and minute of every trunk call made, and the time at which the connection was effected during the month of December. From the report received I find that the average time taken in getting 349 trunk call connections was 23¾ minutes. This is very unsatisfactory, and I am desired to ask you to bring the matter before the notice of the Town Council, and ascertain whether the Council will be prepared to co-operate with this association in endeavouring to secure more satisfactory service." At a meeting of the General Purposes Committee it was resolved to agree with the complaint, and a sub-committee, consisting of the Mayor, Alderman Reed, and Councillor Smith, was appointed.

**Telephone Exchange Fire.**—During the evidence at the resumed inquest held on the 11th inst. into the two fires which broke out simultaneously in the premises of the National Telephone Company at Mansion House-chambers, 11, Queen Victoria-street, and 1 and 2, Oxford-court, Cannon-street, on the morning of Tuesday, Feb. 28, Mr. C. B. Clay, the metropolitan superintendent of the Telephone Company, gave evidence, and said the accident was attributable to the carelessness of a workman in allowing the cable to come into touch with the live rail. He did not consider that there was even any danger of subscribers who might have been using their instruments at the time receiving a current of 500 volts, because the wires would not carry it. It appears that both offices are of a somewhat antiquated construction, and had no heat coils, although part of one of the cables in question communicated with the Gerrard-street exchange. The accident did not affect that exchange, because there the heat coils blew and protected the apparatus. Heat coils were not in use when the other exchanges were fitted, as heavy currents were extremely rare, and they were not modernised because the company were going to close them.

**Paddington.**—At the last Borough Council meeting the General Purposes Committee recommended that the solicitor be instructed to prepare an agreement between the Council and the Metropolitan Electric Supply Company on lines as follows: "Borough Council not to insist upon compliance with Clause 21 of provisional order, provided that the company should establish and maintain at Willesden a sufficient generating station for Paddington, separate and capable of being completely severed from other generating stations and plant of the company. That the Borough Council shall have the same rights of purchase of such generating station and plant as they would have under the Act of 1888 and the provisional order in the case of generating station and plant within the borough, but that they should be at liberty to purchase the company's Paddington undertaking without the obligation to purchase Willesden plant or station. That the site at Amberley-road be retained by the company with or without plant, and the Borough Council shall be at liberty at time of purchase of undertaking to purchase site with such plant. That the Borough Council may purchase either site with plant, or both at their option. That in the event of Willesden site not being purchased, the Borough Council are not to buy outside mains. That in the event of the company obtaining powers to supply the whole of the borough, the above conditions shall apply to the added portion. That the obligation of the company under Act and orders shall be deemed to apply to Amberley-road and Willesden sites, subject to the above conditions." The solicitor had informed the committee that if the Council were satisfied that there was no engineering or other difficulties in the option proposed to be given to the company, he saw no legal objection to the heads of agreement, but was of opinion that the agreement, if executed, must be scheduled to an Act of Parliament. An amendment was carried that the matter be referred back that they might obtain expert advice, but as the clock struck one before it could be put as the substantive motion it was not carried technically, and the whole matter was adjourned.

## PROVISIONAL PATENTS, 1905.

MARCH 31.

3855A **Improvements in apparatus for use in starting, stopping, and reversing electric motors.** Ernest Sherwood Woollard Moore and William Brabiner Bennitt, Prince's-chambers, Wolverhampton. (Date applied for under Patents Rule 9, Feb. 24, 1905.)

APRIL 3.

6954. **Improvements in electrical prepayment meters.** Chamberlain and Hookham, Limited, and Sydney Holmwood Holden, 4, New Bartholomew-street, Birmingham.

6958. **Improvements in and relating to safety devices for overhead wires for electric traction and other purposes.** Henry Ridley Burnett, Roman House, Abbey-road, Barrow-in-Furness.

6989. **An electrical time cut-off for motors and the like.** George Moore and Joseph Henry Hirst, 2, Belvoir-street, Hull.

6994. **Improvements in and connected with separators for the plates of batteries and the like.** William Frederick Newcomen, 48, Pulteney-road, South Woodford, Essex.

7004. **Improvements in electric furnaces.** Alleyne Reynolds, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

7006. **Improvements relating to the generation of electricity by means of earth cells.** Emil Jahr, 73, Cheapside, London. (Complete specification.)

7008. **Improvements in safety circuit closers.** Leon Ottinger, 18, Southampton-buildings, Chancery-lane, London. (Complete specification.)

7010. **Improvements in and relating to methods of receiving electrical impulses.** Daniel Watts Troy, 18, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents Act, 1901, April 8, 1904, being date of application in United States.) (Complete specification.)

7019. **Improvements in or relating to electrical contact breakers.** George Bowron, 111, Hatton-garden, London.

7020. **Improvements in or relating to electrodes for electrolysers used in the manufacture of bleaching liquors.** Richard Kother, 111, Hatton-garden, London. (Complete specification.)

7035. **Improvements in and relating to electrical conductors.** John Frederick Dake, 70, Chancery-lane, London.

7036. **Improvements relating to electrically-propelled vehicles.** August Weiss, 322, High Holborn, London.

7048. **Improvements in electric temperature controlling devices.** James Esten de Jersey, 28, New Bridge-street, London.

APRIL 4.

7068. **An improved holder or carrier for the shades of electric lamps** Joseph Andrews and Joseph Andrews, jun., 77, Colmore-row, Birmingham.

7075. **Electrically-controlled device for operating valves of internal combustion engines.** James Alexander Main, 65, Chancery-lane, London.

7082. **Electrical alarm mat.** John Skinner, 44, St. Mary's-street, Southampton.

7095. **Improvements in arc lamps** John Morrecraft Wellington and Walter Francis Daniell, 88, Chancery-lane, London.

7101. **Apparatus for absorbing gases by a liquid under the action of the silent electric discharge.** Alexandre de Hemptinne, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Complete specification.)

7105. **Improvements in electrical cables.** W. T. Henley's Telegraph Works Company, Limited, and Henry Savage, 53, Chancery-lane, London.

7111. **Improvements in or connected with magneto-electric generators.** Louis Alexandre Gianoli and Raoul André Perrin, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents Act, 1901, April 14, 1904, being date of application in France.) (Complete specification.)

7121. **New or improved means of attaching the globes of electric arc lamps** Henry Baggett and the New Century Arc Light Company, Limited, Norfolk House, Norfolk street, London.

7124. **An improved telephone system.** William Phillips Thompson, 6, Lord-street, Liverpool. (A/S Elektrisk Bureau, Norway.)

7133. **Improved electric regenerative battery.** William Holloway Fellows, Edward Thomas Pickup, and William Tice, 173, Fleet street, London.

7148. **Improvements in and relating to electric motor control systems applicable for electrically-propelled trams or vehicles.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (General Electric Company, United States.)

7149. **Improvements in and relating to electric motor control systems applicable for electrically-propelled trams or vehicles.** The British Thomson-Houston Company, Limited, 83 Cannon-street, London. (General Electric Company, United States.)

Digitized by Google

**7136. Improvements in the electric lighting of trains.** Henry Leitner and Richard Norman Lucas, 4, South-street, Finsbury, London.

**7150. Improvements in and relating to systems of electric motor control applicable for electrically-propelled trams or vehicles.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (General Electric Company, United States.)

APRIL 5.

**7159. Improvements in telephone apparatus.** Bernhard Ehrlich and Max Konrad, 6, Bank-street, Manchester. (Complete specification.)

**7176. Improved method of operating the points of overhead trolley wires, and also of the rails for electric tramways.** John Greenwood and Son, Windsor Bridge Works, Salford, Lancs.

**7197. An electric current reversing switch, lamp socket, and plug combined.** Herbert Rhodes Edward Perkins and Joe Blakey, 23, Spencer-street, Park Grove, Barnsley. (Complete specification.)

**7211. Improvements in or relating to electric clocks.** Henri Alfred Campiche, 111, Hatton-garden, London. (Complete specification.)

**7448. Improvements in electromagnetic or eddy-current brakes and electromagnetic clutches.** David King Morris and George Auslow Lister, The University, Birmingham.

**7498. Improvements in air-insulated telephone and telegraph cables.** Emanuel Jensen, 321, High Holborn, London. (Date applied for under Patents Act, 1901, April 9, 1904, being date of application in Denmark.) (Complete specification.)

**7566. Improvements in telephone transmitters.** Harry Merton Gail, 18, Southampton-buildings, Chancery-lane, London. (Complete specification.)

## COMPLETE SPECIFICATIONS ACCEPTED.

*To be published April 27.*

1904.

**5213. Controlling electric motors.** Geipel, Lange, and Mascord.

**5214. Controlling electric motors.** Geipel and Lange.

**8693. Electric arc lamps.** Ganz und Co. Eisengiesserei und Maschinenfabriks Akt.-Ges. (Date applied for under International Convention, May 9, 1903.)

**8694. Alternating-current arc lamps.** Ganz und Co. Eisengiesserei und Maschinenfabriks Akt.-Ges. (Date applied for under International Convention, July 24, 1903.)

**10836. Registering apparatus for gas, electricity, water, or other fluids.** Henderson and Higgin.

**11077. Railway or tramway signalling systems.** British Thomson-Houston Company, Limited. (General Electric Company.)

**11141. Winding of armatures of dynamo-electric machines.** Ker and Paterson, Cooper, and Co., Limited.

**11156. Manufacture of electric cables.** Beaver and Claremont.

**11363. Apparatus for use in the distribution of alternating current.** Berry.

**12313. Electrical timing devices for fire brigade competitions, military drills, race meetings, and the like.** Nichols and Brown.

**12467. Electrically-driven fans.** Veritys, Limited, and Walker.

**12741. Electric ignition apparatus for internal combustion motors.** Du Cros. (Soc. Anom. des Anciens Etablissements Panhard et Levassor.)

**12840. Electrical train describer or indicator.** Wells.

**13136. Electrically-heated gauffer moulds and other similar apparatus.** Boult. (Soc. Dubois et Emery.)

**13173. Apparatus for providing air, light, and telephonic communication for use at fires.** Merryweather.

1905.

**257. Electric arc lamp electrodes.** British Thomson-Houston Company, Limited. (General Electric Company.)

**2474. Process for neutralising static electricity.** Chapman.

**2939. Electric incandescence lamp fittings.** Suter.

## NOTES.

**The Institution.**—We have received a copy of the Institution *Journal*, dated April, which contains the following papers, with discussions: "The Combination of Dust Destructors and Electricity Works Economically Considered," by W. P. Adams; "Fuel Economy in Steam-Power Plants," by W. H. Booth and J. B. Kershaw; "Compensated Alternate-Current Generators," by Miles Walker (Manchester); "High-Tension Switchgear," by L. Andrews (Manchester); "Armature Reaction in Alternators," by J. B Henderson and J. S. Nicholson (Glasgow); "Condensing Arrangements in Central Stations," by J. D. Bailie (Leeds); and "The Magnetic Properties of some Alloys of Iron and Silicon," by Thos. Baker.

**Pyrotechnics.**—During the thunderstorm on Sunday afternoon St. Mathias's Church, Richmond-hill, was severely damaged by what is described as a fireball. Following a vivid flash of lightning, there descended from the clouds, according to several spectators, a huge ball of fire, which exploded with a loud report near the church steeple. A hole was torn in the roof, through which a brilliant glare appeared, while outside pedestrians are reported to have been almost thrown to the ground. The church is illuminated by electricity, and the glass doors of the switch-boards were blown outwards and broken to pieces. On examination it was found that several of the electric light wires had fused. The Lightning Research Committee should be able to get some useful data from this occurrence as to ball lightning.

**Eddy-Current Brakes.**—A paper on "The Eddy-Current Brake for Motor Testing" was presented at a meeting last week of the Birmingham Local Section by Messrs. D. K. Morris and G. A. Lister. The authors pointed out that the eddy-current brake had many advantages over the band or rope brake for motor testing. Among these were sensitiveness, combined with convenience of adjustment to exact balance, uniformity of load and constancy after final temperature conditions have been reached. The heat produced in the energy-absorbing element is not conducted to the bearings. The brake also gives a retarding torque only. The brake was described in detail, and, in conclusion, the authors claimed that, besides being the most convenient and compact for ordinary motor testing, it compared favourably, when correctly designed, with mechanical water-cooled brakes on all points except that of initial cost.

**The American Institute.**—The nominee for the presidency of the American Institute of Electrical Engineers is Dr. Schuyler Skaats Wheeler, who was born at New York in 1860. He was educated at Columbia University, and his early experience in the electrical field was in the direction of electric lighting and central-station work. In 1886 he went into the manufacturing field, first as electrician to the Herzog Teleseme Company, subsequently becoming connected with the C. and C. Electric Motor Company. Mr. F. B. Crocker was associated with the latter concern, but after a time the two severed their connection with that company, and organised the Crocker-Wheeler Company. Dr. Wheeler has had a varied experience of electrical matters, and as he is credited with a true engineering mind, as well as great executive and business ability, his election is regarded as practically certain.

**The Telephone Transfer.**—A discussion arose in the House of Commons on Tuesday evening with reference to the constitution of the Select Committee which is to consider the agreement between the Postmaster-General and the National Telephone Company. Lord Stanley, replying to a question, stated that he hoped the matter would be treated as non-controversial, and that the motion to appoint the committee would be agreed to as soon as possible. Certain objections as to the constitution of the committee had been made, and these objections had been met, so he did not think it necessary to appoint a day for debating the subject in the House. In reply to another question, his lordship added that what he had promised was that the House should have an opportunity of considering the agreement before it became effective, and he thought that Parliament would be in a more favourable position to arrive at a conclusion if they had the report of a Select Committee before them.

**Obituary.**—Mr. John Verity, who died at Hailey, Oxon, on the 6th inst., at the age of 41, took a prominent part in the development of electrical industry in this country. In the early days he turned his attention to adapting electric light to domestic use. Joining hands with Mr. Edison, whose personal friendship he enjoyed, his efforts culminated in the great display of incandescent lighting at the Crystal Palace Exhibition of 1882, which did so much to popularise electric lighting in this country. In conjunction with the late Sir James Pender and Sir George Elliot he founded the Metropolitan Electric Supply Company, which came into such prominence in connection with the proceedings of the St. Marylebone Borough Council's electric lighting scheme. As chairman of Verity's, Limited, he was a large employer of labour in Birmingham and Manchester. Mr. Verity was high sheriff for the county of London in 1901, and was a justice of the peace for the county of Warwick. He married in 1897 the eldest daughter of Mr. Henry Lubbock, of Newberries, Herts, who, with four children, survive him.

**Electro-Therapeutics.**—An inquest was held on Saturday last upon the Hon. Mrs. Monck, who met her death at Charing Cross Hospital while under electrical treatment. It is tolerably clear from the medical evidence that this was entirely a coincidence, and that death was in no wise attributable to the treatment. Deceased was suffering from gout in the arm and underwent several electric light baths. These, apparently, did not have much effect, so she was treated with high-frequency current, which she thought was beneficial. On the last occasion that deceased was under this treatment the physician observed perspiration break out on the patient's face and immediately stopped the current. Death occurred shortly afterwards. A *post-mortem* examination showed that deceased was suffering from Bright's disease, death being due to rupture of a cerebral artery. Two physicians corroborated the hospital surgeon's view that death occurred quite irrespective of the electrical treatment, and an ordinary verdict was returned. It is as well that the Press has given due publicity to the medical evidence, as a section of the community are apt to be prejudiced against electricity through coincidences of this kind. Even the coroner, though he had no difficulty, after the evidence, in accepting an open verdict, appeared inclined at first to regard electricity as some kind of occult medium.

**Trolley Contact Spring.**—The Illinois Circuit Court recently gave its decision in the case of the General Electric Company *v.* the Morgan-Gardner Electric Company. The plaintiffs are the proprietors of the Anderson patent, No. 412,155, for a trolley contact spring, the validity of which has been vindicated in preceding suits. The particular feature alleged to be infringed was that covered by Claim 8 of the patent, which calls for the combination of a trolley frame and wheel with metallic conducting brushes between the hubs of the wheel and the frame The specification provides for brushes connected at their

Digitized by Google

base with the cross bar of the trolley frame at each side. The first diagram in the specification shows the brush connected at its base with the inside of the cross bar; the third diagram shows the brushes carried through the frame, so that the base of the brush rests on the outside of the frame. The defendants' device is identical with that of the plaintiff's patent, except that the base of the brush spring is made fast to the outside of the frame in a countersunk channel, and then carried inside the frame and extended to its position between the end of the hub and the frame. It will be noted that the claim does not attempt to restrict the manner of resting the brush spring. It only provides that the combination shall operate substantially as described. The defendants' device operates in a substantially similar manner. The Court decided that defendants' device was a palpable infringement, and therefore gave judgment for the plaintiffs.

**A New Society.**—For some considerable time past there has been a strong feeling on the part of the electrical engineers in the Post Office service that the great developments in every branch of telegraph and telephone engineering, and the increasing responsibilities of their position, justified the formation of an organisation which would enable them, by the exchange of opinions on matters of interest, to keep abreast of the rapid progress in various directions, and also to remain in touch with their colleagues, scattered, as they are, over the whole of the British Isles. A conference, attended by over 100 engineers, including the majority of the officers stationed within the metropolitan area, and also delegates from England, Wales, Scotland, and Ireland (the latter representing a staff of more than 200 engineers), was held in London on the 8th inst., when after a lengthy discussion it was unanimously resolved to form an organisation under the title of "The Society of Post Office Engineers." It was decided that the administration of the affairs of the society should be vested in the hands of a president, vice-president, treasurer, secretary, and a council of eight members. The following election of officers took place: president, Mr. D. H. Kennedy (London); vice-president, Mr. P. Jarvis (Sunderland); treasurer, Mr. J. M. Crawford (London); secretary, Mr. J. W. Atkinson (London). Arrangements were made for the election of the council at an early date, and a sub-committee, comprising the officers and five other engineers, was appointed to draft the rules of the society on lines indicated by the conference. It is anticipated that by means of lectures and papers the society will materially promote the interests of its members.

**New Publications.**—We have received the April number of the *Electric Club Journal* (Pittsburg), which contains articles on "Single-Phase Line Construction," by Theodore Varney"; "Electro-Pneumatic System of Train Control," by P. C. McNulty, jun.; "How to Remember the Wire Table," by Chas. F. Scott; "Protective Apparatus," by N. J. Neall; "Engineering Shorthand," by Geo. A. Wardlaw; "One Side of Construction Work," by W. H. Rumpp; a continuation of the series on "Factory Testing of Electrical Machinery," by R. E Workman; and "Taping," by C. Stephens. There is also an address delivered at the annual banquet of the Westinghouse apprentices by Mr. D. O. Hales, an apprentice from New Zealand. Mr. Hales, who has spent some years in an American workshop, contrasts the apprenticeship system of that country with that obtaining in England. On applying to an English electrical firm he was informed that they would take him for a three years' course in return for a premium of £300. In the States a large company not only provided him with the course without premium, but paid him while doing so. Mr. Hales thus summarised the advantages of the Westinghouse apprenticeship course: "First, I have had the chance of being a unit in a great organisation, and of observing some of the details of that organisation; second, I have come into personal contact with men who have distinguished themselves in engineering and scientific work; and I have worked with the working-man as a working-man." Mr. Hales considers the last of these a great factor, as when the apprentice becomes an engineer or manager he will be able to understand his men's character and environment much better.

**Motor Controllers.** — The Illinois Circuit Court recently gave its decision in the case of the Thomson-Houston Company *v.* the Morgan-Gardner Electric Company. Patent No. 393,323, granted in 1888 to George Herbert Condict for a system of control for electric railway motors, vests in the plaintiffs, who alleged that Claims 10, 21, 22, 27, 29, and 31 had been infringed. Claim 10 calls for a reversing switch, arranged in the same case with the controlling switch and "combined with a locking device which is operated by the controlling switch so that when current is flowing through the motors the reversing switch cannot be moved," but which can be moved when the current is substantially cut off, and which is operated simultaneously with the controlling switch and by the same handle. Claims 21 to 31 relate to a controller wherein "the regulation of the introduction of electric current to motors is effected by means of the combined use of both the rheostatic or dead resistance coils and live resistance coils, so adjusted as to avoid the loss of energy and the danger arising from sparking or short-circuiting during changes of circuit connection, and also by means of placing the manipulation of the current under the control of one handle or its equivalent device." The validity of the patent had been sustained in previous suits. Defendants not only denied infringement, but contended that the plaintiffs had been guilty of laches and were seeking to destroy competition. The defendants' device consisted of a controller and reverser in one case, governed by a single handle. The motors are protected from injury during change of current by the introduction of auxiliary resistance, and dead resistance and live resistance coils are used in combination. The Court held that any difference between the devices of the two parties was merely one of detail, the principle being substantially the same in both cases. The questions of laches and monopoly could not properly be raised in the suit. Plaintiffs would be granted the interim injunction asked for.

**Electrically-Heated Carbon Tube Furnaces.**—At the Faraday Society last week Messrs. R. S. Hutton and W. H. Patterson contributed a paper on this subject. The authors observed that this type of furnace seemed to be the most readily available for the very highest temperatures, and they had been able to get satisfactory results with a very simple type of construction. The important points to bear in mind are the end connections (which must be kept cool), protection of the tube from contact with air, and heat insulation. Two types of furnace were described as follows: Graphite tube furnace: this is bored from a solid rod of Acheson graphite and screwed into graphite plates which form the end connections, the latter being clamped to copper holders. The central thinner portion of the tube is surrounded with carborundum or other heat insulator, and the material to be heated is placed in small carbon boats. In a 1·5cm. tube (internal), 320 amperes at 9·6 volts melt platinum in 16½ minutes. Agglomerated carbon tube furnaces: these are more suitable than the former type when much experimental work has to be done, and the tubes can be readily obtained. The ends of the tubes (which are too hard to be worked) are coppered electrolytically and soldered to

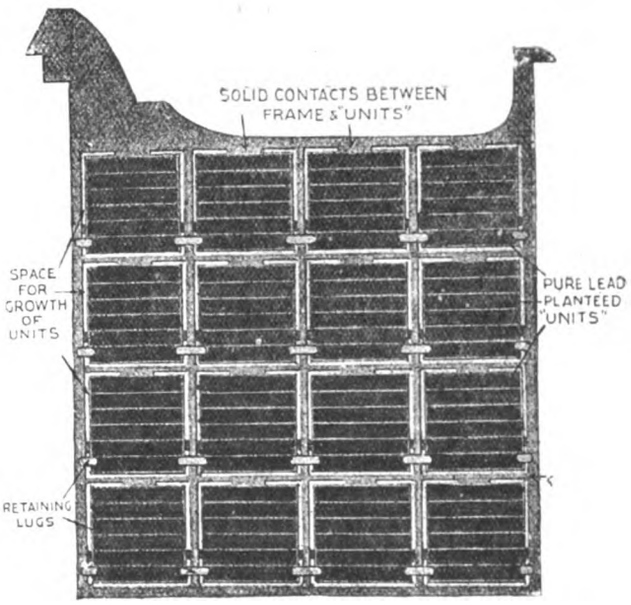
Digitized by Google

copper tube extensions, provided with water-jackets to keep the joint cool. Into these the current is led by copper clamps, and glass tubes for the passage of gases, etc., are connected by means of rubber stoppers. Carborundum kept in place with an external asbestos tube serves as the jacketing material, as before. Tube furnaces up to 67mm. internal diameter have been successfully made. It is hoped to use these in a vertical position, so that large crucibles may thereby be heated. In such a tube 850 amperes at 13 volts melt nickel in 12 minutes and platinum in 20½ minutes. In a special tube furnace for experiments in atmospheres of pure gases (free from carbon monoxide), the furnace proper is surrounded by an outer jacketed carbon tube, also provided with water-cooled copper extensions, and the joint between the two is gas-tight. Hydrogen is passed through the space between the tubes. In a later paper full details as to current and temperature measurements will be published.

**An Electrical Rolling Road.**—After some three years of experiment, an electrically-driven "rolling road" has been put into operation at Cleveland, Ohio, for the purpose of conveying loaded wagons up a steep incline. The "road" consists of a moving platform, 8ft. wide, which revolves around sheaves at either end. Its length is 420ft., and the elevation attained is 65ft. The promoters selected this as the most difficult site in order to thoroughly test the device. Four 40-h.p. compound-wound motors, operating under a single controller, are used to work the mechanism. It was essential that the motors should act in complete unison, as a slight variation in starting or stopping them, or in the speed, would be liable to distort the platform. The motors, which are arranged one at each end, with the other two between equidistant to each other, revolve at 850 revolutions per minute, and are provided with a 17 to 1 reduction gear. Each carries a sprocket chain 36ft. long, running over wheels at each end, and these in turn engage a large chain running the entire length of the platform. This is accomplished by placing teeth on the outer side of the motor chains, which engage the endless chain both above and below, so evenning up the pressure on the platform. The endless chain is placed in the middle of the belt, so that the power exerted is distributed evenly. The small chains, by engaging above and below at the same time, actuate a large portion of the entire length of the platform continually. Owing to the great weight of the platform—106 tons—it was at first thought that it would be almost impossible to operate it, but when it is considered that the returning half is descending the grade underneath the ascending half, it will be seen that the power required is only that needed to overcome friction and to raise the wagons. The motors may be worked in series or parallel, and are operated similarly to street car motors. The "road," which is described in the *Western Electrician*, is not kept in continual motion, as it is necessary to stop it for the vehicles to be driven on and off. It has been found that the contrivance is of great value in economising time in the district served. In view of the frequent stopping and starting of the roadway, we doubt if it has much advantage over an electric lift.

**Arc Lamp Improvements.**—An interesting discussion took place at a recent Chicago meeting of the American Institute of Electrical Engineers as the result of a paper by Mr. George A. Eastman upon numerous tests made by him to determine the most suitable size of carbons to be used with arc lamps of 5 and 3·5 amperes capacity. The author's tests have served to emphasise the conclusion that smaller carbons than are now common should be used. Mr. Eastman favours $\frac{5}{16}$in. carbons for lamps of five amperes and less. By the use of such carbons, as compared with ½in. carbons, he found that the efficiency is increased in the five-ampere lamp from 2·5 watts per mean spherical candle-power to 1·8 watts, while on the 3·5-ampere lamp such a reduction increases the efficiency from 3·4 watts with the ½in. carbons to 2·2 watts with the $\frac{5}{16}$in. carbons. With the smaller carbons it is impossible for the crater to wander from one side of the lamp to the other, as it does in the ordinary enclosed arc, due to the fact that there is not room on the carbon tips for much wandering at the crater. This makes the light of the smaller carbons very much steadier. In the ordinary arc lamp the light at any given point varies between maximum and minimum values in the ratio of at least 1 to 3, because of the wandering of the arc between the blunt carbon ends. Another important gain by the use of smaller carbons is in the colour of the arc. The light is much nearer the sunlight in quality with the smaller than with the larger carbons, because with the latter the arc has a violet tint. The author found that any outlay occasioned by increased cost of trimming or higher price of the smaller carbons was more than counterbalanced by their higher efficiency. Mr. V. R. Lansingh described recent attempts to correct the natural distribution of light around an arc lamp so as to better adapt it to street-lighting where it is desired that the greatest amount of light shall be thrown about 15deg. below the horizontal, instead of 40deg. as in the ordinary direct-current arc lamp. He had found that the best combination of clear and opal globes for outdoor lighting was provided by an opal inner and a clear outer globe. As far as the ordinary types of globes were concerned, the illumination at great distances away from the arc, as in street-lighting, was much better with this combination than with clear inner and outer globes. The best results were obtained with a new type of Holophane bell shade of rather peculiar design.

**Accumulator Plates.** — A type of accumulator termed the "Unit" has been designed by the National Battery Company, of Buffalo, N.Y., having for its object the prevention of abnormal chemical deposits on the positive plate.



These deposits often lead to distortion of the plate. The Unit accumulator, which is described in the *Western Electrician*, is specially designed for high charge and discharge rates, combining long life and high efficiency, and is constructed in such a way that the units are firmly attached to a rigid frame, thus insuring full contact between the two during the entire life of the plate. Both sides of the accumulator are uniform, and in addition its mechanical structure is strong, holding the active material closely to it.

Digitized by Google

The accompanying illustration shows one of the plates. Sufficient space is left on all sides of the unit to allow for the natural growth of the plate. This does away with buckling. In the construction of the positive plate no attempt has been made to prevent the natural growth of the active material portions. The units, or active portions, are hung in a rigid lead frame, with ample space at the bottom and at the two sides of each unit to allow for expansion without straining or distorting the supporting frame. The pasted type of negative has been adopted, and a grid developed in which the natural molecular shrinkage of the active material has been provided for and utilised so that the contact is maintained as the shrinkage progresses, owing to the fact that the active material enclosed in the contact portions is drawn more tightly around the grid projections or pins. A negative plate which loses its contact by shrinkage will cease to give its full capacity as this physical change takes place.

**Electromagnetic Clutch.**—A new type of electromagnetic clutch for machine-tool drive has been devised by the Williams Electric Machine Company, of Akron, Ohio, of which a description appears in the *Western Electrician*. The mechanism operates on the principle of the friction disc, the disc being clamped by magnetic action induced by the energising coil concentric with the shaft, as shown in the accompanying

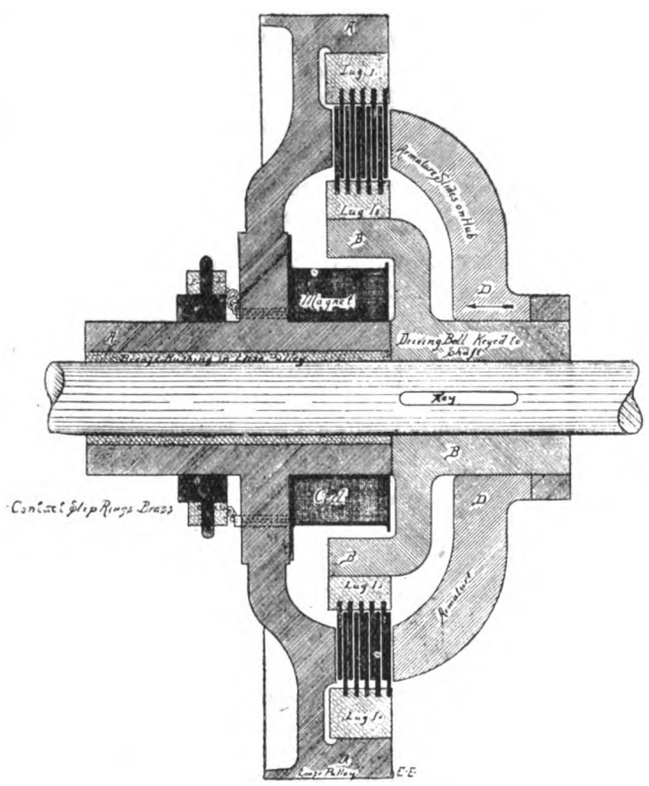


diagram. The magnet coil is energised through the contact slip-rings, and is enclosed in an oil and waterproof case, so that the clutches can be run in oil if required. Interleaved driving discs are mounted through their respective key lugs—one-half on the driving member, B, and one-half on the driven member, A. As the driving discs are loosely fitted to these key lugs, the armature, D, when magnetised by the action of the coil, slides on the hub, B, and presses against the driving discs and brings their surfaces into close contact. This action also reduces the reluctance of the magnetic circuit, and automatically increases the disc clamping effect, which in turn increases the transmitting power of the clutch. The multiple interleaved discs introduce into the magnetic circuit a number of minute air-gaps in series. On cutting off the current from the energising coil the release of the clamping effect on the discs causes these air-gaps to open, and the rotative action of the discs on the driving member accentuating this condition, the objectionable residual effect is entirely overcome. The gripping power of the clutch may be increased to practically any point desired by simply decreasing the resistance in series with the magnet coil, and thereby allowing more current to flow through it. The current needed to energise the magnet coil is quite small.

**Electric Railway Tests.**—The work of the St. Louis Electric Railway Test Commission is approaching completion, tests having been carried out respecting the alternating-current losses in rails, the efficiency of various methods of braking and accelerating both city and inter-urban cars, the energy consumption in cars with different kinds of service, and the resistance offered by the air to the motion of cars at high speeds. A feature of interest is provided by the special dynamometer car designed for the purpose of measuring directly the head and rear air-pressures and the side and roof resistances of car bodies. An ordinary car body is located upon a flat steel car frame by means of rails screwed to the floor of the frame, enabling the car body to move freely along same. A special steel vestibule and a standard vestibule are provided with this car. Under the side sills of the dynamometer body are mounted eight Chapman double-ball bearings, and these carry four axles of $3\frac{7}{16}$in. diameter, 9ft. long. Upon the axles are specially chilled wheels 12in. in diameter with ground treads. The rails are also ground where they come into contact with the wheels. By this method of mounting there is, for practical purposes, no friction between the body and the flat car floor. The body is restrained from excessive motion by various effective safety devices. The pressure of the air upon the body is measured by means of scale beams, which are supplied with dash-pots, and the weighing mechanism consists of the regular beam with weights and poise. A spring balance with dial is employed to render easier the manipulation of the machine. For the purpose of separating the head and rear resistances from the total the vestibule is independent of the body, but is carried therefrom by means of a link suspension. In order to guide the vestibule and to transmit the pressure to the weighing device, a steel-trussed oak frame, attached to the vestibule, projects into the car a distance of 8ft., and is guided on all sides by small Chapman bearings. To secure stability of the vestibule and body, each of these is held against the scales by counterweights, the forces of which are transmitted through bell cranks and levers, all equipped with knife-edged contacts. In order to gain exact results two independent plans are employed. The test track, over 25,000ft. in length, is divided into sections of 1,000ft. each. The instant of passing each section is indicated on the graphical record of a General Electric ammeter, which is also used for the current record. This ammeter records upon a strip of paper at regular intervals of five seconds each. Upon this record is superimposed the time of passing each of the sections, this being accomplished by closing a switch for an instant as each of the sections are passed. Thus the time of passing through a section is accurately recorded. The second speed device consists of a small dynamo carried upon the truck frame and geared to the car axle. It has permanently magnetised field poles, but these also carry exciting coils, through which the field current of the recording ammeter is also passed. The E.M.F. generated by the dynamo is read upon a specially arranged voltmeter, the readings being directly proportional to the speed. The tests will continue until sufficient data are available to determine the air resistance to the motion with different shapes of car front at all speeds up to 70 miles an hour.

**The Tantalum Lamp.**—Some tests on tantalum lamps are described in the *Electrical World* of New York by Messrs. A. E Kennelly and S. E. Whiting. Ten lamps were obtained from Messrs. Siemens and Halske, all of which had frosted globes, and were understood to be of 110 volts and 22 c.p. Figs. 1 and 2 indicate the behaviour of one of these lamps in regard to resistance, current, power, luminous intensity, luminous efficiency, and specific consumption. The corresponding data are indicated also, in dotted lines, for an Edison carbon-filament lamp nominally of 120 volts, 16 c p, and 3 1 watts per candle, in a frosted globe. This particular lamp was taken at random from a number of similar lamps which had been in service about 50 hours. The tantalum filament had an initial resistance of about 55 ohms at the normal room temperature and lowest voltage. It rose rapidly at first, and afterwards more slowly as the terminal voltage increased. The highest resistance observed was 316 8 ohms at 143·3 volts. The resistance was still rising at this point, as shown by the curve. Whereas, therefore, the carbon filament falls,

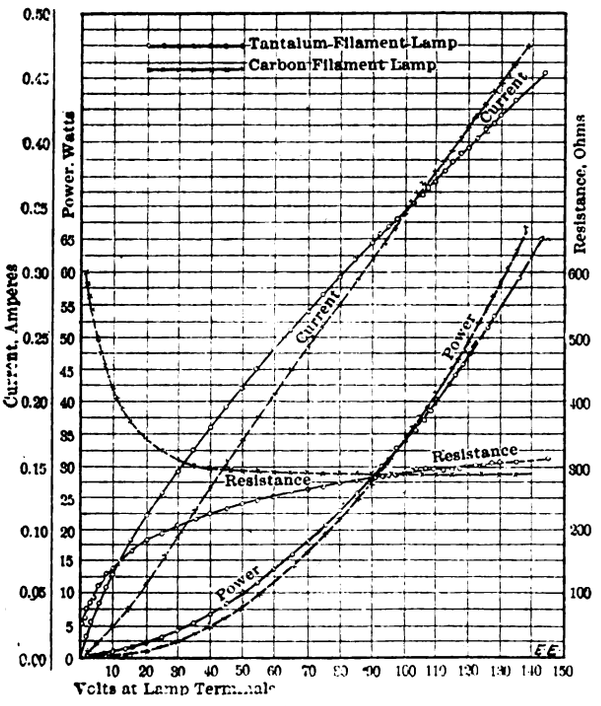

FIG. 1.

under operation, to about half its cold resistance, the tantalum filament rises, under operation, to about 5½ times its cold resistance. On this account the initial rush of energy into the tantalum filament must be about 10 times as great as in the carbon filament. The time allowed for the tantalum filament to reach its working temperature is, by inference, materially less than for the carbon filament. It would be interesting to investigate, from this standpoint, the possible influence of frequent turning on and off upon the lifetime of the tantalum filament. Under operative conditions the carbon filament has sensibly constant resistance for the working range of voltages. The tantalum filament increases in resistance about one-fifth of 1 per cent. per volt increase of terminal pressure, in the neighbourhood of its normal working voltage. On this account, a given percentage increase of voltage on the tantalum lamp will not produce the full corresponding increase in current strength. Thus, an increase of terminal voltage of 5 per cent. would increase the current only about 3¾ per cent. Such a property is valuable, since it tends to regulate automatically the current strength passing through the lamp under variations of line voltage. The effect in these tantalum filaments is not, however, very marked at their normal working point, and not so great as the curve shows it would be at a much lower pressure, say at 20 volts. Here an increase in voltage of 5 per cent. would cause an increase in current of only 2¾ per cent. The curve of current strength in the carbon filament is not far from a straight line through the origin. The corresponding curve in the tantalum filament starts rapidly, but droops considerably owing to the increase of resistance.

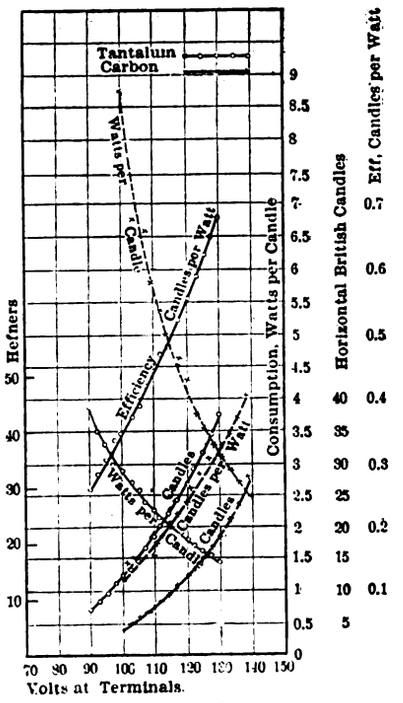

FIG. 2.

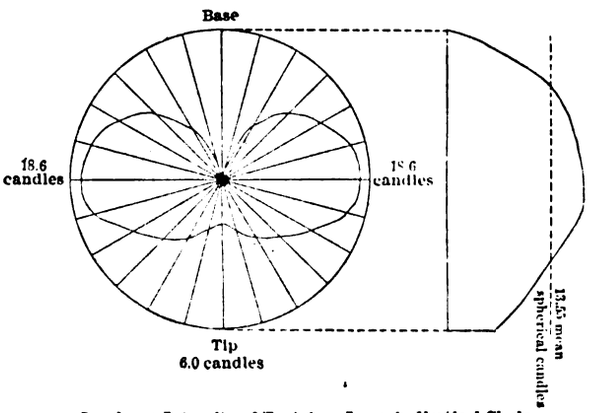
The slope of the current is greater finally in the carbon filament than in the tantalum by about one-third. This is due to the self-regulating property referred to under resistance. The tantalum lamp became appreciably luminous at a terminal E.M.F. of 9·5 volts, or about 9 per cent. of its normal working voltage. The carbon filament became luminous at 24 volts, or about 20 per cent. of its normal voltage. The curves of Fig. 2 show that the horizontal candle-power of the tantalum lamp is markedly greater than that of the carbon lamp. The luminous efficiency, or candles per watt, of the tantalum lamp is also markedly greater than that of the carbon lamp tested, frosted globes being used in each case. Thus at 110 volts the tantalum



Luminous Intensity of Tantalum Lamp in Vertical Circle.

lamp consumed 2·2 watts per candle, while at 120 volts, the normal for the carbon lamp, the latter consumed 4·3 watts per candle. The normal efficiency of the frosted tantalum lamp was, therefore, nearly double that of the frosted carbon lamp. No information is at present available as to the relative lives of the two types, but it will be seen that the general results greatly favour the new lamp.

## ARMATURE WINDINGS OF THE CLOSED-CIRCUIT TYPE.

BY WM. CRAMP.

(*Concluded from page 511.*)

CLOSED-CIRCUIT WINDINGS FOR ALTERNATORS.

**General Connections.**

It is immediately apparent that if a bipolar Gramme ring be tapped at two points at opposite extremities of a diameter, and the tappings be connected each to a separate slip-ring, that a single-phase alternating current may be taken from the slip-rings. Similarly, if two more tappings at right angles to the first two be connected to two more rings, another single-phase current differing in phase a quarter period from the former may be collected. In this way a two-phase armature is obtained.

Three tappings at 120 deg. connected to three slip-rings will give a three-phase current, and generally $n$ tappings on the winding $\frac{360 \text{ deg.}}{n}$ apart are necessary for an $n$-phase current.

This is the foundation of all rotary converters which usually have the armature winding connected down on one side to a commutator, and on the other to the requisite number of slip-rings.

The principle just explained may be applied to all those windings which have already been discussed for direct-current machines. In the general case of multiple-circuit windings, we have only to reckon the distance from the centre of one north pole to the centre of the next as 360 deg. and apply the rule given above. Of course, each slip-ring in this case will have one connection to the winding per pair of poles, so that the armature remains *multiple-circuit* from the point of view of the *alternator*, just as much as for the direct-current machine.

Similarly, a double or, generally, a multiple winding on a multiple-circuit armature may be tapped to yield an alternate current. *A tapping must be made to each slip-ring for each winding per pair of poles.* It is not uncommon to make these slip-ring connections to the commutator instead of to the actual coil, but the principle is the same. Sometimes it is not possible to give to each phase exactly the same number of inductors; but it is disadvantageous to do otherwise. Fig. 13, for instance, which has 62 inductors, would be very difficult to connect to three slip-rings; each ring would have to be connected to four points on the armature since it is four-pole and double-wound, and these connections should be regularly spaced; but in that part of the armature lying between a pair of north poles there are only $15\frac{1}{2}$ inductors in each winding, consequently we should have either to make a connection to the centre of the inductor, which is practically impossible, or have the three phases slightly out of balance. Fig. 11, for similar reasons, is difficult for three-phase, but easy enough for two-phase connections.

It will be remembered that Fig. 11 is the drum winding developed from the ring of Fig. 10. If, then, we arrange for the slip-rings in Fig. 10, we can transfer the connections afterwards to Fig. 11. Considering one phase alone, it is obvious that when the alternating electromotive force is a maximum, the connection to the slip-ring must be made to the section under the brush. Consequently for the first slip-ring of one phase we shall need connections to the pair of spirals $C^1$ and D, and to those diametrically opposite, E and F; and for the other ring of the same phase we shall need connections to G and H and K and L. So that for a single-phase current alone we require eight connections, four to each slip-ring. Of course, had there been a single winding and a four-pole multiple-circuit machine, four connections per phase (two per slip-ring) would have sufficed. Passing to the connections for the other phase, it is clear that these must be made midway between the connections of the first pair of slip-rings; so that to one ring of the second phase will be joined $A^1$ and B, M and N, to the second ring of the same phase P and Q, R and S. These tappings might easily have been made from the commutator.

In the corresponding drum we commence by selecting such an inductor as A (Fig. 11) to represent A in Fig. 10, and we remember that one spiral of the ring armature is represented by two inductors on the drum, so that we simply have to count round from A; and where connections have been decided upon for the ring, there will they be marked on the drum. Assuming that the slip-rings are to be put at the opposite end of the armature to the commutator, we obtain $C^1$ and D, E and F, for the connections to one ring, and G and H, K and L, for the other ring of the same phase. The letters $A^1$ and B, P and Q, R and S, E and F, correspond to the same letters in Fig. 10.

Since there are in all four equally spaced slip-rings, and to each ring there are four connections in pairs, it follows that having chosen any two neighbouring inductors not in the same winding for the first two connections, the correct places for the others are spaced with a number-pitch of 8 reckoned continually forward.

We then get this rule for connecting slip-rings to a multiple-circuit drum.

If $r$ be the number of rings, $w$ the total number of inductors, $m$ the number of windings, $p$ the number of poles, choose any $m$ neighbouring inductors, one in each winding, to be connected to the first ring. Then the other connections to that ring are taken with a number-pitch of $\frac{2w}{p}$ from these.

The connections to the next of the $r$ rings will be made from each winding at a number-pitch $= \frac{2w}{rp}$ from the corresponding connection of the first ring, and so forth for each slip-ring. Thus, in Fig. 11, if connections $A^1$ and B are decided upon for the first connection to the first ring of a two-phase machine, the next connections to the same ring will occur at a pitch $\frac{2w}{p} = \frac{2 \times 64}{4} = 32$ from $A^1$ B. This will be found to give the connections N and M. Similarly, the first connections to the second ring will occur at a number-pitch $\frac{2w}{rp} = \frac{2 \times 64}{4 \times 4} = 8$ from $A^1$ and B.

It must be remembered that a two-phase machine requires four slip-rings, and therefore might be more correctly styled a "quarter-phase" machine.

The slip-rings are in a multiple-circuit winding connected to each winding at each pair of poles. This is seen from the example just taken (Fig. 10) to be absolutely necessary, since because the winding is closed, there must always be at least two circuits on the alternate-current side; while, on account of the connection of the winding in the multiple-circuit type, there will be as many pairs of circuits as pairs of poles

Digitized by Google

for each winding. This is exactly in accordance with what has been already explained for the direct-current forms of these armatures, and therefore we need not dwell longer on it here.

**Ratio of Electromotive Forces in Direct and Alternate Current Armatures.**

The maximum electromotive force which can occur between any two slip-rings is the same as that which exists between the brushes for a similar continuous-current winding when they are properly set. This naturally is the peak of the alternate-current wave, and its ratio to the root mean square value of the wave is 1 : 0·707 : consequently any armature giving, when arranged for continuous current, 200 volts will for alternate-current work as a single-phaser give 141 volts. This ratio is quite independent of the number of windings or their connection, and therefore holds equally for multiple and for two-circuit windings.

**Connection of Slip-Rings to Two-Circuit Windings.**

The same reasoning applies to the case of two-circuit armatures, modified only in virtue of the fact that for each winding there are never more than two paths through the armature, and consequently there is never more than one connection per ring per winding. As an example, we may take Fig. 14, in which, for a single-phase current, connections would have to be made to two such inductors as 18 and 4, and they might be arranged at E and F as shown in the figure: the potential difference between the two positions varying, as the armature rotates, between a maximum and zero. This armature, having 18 inductors, is not easily arranged for two-phase connections; but by dividing the inductors in *order of their connection* into three equal groups (which may easily be done from Fig. 16) we arrive at three connections, such as E, M, and L, which would be the tappings necessary for a three-phase current. It is thus seen that, if from this armature we wish to take *either* single-phase *or* three-phase current, we need four tappings and four slip-rings. In multiple-wound two-circuit armatures one tapping per ring per winding is required; so that if we were to use the armature of Fig. 22 for single-phase work we should connect one slip-ring to A and $A^1$ and the other to B and $B^1$, since the inductors connected to either of these pairs lie one in each winding. No difficulty can occur in finding connections on these two-circuit armatures if we set out the inductors as in Fig. 16 for each special case.

**Frequency given by these Windings.**

Although the multiple-circuit winding remains a multiple-circuit for alternate-current work and the two-circuit remains two-circuit, yet this does not interfere with the fact that any section of the winding lying between two slip-rings undergoes in every revolution as many periods as there are pairs of poles to the machine. Thus, whether the armature is multiple or two circuit, the frequency is the same, provided that the speed and number of poles is the same. The frequency is given by $f = \frac{n p}{2}$, where $n$ = revolutions per *second* of the armature, $p$ the number of poles.

**Conclusion.**

Although throughout this exposition of the laws governing the usual forms of modern closed-circuit armature windings many points have been passed over which might have been enlarged upon, yet we feel certain that if, instead of making a blind use of winding tables, the designer refers his difficulties with multiple-circuit windings to a corresponding ring diagram, and his troubles with two-circuit windings to our corresponding development (like Fig. 16), a more complete understanding and increased self-confidence is likely to result. It is surely far better to remember how to derive formulæ and check the result, than to depend upon having a particular set of tables always in the right pocket.

## THE POWER PLANT OF A MODERN RAILWAY TERMINUS.

### The Terminal Railroad Association of St. Louis Union Station.

**To the casual observer the design and equipment of a railway terminus power station presents problems of no greater difficulty than are ordinarily encountered in the usual power plant. Upon closer examination, however, there is found to be a marked difference. In the one, a single definite service is contemplated, one subject to large fluctuations and rapid increase; while in the other, multifarious needs of widely diverse character must be provided for. Furthermore, interruptions of service must be diligently guarded against, for they so seriously interfere with the operative functions of the establishment as to render valuable almost any reasonable preventive. Not long ago an exemplary power plant was placed in operation in St. Louis, U.S.A., for serving the entire terminus properties of the Terminal Railroad Association, which controls transcontinental as well as other traffic centering in St. Louis. Only in 1902 was the enlargement of the terminus decided upon, but within the short time preceding the opening of the exposition it was to a great extent remodelled, and now ranks among the largest of the world. The magnitude of the undertaking can only be appreciated by a careful study of the service conditions and the present equipment, which are briefly outlined in the following, although but one branch of this subject—the power station—has been selected for full treatment.**

**The present terminus comprises a long principal building containing the station proper and executive offices; a hotel fronting on Market-street; a 32-track five-arch train shed extending for a distance of 880ft. to the rear; a number of express, baggage, and mail buildings; signal towers situated in the middle of the train yard, controlling the two groups of throat tracks; and a power-house placed at one side of the property. A short distance from this site are situated engine-houses, transfer tables, and a coaling station. The reconstruction work comprised the enlargement of the train shed; the rearrangement of old and erection of new baggage, express, and mail buildings; the construction of a new power-house; the building of a baggage transfer subway and of main branch subways connecting the power-house with the main and the several subsidiary buildings; the provision of an underground baggage transfer system, operated by 39 hydraulic elevators; and a Gray telautograph system for transmitting and recording train signals. The power for the above hydraulic elevators, and also that for the operation of the pneumatic system for transferring baggage checks between the main building and the railway, is supplied entirely from the power-house.**

SERVICE.

**The extreme diversity of service rendered by the present power-house equipment may be appreciated from the following enumeration, from which it will be seen that the operation of the entire terminus is largely dependent upon that of the power plant, from the heaviest power supply down to the small amount of current required for the signal and telautograph systems.**

**_Electric Lighting._—Arc and incandescent, alternating current = 1,100 primary pressure: main station building; train shed; mail building; five express buildings; coaling station; three engine-houses; three switch-houses.**

Digitized by Google

*Electric Power.*—Alternating current, 1,150 volts, main distribution system; direct current, 500 volts elevator, and fan motors; direct current, 50 volts, signal systems, train lighting; main station building; three electric elevators, direct current; ventilating fans for hotel and station; exhausters for ventilation; dish-washing machinery.

*Switch and Signal System.*—Motor-generators.

*Train Lighting, Battery Charging.*—Motor-generators.

*Telautograph System.*—Motor-generators.

*Mail Building.*—Two elevators.

*Express Buildings.*—Sixteen elevators.

*Power-House.*—Coal crusher, coal elevator, and conveyor.

*Sixteenth Street Shops.*—Various motors.

*Three Engine-Houses.*—Various motors.

*Four Transfer Tables.*

*Coaling Station.*—Coal crusher; coal elevators and conveyor; ash and cinder elevator; green sand elevator and conveyor; dry sand elevator and conveyor; car puller.

*Compressed Air.*—Switch and signal system; car cleaning; air suction, 76-tube pneumatic check transfer system.

*Steam.*—High pressure for power-house machinery, 150lb.; car heating in yards, 60lb.; steam to kitchen; occasional building heating; exhaust steam for building heating.

*Water.*—General water supply; fire protection system; high-pressure system for 39 4,000lb. baggage elevators.

## Equipment.

If there is one feature of the power equipment which may be termed characteristic, it is that of duplication of important functions. This has not been carried to the extent of extreme complication, but rather to a point where in the light of past experience the advantages derived have been found to give the greatest insurance against breakdowns with least complication. Thus the generators, exciters, rotaries, air-compressing systems, pumps, and heaters, are installed in duplicate or multiple. Shut-downs from piping failures are insured against by sectioning, and duplicate feed piping is provided. Further, automatic or semi-automatic systems and labour-saving devices are largely used in order to reduce to a minimum the work of the staff and the cost of operation. Thus lubrication is accomplished by gravity systems; coal is fed to the boiler furnaces by mechanical stokers with gravity fuel feed; and both coal and ashes are handled by power-driven machinery. The selection of the machinery and the general design of the plant was influenced by the special, rather than the general, requirements of the installation. For example, the plant was equipped with non-condensing engines, not only because no condensing water was available, but also on account of the fact that the exhaust steam would be highly convenient for heating purposes in the buildings, doing away with the necessity for live steam except in the coldest weather. For the same reason steam-driven auxiliaries are largely used, the exhaust steam being either returned to the feed-water heater or in part to the steam heating system.

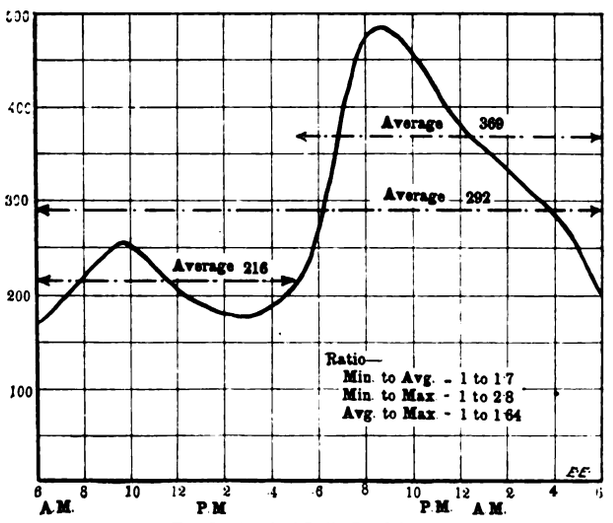

FIG. 1.—Typical Daily Load Curve.

## Electrical Equipment.

Owing to the necessity for variable speed motor drives in the electric elevators a direct-current supply was preferable, but the main distribution system for lighting and general power covers so large an area that polyphase alternating current was adopted for the main current supply of the station, and in this manner the lowest possible distribution loss for the system as a whole secured. The direct-current supply is furnished through the medium of rotary converters controlled from the main switchboard, while the alternating-current load is handled by individual feeders directly at generator potential—viz., 1,100 volts. In spite of the diversified service, the composite electrical load upon the plant resembles very closely that of the usual central station, with the exception of a higher all-day average in comparison with the peaks. This is shown by the load curve (Fig. 1) for July 5, 1904.

## Compressed-Air Service.

An idea of the importance of this section may be gained by the following facts relating to the signal system. For controlling the various switch movements 503 air-cylinders are required, each taking from ·06 to 1·5 cubic feet of free air per stroke. Each train entering the station occasions from three to thirty or more switch movements, averaging 15. During July the train movements averaged 496 trains per day, totalling 2,193 cars, but during the rush hours a maximum of 158 trains per hour was observed, which is equivalent to one every 23 seconds. Compressed air is also largely used for cleaning car cushions, for which purpose outlets are provided at numerous points where hoses may be attached.

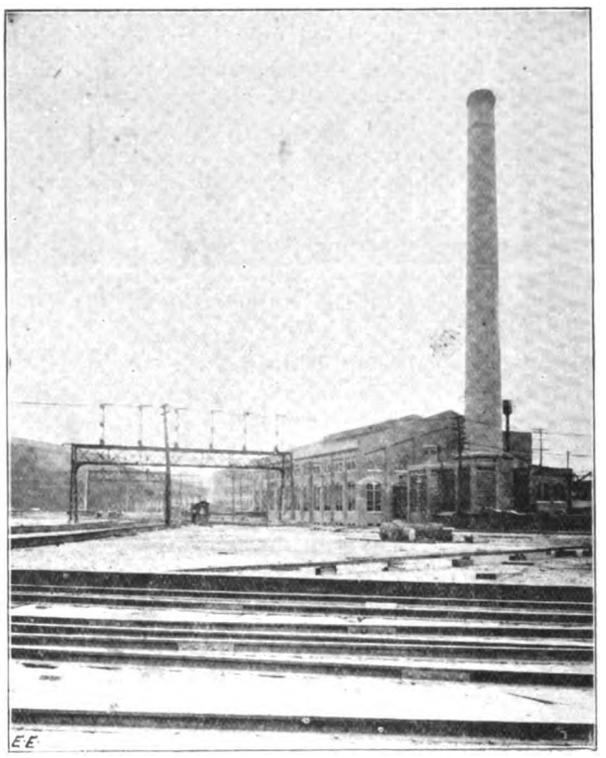

FIG. 2.—General View of Power Station.

## Power-House Building and Distribution Tunnels.

The accompanying illustration (Fig. 2) gives a general view of the power-house. From this building a subway extends to the left, where it turns at right angles, continuing down the centre of the train shed, with other branches to the express buildings. This main tunnel aggregates 700ft. in length, is 12ft. in width, 9ft. in height, and of concrete construction, with steel roof beams. The power-house building has been rendered fireproof throughout by the use of concrete-steel construction, tile roof, steel roof trusses, and concrete-steel coal and ash bins. For all supported flooring, reinforced concrete arches are used, and solid floors are surfaced with concrete. At the rear end of

Digitized by Google

the boiler-room is situated a small pump-house addition, containing heaters, feed pumps, and fire pumps, and outside the building, opposite the coal elevator, is an elevated ash-storage bunker, placed directly over the spur track paralleling the building wall, so that coal may be unloaded and ash loaded from one position of the hopper car.

some vacant space for extensions. The generating units alone occupy less than 19 per cent., including liberal passageways, or 1·35 square feet per electrical horse-power.

### Details of Boiler-Room Equipment.

The accompanying illustration of the boiler-house (Fig. 8)

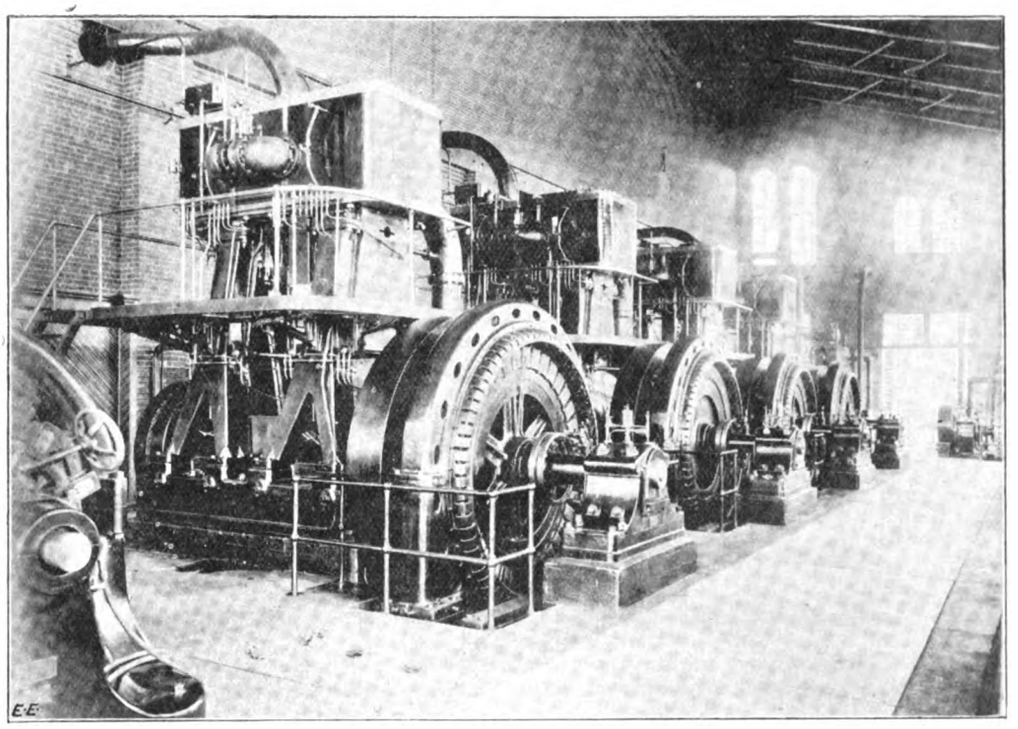

Fig. 3.—Front View of Main Power-Generating Units.

The power-house occupies a total of 13,660 square feet inside the walls, of which 53 per cent. is devoted to the boiler plant and 34 per cent. to the electric power machinery, the remainder, 13 per cent., being occupied by the compressors. This is equivalent to 1·8 square feet per electrical horse-power for the electric power equipment and 2·62 square feet per boiler horse-power for the boiler plant. The 34 per cent. includes the floor space necessary for generating and exciter units, rotaries, switchboards, and

shows the general arrangement. The two Babcock and Wilcox boilers in each battery are suspended from a structural framework free from the setting. At the front independent supporting columns are not used, the drums being hung from gusset plates riveted to the longitudinal girder supporting the side wall of the coal bunker. The stokers are of the well-known Roney inclined rocking-grate type with coking arches, which assist in gasifying the green fuel, thus preventing smoke. They are operated by two small

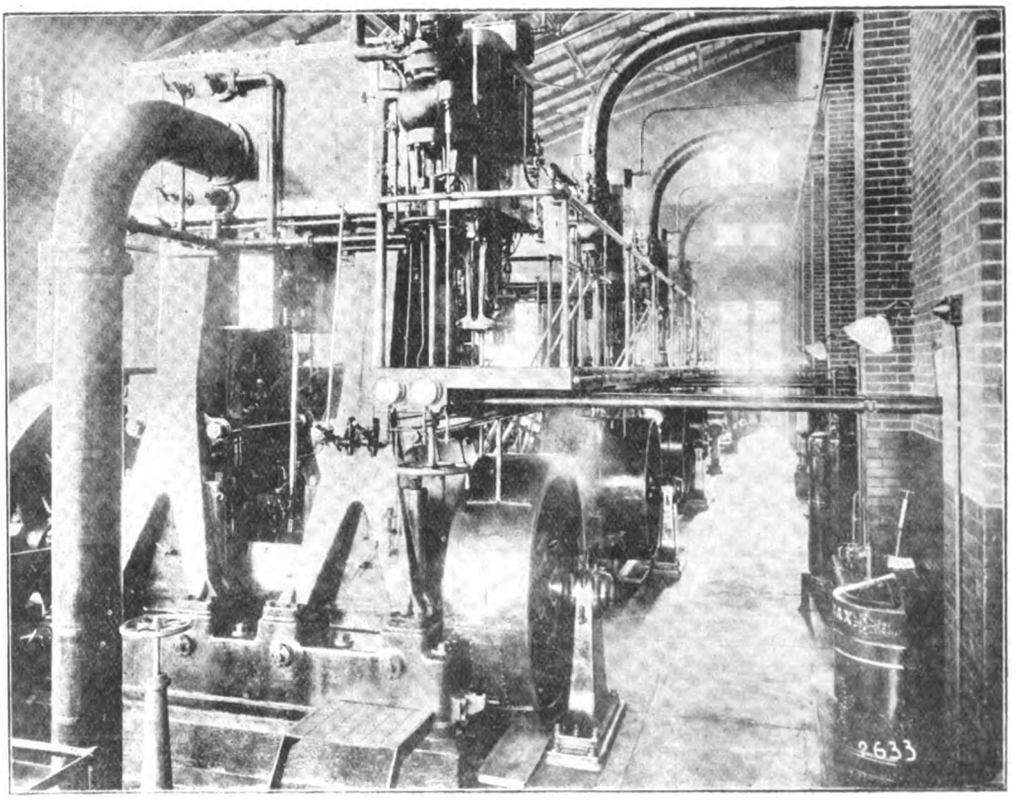

Fig. 4.—Rear View of Main Power-Generating Units.

Digitized by Google

"Standard" engines, each of which normally works half of the stoker equipment, although couplings are provided in the line shaft so that their connections may be interchanged if necessary. Coal is fed by gravity from the bunkers above, being conveyed by shoots (as shown) to the hoppers. These shoots may be swung back when the boilers are to

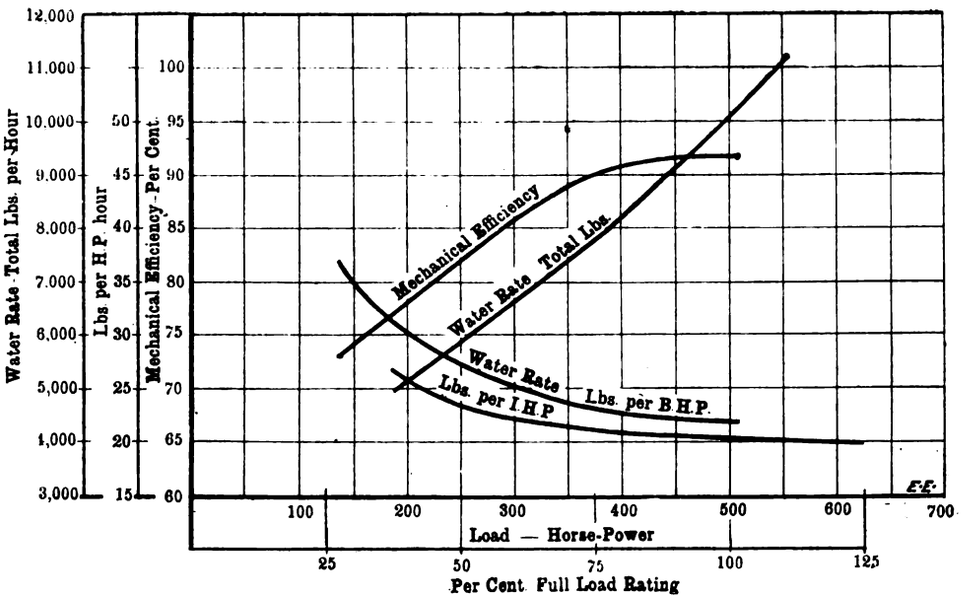

FIG. 5.—Performance of a 500-h.p. Westinghouse Marine Type Compound Engine (non-condensing).

be cleaned, at which time the gates at the top are used to shut off the coal supply. Ordinarily they are left open. A single vertical conveyor handles both ash and coal, which is distributed by a deflecting gate at the top, the ashes gravitating to the ash bunker outside and the coal to the belt conveyor traversing the length of the coal bunkers. Ashes drawn from the stoker pit are conveniently transferred by means of Koppel cars to a hopper in the floor communicating with the elevator boot, and covered by a cast-iron grating. Coal may be delivered from the hopper cars either through the crusher or not, as is desired, and provision is also made for receiving coal from wagons. In order to manipulate one or several trucks standing upon the siding without the assistance of a locomotive, a steam-driven winch is used, placed, as shown in Fig. 9, at the end of the boiler-room. A cable from this winch extends for some distance into the yard and round a pulley, doubling back along the building wall for such a distance as may be necessary to pick up the car in question. A considerable saving in the quantity of water required for boiler cleaning is made by returning the dirty water to a sump well through floor gutters. After settling, the water is skimmed while overflowing into a tank, from which it is again pumped to the boilers. By this means the entire row of 10 boilers may be washed with one change of water.

*Piping.*—Two steam mains extend the entire length of the boiler-room, one a 12in. header and the other a 6in. auxiliary. The main header is sectionalised by valves between each battery and at the centre, while the auxiliary is sectionalised only at the latter point. The mains are tied together at both ends and also near the centre. Main engines, exciter engines, air-compressors, and hydraulic pumps are ordinarily supplied from the main header; but in cases of accident one exciter, one compressor, and the hydraulic pumps may be driven from the auxiliary main. Combination globe-check valves in the boiler risers prevent back flow of steam in case of accident to any one boiler. The entire pipe system is suspended from the roof trusses, long runs being anchored at the centre; and in the case of branches, necessary lateral flexibility is secured by 6in. lengths of screwed pipe at the junction with the mains (see Fig. 9). The auxiliary main is fed by 2in. connections with its checks and valves tapped directly into each boiler header. This practically debars the possibility of steam supply being entirely shut off from the high-pressure system. Water-pockets are purposely formed at the ends of each steam main, which are drained by a steam loop and Holly gravity return system. This system also drains all valve pockets, engine throttles, and the entire high-pressure system of piping, the drips being automatically returned to the boilers by the differential pressure of the system. All important valves may be operated from iron galleries supported from the roof, as shown. These are 24in. wide, and are constructed of flat iron bars set on edge with 1in. spacing. Iron ladders and stairways of equally substantial construction are also used throughout the boiler-room. Steam due to boilers blowing off is prevented from escaping into the boiler-room by a conical discharge main connected to the several safety valves. This main varies from 4in. to 12in. in diameter, and runs the entire length

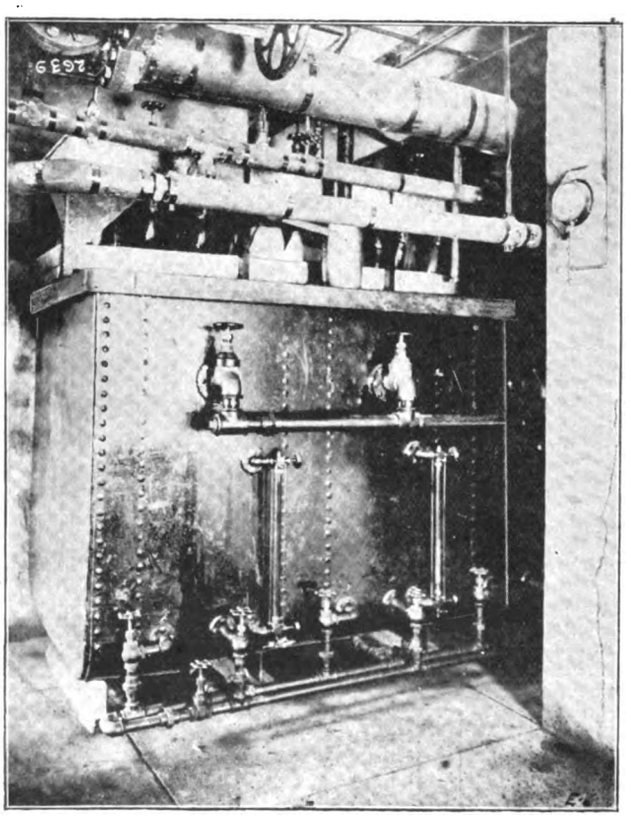

FIG. 6.—Oil Filters.

of the boiler-room, paralleling the other mains as shown in Fig. 9.

Unusual precautions have been taken in ensuring against interruptions of feed water. Two duplicate 6in. feed mains extend along the roof of the ash tunnel parallel with the boiler fronts. At each battery two 2½in. risers form a loop from main to main, with branches to the boiler drums.

Digitized by Google

This arrangement, shown in Fig. 8, enables the feed for either boiler to be drawn from either main. The main exhaust line, a 16in., 18in., 20in. conical main, rests directly upon the engine-room basement floor, and discharges into the heating system at one end through a 20in. Cochrane separator, which removes the greater part of the oil from the steam used for heating purposes, and into the feed-water heaters at the other. This exhaust system, likewise the feed piping and heaters, are covered with magnabestos insulation. During cold weather the exhaust steam may be supplemented by live steam from two sources, a branch from the end of the main header, and an extension of the pump line, which latter may either be supplied from the main or the auxiliary steam line.

### Details of Engine-Room Equipment.

The main power generating units are well illustrated in the accompanying illustration (Figs. 3 and 4). Four units are at present installed, each of 500 h.p. normal capacity, and a blank steam connection has been provided for a fifth unit should it be found necessary to instal one in the future. The engines are of a type specially developed by the Westinghouse Machine Company for power station work—a medium power, high speed, compact, and efficient engine, and one well suited to this particular service. The general data of the engines are as follows: over-all dimensions—length 10ft. 2in., height 13ft. 10in., width 6ft. 6in.; cylinders—high pressure 17in. diameter, low pressure 27in. diameter, stroke 24in.; revolutions per

not over 16·7lb. per indicated horse-power. A few features of construction are of interest.

It will be observed that the continuous bed-plate is not used for the entire unit, but that engine, generator, and outboard bearings are supported by separate concrete piers built up from the common foundation. The bed-plate, which is of the heavy box type, is designed so that the three crank pits may serve as oil-wells to collect all oil drips, which are then conveyed by pipes to a filter and returned to the oil reservoir. Each bearing may be adjusted from the outside of the bed-plate by the wedge bolts shown in the illustration. By removing the cap and easing off the bearing wedge, the lower shell may be slid out on top of the shaft for inspection. A coupling on the crankshaft placed between the two cranks permits of the removal of the shaft without dismantling the engine.

All of the four engines are inter-connected by a cast-iron gallery, which also surrounds three sides of each of the units at a height convenient for getting at the throttle and lubricators. Each engine may thus be controlled from this gallery or from the floor, as may be most convenient. The exhaust pipe of the engine is fitted with a pedestal valve, shown at the left side of Fig. 4, so that the engine may be operated from one position. A small by-pass upon the main throttle valve provides for warming up the engine previous to starting, and a similar by-pass around this

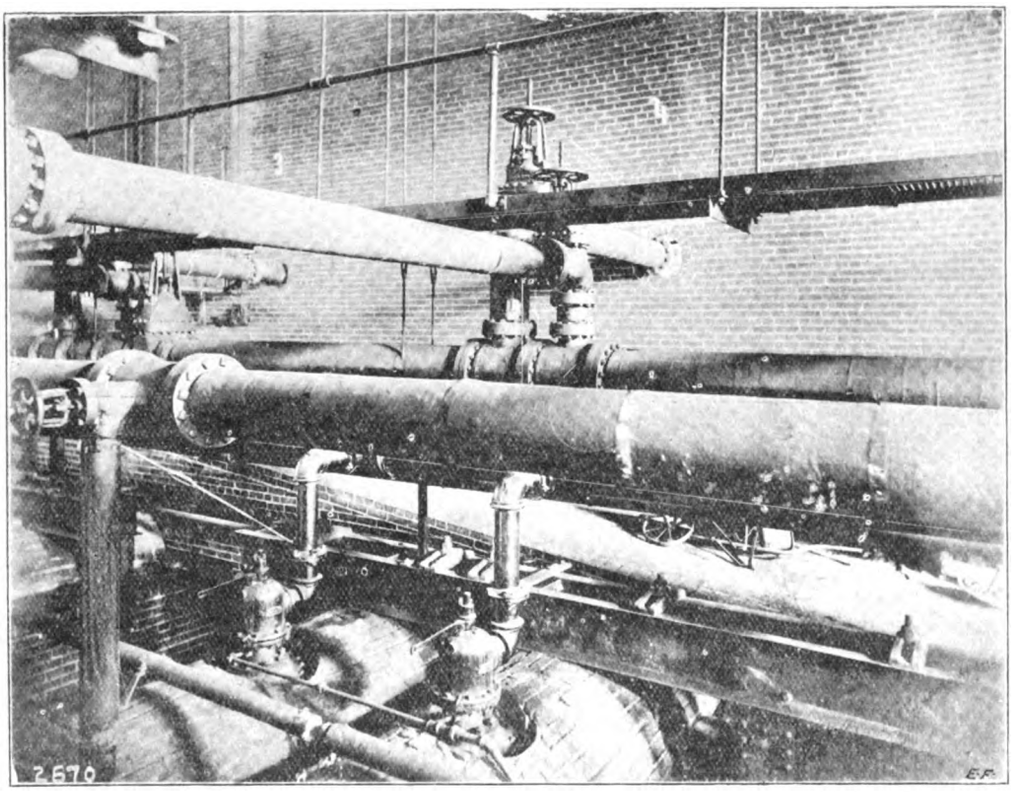

FIG. 9.— team Piping above Boilers, showing Main and Auxiliary Steam Line and Safety Valve Discharge Line.

The engines are capable of sustaining a continuous overload of 25 per cent. with a maximum of 750 h.p., or 50 per cent. for short periods. They were, of course, designed for non-condensing operation, having a cylinder ratio of only 1 to 2½. The speed is controlled by an automatic inertia shaft governor mounted within the flywheel at the throttle side of the engine. An economy of 20lb. of steam per indicated horse-power at full load has been obtained during tests conducted upon an engine of this size and type before leaving the works. These results are shown in the accompanying tables and curves (Fig. 5) It is of interest to note that the results shown have been obtained without infinitesimal clearances, valve arrangement, automatic low-pressure cut-offs, steam-jackets, receivers, or any of the refinements that are generally supposed to be responsible for economic performances. As a matter of information only, a series of condensing trials were run. Although obviously out of its element, the engine showed a steam consumption of 16·2lb. at a load of 430 i.h.p., and at all loads ranging from 300 h.p. to 550 h.p., pedestal valve into the exhaust main allows the drip and condensed steam to be carried off while the engine is idle without manipulating the large exhaust valve.

*Oiling System.*—One of the features of the power plant is the complete manner in which the lubrication of the machinery is taken care of by automatic means. In the case of the engine oil, a simple gravity head is depended upon to insure a constant supply. Two 500-gallon tanks are situated upon an elevated gallery in the boiler-room, and the height of oil in them is indicated by a gauge glass connection, shown on the engine-room wall in Fig. 3. Oil is elevated to these tanks from the filter in the basement by a small duplex pump (in duplicate), and after passing through a small cone filter of perforated metal, is delivered to a 2½in. brass oil main passing along the engine-room with branches to each engine. One of these is shown in the upper left-hand corner of Fig. 3. After reaching a small cast-iron reservoir on top of each engine, the oil descends to a main supplying the several manifolds, from which it is distributed to the various

Digitized by Google

parts of the engine through sight-feed cups. As the oil head upon the system is constant at about 15ft., an adjustment of all the feeds once made is permanent, and a single valve in the feed pipe controls the entire system at each engine. The oil filter referred to above is shown in Fig. 6. It consists of a boiler iron tank divided into three compartments by baffle plates, these compartments being partly filled with water. Oil from the engine is first filtered through small canvas bags, 27 in number, and in passing around the baffles the remaining impurities are removed and deposited in the bottom, from which they may be drawn off at outlets provided in each compartment, as shown. A live steam connection to each compartment is used only during cold weather to maintain the mobility of the oil by heating it to any desired temperature. Cylinder oil is handled in a somewhat similar manner, except that it is under boiler pressure. A steel tank of 75 gallons capacity, and situated in the basement, is filled with cylinder oil through a funnel in the floor above, covered by a cast-iron floor grating. City water pressure introduced into this tank elevates the oil to a riveted steel tank on the engine-room floor, shown between the two pilasters in Fig 4, a check valve preventing the return when the water pressure is turned off. This tank is filled approximately once a week, and when full boiler pressure is turned on which forces the oil into a 1in. main running along the edge of the engine platform, with branches at each engine serving the throttle, receiver, cylinders, and glands. Steam pressure is taken directly from the main steam header through a pipe loop, carried up to the height of the roof trusses in the boiler-room and back to the oil-tank. This pipe loop is continually filled with condensed steam, and the differential pressure between boiler and throttle, combined with the static head due to the water column of approximately 20ft., ensures a good supply of oil to all parts of the engine. The automatic system does not, however, interfere with the usual methods of lubrication, as hand pumps are provided at each engine on both floor and gallery for the same purpose. The pressure tank may also be filled by hand if necessary, and the oil may be drawn off from this point through a convenient spigot. A 2½in. pipe connects with the oil filter, so that if desirable the cylinder oil may be purified in the same manner as the engine oil.

*Gauge Board.*—Another excellent feature of the engine-room is the gauge board, which is of uniform size with, and installed as part of, the electric switchboard. Upon this gauge board may be observed the operation of the several functions of the mechanical equipment as follows: boiler pressure, steam and exhaust heating, hydraulic supply and return, city water, and compressed air. All the above are indicating gauges. There are two recording gauges on the air pressure, for general uses and for the signal system. At present these services are combined, but provision has been made for separating them in case of mutual interference.

*Air-Compressors.*—The two compressors, which are of the compound two-stage type with a large intermediate receiver, deliver compressed air through independent mains to a condenser house near by. Here are installed two large air-storage tanks, automatically drained at the bottom, which finally distribute to four sets of condensers, where the air is cooled and the moisture precipitated before it is utilised in the switching system. These condensers consist of 38 vertical 2in. pipes in parallel between receiving and discharge headers. Each of the compressors has capacity to handle 2,000 cubic feet of free air per minute.

*Hydraulic Elevator System.*—The pumping machinery necessary for supplying the elevators is placed in the basement beneath the switchboards. Each of the pumps is of the duplex pressure pattern of 120 gallons capacity, and is automatically controlled by Mason regulators. One thousand gallons per hour will ordinarily be required for operating the 39 elevators. The hydraulic system is designed to stand 750lb. pressure per square inch, and either oil or water may be used. For the former, a storage tank of 14,000 gallons capacity is installed in an underground chamber connecting with the tunnel. All of the hydraulic piping is constructed with forged bends. A 6in. line conveys the high-pressure oil to the elevators, and an 8in. line returns it to the storage tank.

*Distribution.*—In the main tunnel a section, 3ft. 6in. in width, is reserved for the distributing piping and electric conduits, but only about 10 per cent. of the tunnel area is actually used. A typical section of the distributing system comprises the following: 20in. low-pressure steam for heating, 8in. heating return, 6in. steam for car heating, 4in. steam for kitchen, 6in. hydraulic supply, 8in. hydraulic return, 3in. compressed air, 27 tile cable ducts (laid in and covered with cement), telephone and signal wires. The various runs of piping in the tunnel are supported by flexible roller hangers of simple design. These consist of a short length of iron pipe hung from the roof beams by two eyebolts, and covered by a loosely-fitting pipe roller, upon which the distributing main rests. All of the pipe mains are usually anchored at approximately the middle point of straight runs. In one case, however, the length of the run has made necessary the use of a specially-designed expansion joint, which combines its principal function with that of an anchor.

### Details of Electrical Equipment.

A very complete switchboard controls the electrical system. It comprises several sections devoted to the main generators, exciters (Fig. 7), rotary converters, power and lighting feeders, and arc system. Each panel controls a single machine or feeder, which arrangement results in great simplicity, ease of operation, and absence of danger from confusion. Westinghouse type D oil switches are used on all the high-tension circuits, and small series and shunt transformers are placed in the meter circuits in order to avoid the application of high-tension current directly on the meters. The arc circuits are controlled entirely by plug switches. The generators are synchronised with the aid of a Westinghouse synchroscope mounted upon a swinging panel at the end of the board, or by the usual synchronising lamps. In breaking the generator fields the current is first shunted through an iron resistance until it has been reduced to a harmless nature, when it may be opened by the switch. The majority of the instruments are of the Westinghouse long scale, round dial type, but where confusion would be liable to result between alternating-current and direct-current meters, dissimilar designs are used.

### Operation.

The regular operating force of the power station consists of an engineer-in-chief, an assistant engineer, two engine-room and two boiler-room attendants. It is good evidence of the value of the several automatic and labour-saving appliances used in the plant that this small force of men is capable of successfully handling an equipment of such comprehensive character, where continuity of service is an item of such extreme importance. At the appointed time for transferring the power supply of the terminus from the old power-house to the new one above described, no hitch or interruption occurred, the two sets of switches being simply opened and closed respectively.

The establishment of the power plant, as well as the power reconstruction work at the terminus, has been entirely carried out by Messrs. Westinghouse, Church, Kerr, and Co., who have also acted as consulting engineers for the Terminal Railroad Association on this particular work.

## TEMPERATURE CURVES AND THE RATING OF ELECTRICAL MACHINERY.*

BY RUD. GOLDSCHMIDT, ASSOCIATE MEMBER.

*(Concluded from page 455.)*

Below an example is given to show the application of the rules just formulated. We intentionally adhere to the simple case of a field coil, only just referring to the subject of machine parts, in which we have to deal with the separate heating of copper and iron, and in which, especially before the final temperature is reached, the copper may be quite hot, whilst the iron is still cool—a subject which it is intended to deal with more fully in a separate paper. In principle there is no difference whatever in calculating the

* Paper read before the Institution of Electrical Engineers.

Digitized by Google

temperatures of field coils or armatures, induction motor stators and rotors, or transformers.

*Example.*—A continuous-current generator has a current density in the field of 1·35 amperes per mm.², corresponding to an initial increase of 0·55deg. per minute. The field coil is dimensioned so that at normal watts the temperature rise is $t\,f = 45$deg. C. = 81deg. F., total ideal heating time $T_i = \frac{45}{0·55} = 82$ minutes = 1 36 hours.

The machine is to be submitted to the following test:

(1) 4 hours normal watts.
(2) 1½ hours 56 per cent. higher watts (25 per cent. overload in current).
(3) ½ hour 125 per cent. higher watts (50 per cent. overload in current).
(4) 2 hours normal watts.
(5) 4 hours shut down.
(6) 2 hours ½ × normal watts.

What is the temperature rise $t_1$ . . . $t_6$ at the end of the different periods?

(1) $T_1 = 4$ hours normal watts.
$t\,f_1 = 45$deg. C.

$$T_1 = 4 \text{ hours} = \frac{4}{1·36} = 3 \times T_i.$$

From Table V. we find at end of period (1) the final temperature $t_1 = 0\,95 \times t\,f_1 = 0\,95 \times 45 = 43$deg. C.

(2) $t_2 = 1\frac{1}{2}$ hours 56 per cent. higher watts.
New $t\,f_2 = 1·56 \times 45 = 70$deg. C.
Initial temperature $t_1 = 43$deg. C.

Total change of rise 70 − 43 = 27deg. C. $t_2 = 1\frac{1}{2}$ hours $= \frac{1·5}{1·36} = 1·1 \times T_i$.

From Table V. we find that at $1·1 \times T_i$, $0·65 \times 27 = 17$deg. C. is reached. Temperature at the end of the second period is $t_2 = 43 + 17 = 60$deg. C.

(3) $t_3 = 0·5$ hours at 2·25 × normal watts.
New $t\,f_3 = 2·25 \times 45 = 102$deg. C.
Initial temperature $t_2 = 60$deg. C.

Total range of rise 102 − 60 = 42deg. C. ½ hour $= \frac{0·5}{1·36} = 0\,37 \times T_i$.

From Table V. we see that at $0·37\,T_i$ $0·28 \times 42 = 12$deg. C. is reached. The temperature at the end of the third period $t_3 = 60 + 12 = 72$deg. C.

(4) $t_4 = 2$ hours at normal load.
New $t\,f_4 = t\,f_1 = 45$deg. C.
Initial temperature $t_3 = 73$deg. C.

Total range of drop 73 − 45 = 28deg. C. $t_4 = 2$ hours $= \frac{2}{1·36} = 1·47 \times T_i$.

By Table V., in 1·47 times $T_i$ − $0·73 \times 28 = 20$deg. C. of cooling down. Temperature at the end of the fourth period, $t_4 = 73 - 20 = 53$deg. C.

(5) $t_5 = 4$ hours shut down.
New $t\,f_5 = 0$.
Starting temperature $t_4 = 53$deg. C.
Total range of drop 53 − 0 = 53deg. C.

The cooling when the machine is shut down is in the ratio of 2 to 3 worse than with the machine revolving. Thus our ideal heating or cooling time, $T_i$, goes up in this ratio, say to $T_i^1$. $T_i^1 = \frac{3}{2} \times 1·36 = 2·04$ hours. $t_5 = 4$ hours $= \frac{4}{2\,04} = 1·96 \times T_i$.

By Table V., in 1·96 times $T_i^1 = 0·83 \times 53$deg. C. = 44deg. C. are cooled down, and the temperature at the end of the fifth period is $t_5 = 53 - 44 = 9$deg. C.

(5) $t_6 = 2$ hours ½ normal watts.
With this reduced excitation the motor has to run faster, and in consequence the ventilation is improved, say 20 per cent.

$$\text{New } t\,f_6 = \frac{0·5 \times 45}{1·2} = \frac{22·5}{1·2} = 19\text{deg. C.}$$

Initial temperature, $t_5 = 9$deg. C.
Total range of rise, 19 − 9 = 10deg. C.

$$\text{New } T_i^{11} = \frac{1\,36}{1·2} = 1·13 \text{ hours.}$$

$$T_6 = 2 \text{ hours} = \frac{2}{1·13} \times T_i^{11} = 1\,78 \times T_i^{11}.$$

By Table V., in 1 78 times $T_i^{11}$, $0·8 \times 10 = 8$deg. C. are reached. The temperature at the end of the sixth period is $t_6 = 9 + 8 = 17$deg. C.

## IV.—Crane Rating.

These investigations are of great importance in the design of machines which are only on full load for a few hours, such as lighting transformers, and machines which require an overload for an hour or two. In such cases the time during which the load is on can generally be determined with tolerable exactitude, and for dealing with this problem our next examples give full information. This kind of rating is often called the "short-time rating," from which we have to distinguish machines which are designed for intermittent use for short periods of application and interruption (of a few minutes), briefly called "crane rating." This latter kind of machine is quite distinct from a machine designed for short periods of use and long interruption, which we dealt with in the first part of our study.

The characteristic qualities of crane rating are as follows: (1) The load has a more or less regular periodic character. This distinguishes crane rating from the short-time rating. (2) The time of use and the time of interruption is so short that during the former the temperature obtained does not come anywhere near the final temperature, and during the time of interruption the apparatus does not cool down to anywhere near the air temperature. In fact, after some hours' run the maximum and minimum temperature attained must remain within a few degrees per cent. of the average temperature.

We will first assume that the cooling conditions when the machine is shut down are the same as when the machine is running, and study the question of crane rating on our field coil, the data for which are:

Current density 1·35 amperes per mm².
Final temperature for continuous run, 50deg. C.

As we found from the current density, the initial rise is 0·55deg. per minute, and the ideal heating time $T_i = \frac{50}{0\,55} = 90$ minutes = 1½ hours. If we submit the coil to a crane load, consisting of periods of three minutes' heating and seven minutes being shut down, the total period lasting 10 minutes, then in order to obtain the average temperature curve round which the actual temperature fluctuates, we have only to consider that a heating time of three minutes is followed by a cooling time of seven minutes. Since during these short spaces of time the temperature increase or fall in the unit of time can be considered constant, the seven minutes' cooling is as effective as a three minutes' cooling with $\frac{7}{3}$ times increased intensity. To find the final average temperature we have only to multiply the final temperature for continuous run, 50deg. C. by $\frac{3}{10}$, and so obtain $\frac{3}{10} \times 50 = 15$deg. C.

Considering that three minutes is 3/90 = 3·3 per cent. of the ideal heating time, and that in the short times of three and seven minutes the time and temperature (taken as percentages) are practically proportionate to one another, the positive temperature fluctuation during three minutes (see Table V.) is 0·033 × total range of temperature = 0·033 × (50deg. − 15deg.) = 0 033 × 35deg. C. = 1·15deg. C. The negative fluctuation during seven minutes is 0·077 × total range of drop = 0·077 × (15deg. − 0) = 1·15deg. C. Consequently the final temperature is 15deg. C. $\pm \frac{1·15\text{deg. C.}}{2}$

The average initial rise is $\frac{3}{10} \times 0·55 = 0·165$deg. C. per minute, so that the ideal heating time is $\frac{15}{0·165} = 90$ minutes, the same as with continuous rating. Thus the crane motor requires the same time for heating up as the machine

Digitized by Google

designed for continuous rating. The final temperature is directly proportional to the ratio,

$$\frac{\text{time of use}}{\text{time, full period}}$$

under the assumption that when the machine is shut down the ventilation is the same as when it is running.

As stated above, the cooling is much worse while the machine is shut down, because we considered that a reduction of the ventilation of the field coil in the ratio of two-thirds would occur. Taking this into account, we have three minutes' heating, three minutes' cooling with full intensity, seven minutes' cooling with two-thirds of full intensity, which is equivalent to

$\frac{2}{3} \times 7 = 4{\cdot}7$ cooling with full intensity.

Total equivalent time of cooling with full intensity $4{\cdot}7 + 3 = 7{\cdot}7$ minutes.

Final temperature $\frac{3}{7{\cdot}7} \times 50 = 0{\cdot}39 \times 50 = 19{\cdot}5$deg. C.

The ventilation of the *armature* is, at full speed, three to five times better than when it is stationary, so here we have three minutes' heating, three minutes' cooling with full intensity, seven minutes' cooling with, say, one-quarter of full intensity, equivalent to $\frac{1}{4} \times 7 = 1{\cdot}8$ minutes' cooling with full intensity. Total equivalent time of cooling with full intensity $= 3 + 1{\cdot}8 = 4{\cdot}8$ minutes.

Final temperature $\frac{3}{4{\cdot}8} \times 50 = 0{\cdot}63 \times 50 = 31$deg. C.

If an ordinary continuous rating motor is to be used as a crane motor, the losses in the badly-ventilated parts (field coils) can be increased considerably more than in the well-ventilated ones (armature). This only holds good if the machine is to be designed for actual crane-working conditions, the time of working and stopping being definitely given.

Usually a crane motor has to stand a one hour's test on full load, independently of what it has to do in actual practice. It is naturally very much simpler to carry out a test of this kind than a test in which the motor has to be alternately switched on and off. It is even an easier test than a continuous rating test. This is the chief reason why we adhere to the one hour's test, and long experience in actual practice has proved that in nearly every case a motor which stands this test with a moderate temperature rise is large enough for crane work. One disadvantage, however, is seriously felt—namely, that the time of test is the same for small as well as for large machines—and still more that the time is the same for open and totally enclosed ones.

Applying the formula for $T_i$, we find that for a 2-h.p. motor the ideal heating time of the field is about one hour, and of the armature six hours, therefore in one hour 63 per cent. and 80 per cent. respectively of the final temperature is reached (Table V.). In the case of a 50-h.p. motor, the ideal heating time of the field is, say, 12 hours, that of the armature 75 hours, and thus the field has in one hour attained 56 per cent. and the armature 75 per cent. of the final temperature.

Now, under a certain condition of crane work, given by the load factor $= \frac{\text{time of working}}{\text{total period}}$, the machine reaches a temperature which is quite in proportion to that which we have called the final temperature, and which would be obtained if the machine ran continuously with its crane brake horse-power. Taking the ventilation, with the machine at rest, to be two-thirds in the case of the field, and a quarter in the case of the armature, of that when the machine is at full speed, the one hour's test corresponds:

| | | | | | | |
|---|---|---|---|---|---|---|
| In the field of the 2-h.p. motor to a load factor of | | | | | 60 | per cent. |
| ,, armature | ,, | 2 | ,, | ,, | 50 | ,, |
| ,, field | ,, | 50 | ,, | ,, | 47 | ,, |
| ,, armature | ,, | 50 | ,, | ,, | 42 | ,, |

In the case of totally-enclosed machines, taking the ventilation when the machine is at rest as 0·8 for the field, and for the armature half of that of the machine when at full speed, the one hour's test would mean approximately

| | | | | | | |
|---|---|---|---|---|---|---|
| In the field of the 2-h.p. motor a load factor of | | | | | 38 | per cent. |
| ,, armature | ,, | 2 | ,, | ,, | 38 | ,, |
| ,, field | ,, | 50 | ,, | ,, | 31 | ,, |
| ,, armature | ,, | 50 | ,, | ,, | 31 | ,, |

Thus we see that the one hour's test is more severe on small and open machines than on large and totally-enclosed ones. Considering a one hour's crane test to be correct (load factor, say, 50 per cent.) for small open-type machines, the time of test ought to be:

| | |
|---|---|
| For large open-type machines, say | 1½ hours. |
| For small totally-enclosed machines | 1½ ,, |
| For large ,, ,, | 2 ,, |

Naturally, a difference would also come in for different speeds and different percentages of cotton in the field coils, but we cannot consider this question on the present occasion.

Our investigation as to the meaning of the one hour's crane test shows that its simplicity involves a very great inequality, having a different value for every single machine. It would be desirable, therefore, to find a test which would give accuracy as well as simplicity. A test with the exact conditions given, for instance, with a period of three minutes' running and seven minutes' stopping is, however, somewhat troublesome.

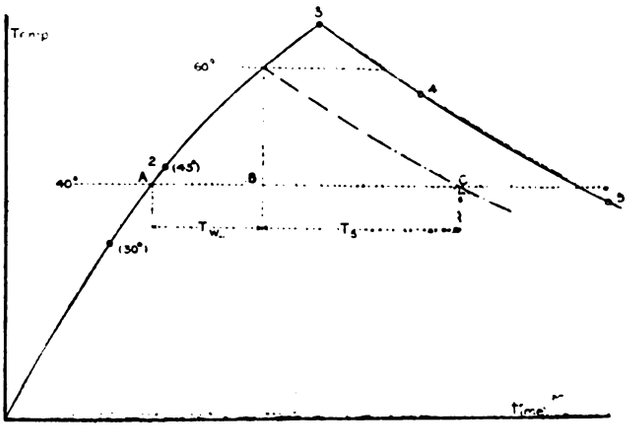

FIG. 20.

Now, within rather wide limits, the temperature curve can be considered a straight line, and in consequence the temperature is only dependent on the load factor. Therefore we could replace the three minutes' running and the seven minutes' stopping by saying nine minutes' running and 21 minutes' stopping respectively, which would require less attention than the shorter period. We could extend the length of the period a little further still for large machines, and shorten it a little for small machines. This "crane test with extended periods" certainly gives more exactness than the one hour's test, and enables us to make the expression "crane rating" more definite, and to allow for different load factors. The following is suggested as a simple method of crane-motor testing. The final temperature of a crane motor depends (1) on the load (brake horse-power; (2) on the load factor, $\frac{\text{time of working}}{\text{total period}}$.

With an ordinary machine for continuous rating we have only to consider two figures—viz, the load and the temperature rise. In the case of the crane machines a third is added—viz., the load factor. Having to deal with three figures, instead of asking, "What will be the final temperature at a given load and load factor?" we can reverse the question, and ask, "For how many minutes out of 10 can the motor give a certain output if the temperature rise is not to exceed 50deg. C.?"

The answer to the latter question can be very easily supplied by a test. When a crane motor has reached its final temperature, the temperature increase (during the working period, *a b*, Fig. 20) is exactly equal to the temperature drop during the stopping period, *c d*. If, therefore, we take the temperature curve of the motor on full load up to a little more than 50deg. C, or to 60deg. C., and carefully observe the time, T *w*, required for the rise from 40deg. to 60deg. C. (Fig. 21), then if we shut down the machine and observe the time required for cooling down from 60deg. to 40deg. C., T *s*, the load factor is given by the ratio—

Digitized by Google

$$\frac{\text{Heating time}}{\text{Heating + cooling time}} = \frac{t\,w}{\mathrm{T}\,w + \mathrm{T}\,s} = \frac{\mathrm{A\,B}}{\mathrm{A\,C}} \text{ (Fig. 21).}$$

It is very easy to take this test for all stationary parts to which a thermometer can be left attached during the working period. For the armature one could stop, say, half-hour after starting, take the temperature at that moment (point 1, Fig. 22), and easily judge in what time the 40deg. rise will be approximately reached. At the end of the period stop again, take the actual temperature, which need not necessarily be exactly 40deg. C. (point 2, Fig. 22), run on again for some time until 60deg., or a little more, are reached (point 3, Fig. 22), and then finally stop to observe the cooling of the armature (points 4 and 5).

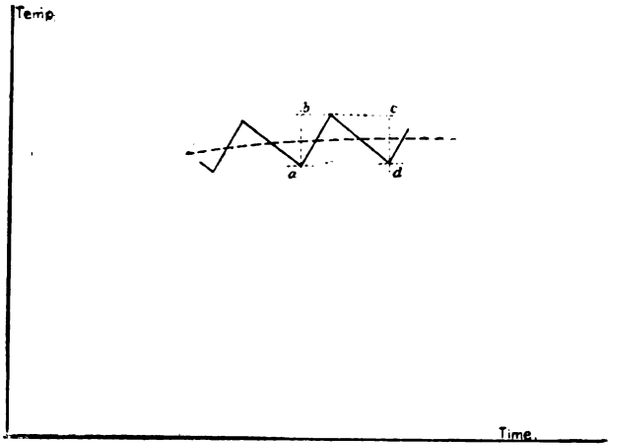

FIG. 21.

If point 3 does not coincide with 60deg. C., we transfer the cooling curve horizontally until it passes the 60deg. point (dotted curve, Fig. 22), and draw the horizontal line, A C, through the 40deg. point, then $\frac{\mathrm{A\,B}}{\mathrm{A\,C}}$ is the load factor.

If the temperatures are taken with a thermometer, the latter should have a very small mercury bulb so that it records the temperature of the armature as quickly as possible.

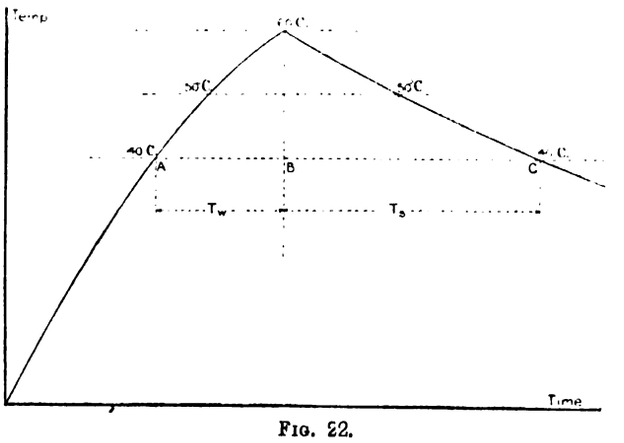

FIG. 22.

It will be found that in these investigations I have preferred approximate methods to exact mathematical ones, the former enabling us to keep in closer touch with the real physical phenomena, and being more easily adaptable to any irregular case; on the other hand, they are precise enough for practical purposes. For investigations on a more mathematical basis, I refer to the excellent article of E. Olschläger "On Intermittent Rating" (*Elektrotechnische Zeitschrift*, p. 1,058, 1900).

## GLASGOW SECTION OF THE INSTITUTION OF ELECTRICAL ENGINEERS.

The monthly meeting of the above section was held at 207, Bath-street, Glasgow, on Tuesday, 11th inst; Prof. Baily being in the chair. The chairman announced that the committee of the section had nominated the following gentlemen as office bearers for next session: Mr. J. M. Munro, chairman; Mr. F. A. Newington, vice-chairman; Mr. E. G. Tidd, secretary and treasurer; and Messrs. Lackie, Goslin, Stothert, Macfee, Sam Mavor, Stewart, Blackwood Murray, Stevenson, and Lowson as members of committee. These nominations are likely to be all confirmed at next meeting. The chairman then called on Mr. W. W. Lackie to reply to the discussion on his paper on "Earthing."

Mr. LACKIE said that if he were to adopt Mr. Munro's suggestion and give a list of the local electric fires, with the names of the contractors whose work was involved, it would certainly lead to an over-heated discussion which he had hardly the temerity to face. If dampness, whether in plaster, stone, or wood, were the only earth, then a further metallic earth connection should be made. He was glad that Mr. Munro agreed with him that each new earth would pass current equal to some pressure divided by its resistance, and that the current which was limited in amount would divide itself inversely as the resistance of each earth. The time taken to make the insulation test at Port Dundas electricity works each week was half an hour. The positive or negative main was earthed through a resistance and the current taken on the middle wire of the feeder before and after the earth was made. Mr. Newington did not see the use of insulating the earth-wire. Mr. Lackie had heard of one or two fires due to the earth-wire being left bare, and it appeared to him a little inconsistent to have a bare wire running for some length across a basement when such a wire would be called upon at certain times to carry considerable current. Insulating the earth-wire had also the advantage that it was readily distinguishable for earth connection from telephone and bell wires. Mr. Newington and other speakers had pointed out that although an installation carried out according to Mr. Lackie's ideas would be all right at first, a plumber or bellhanger's pipes would be pretty sure to be subsequently run in such a way as to bring them into contact with the metallic sheathing of the electrical conductors One of Mr. Lackie's main contentions had been that in the event of such a contingency there was absolutely no means of testing, with the existing wiring practice, the real state of affairs, whereas if the tubing were known to have been originally clear of all other metal work it could be tested after the plumber had finished his work to ascertain whether his pipes were in contact with the cable sheathing or not. All insurance companies insisted on metal sheathing being kept clear of gas-pipes, and there was no electrical difference between sheathing being in contact with a gas-pipe and its being in contact with an iron beam or girder with which a gas-pipe is in contact. Mr. Mavor was wrong in assuming that Mr. Lackie was coming round to the idea that it was not safe to run electrical conductors without an earth protection. Formerly they had laid their lead-sheathed cables in Glasgow in iron troughs; now they were definitely convinced that this was quite a mistake. Trouble had been experienced with arcing and fusion between the lead sheathing and the iron troughs when the lead got alive by accident. Two alternatives presented themselves—viz, either to use metallic-sheathed cables and put them inside a non-metallic box, or to get a non-metallic sheathed cable and put it inside an iron box, in both cases running the box up solid with compound. They had now got a non-metallic sheathed cable which they ran up in wooden boxes with no metallic sheath or earth protection, and it was proving most satisfactory. The current returning by the tramway rail was not the same as that which flows when an earth took place on an electric lighting or power installation. In the case of tramways it was a fixed current, and would divide up in proportion to the conductivity of each path, but the tramway rails need not necessarily be the earth, but are an earth of their own. The London County Council had put down an insulated positive and negative, and he believed other tramway companies and corporations would do the same if they could afford to do so. He did not understand Mr. Mavor's contention that the real trouble arises, not between one of the conductors and the earth, but between two conductors when the flash takes place inside the metal box or other place where a fault occurred. The trouble undoubtedly

Digitized by Google

did occur with one conductor only coming in contact with the metal sheathing, and also the current leaving the metal sheathing and other metal work, and the great difference of potential was practically between the point at which the fault occurred and the earth proper. Mr. Lackie was in agreement with the Board of Trade regulations, and Mr. Mavor said that so far as these regulations were concerned the requirements of the paper were very proper. Mr. Lackie agreed that Simplex tubing of the light gauge ought to be abolished and only proper screwed tubing used. The rules of the American Institute of Electrical Engineers state that the iron tubing used for protecting conductors shall be of a certain gauge corresponding to our gas barrel. The cost of a resistance such as Mr. McWhirter expected the speaker would require to carry 70 amperes with a pressure of 200 volts would be more like £25 or £30 than £500, but where a consumer got into the habit of inserting larger fuses in faulty circuits, no system of earthing would avail for such a consumer's wiring. With regard to break-down in lead-covered wire, such faults did not occur in larger cables. Small stranded wires in being tinned became hard and brassy. The possibility of using the electricity supply for working electric bells had been mentioned. The risk of shock, however, from bell pushes, which were not as a rule very highly insulated, was a drawback. He was of opinion that by keeping what Mr. Maxwell had called their fourth conductor insulated throughout its run the work of the outside testing department would be greatly lessened, for if this one conductor were right the other three would be bound to be right, and there would be 99 per cent. fewer complaints. He did not agree with Mr. Mordey in thinking that the rise of voltage to 200 and 250 had been brought about in the interests of the undertakers rather than for the benefit of the consumers. Mr. Lackie was certain that if the Glasgow Corporation had stuck to the old 100-volt supply, their capital expenditure on mains alone would have been half a million more than it is to-day, and this would in its turn have affected the price of the current to the consumers. In reply to Mr. Mackenzie's contention in favour of a concentric system, Mr. Lackie expressed the opinion that if a concentric system were universally used they would probably have, when a fault occurred, enormous rushes of current that would not only melt soft gas-pipes but iron pipes also. Mr. Lackie maintained that his suggestion would help rather than hinder the electric lighting industry, because while it would not add materially to the cost of installation work, it would help to eliminate fire risk, which, slight though it was, was undoubtedly an impediment.

The CHAIRMAN then called upon Mr. Harold Watson, of the Holland House Electrical Manufacturing Company, Glasgow, to read a paper on "Fittings."

Mr. WATSON'S paper was a short one, and dealt with the subject more from the points of view of the architect and the artist than the electrical engineer. At the outset the author briefly sketched the evolution of electric fittings, starting from the beautiful designs of oil lamp in use among the Greeks, referring to the various developments that took place with the introduction of gas as an illuminant, and then going on to deal more particularly with the changes that took place with the increased use of electrical energy for lighting. The author showed that manufacturers were gradually realising the possibilities of electricity in the design of fittings, and were freeing themselves of the earlier imitation of gas fittings. The present stage of progress might aptly be called that of the renaissance of the hand candle-stick. He was sure that although from use and wont the eye was pleased with a brilliant cluster of lights in the centre of a drawing-room or recreation-room, diffused light from lamps not actually seen, in combination with recessed lights carefully placed, would probably receive more general attention in the future. The lecture was illustrated throughout with sketches, and a model of a counter-weight fitting of the author's own invention was shown. In this fitting a chain arrangement took the place of twin flexible for bearing the strain of the counter-weight and lamp fitting. In describing this model, the author spoke strongly of the dangers and disadvantages of using twin flexible for counter-weight fittings.

A discussion followed. Mr. H. A. MAVOR (Glasgow), the first speaker, said that after the work done by Mr. Benson, the most important development in the design of fittings had been in connection with the work of Mr. McIntosh, a Glasgow man. What Mr. Watson had said about the probable development along the lines of reflected light was very interesting, although the speaker in his personal experience had found great difficulty in keeping the reflecting surface clean. The method adopted by Prof. Barr in his laboratory in the Glasgow University was worthy of mention. It consisted in utilising the cross beams in the ceiling for the diffusion of the light by putting the incandescent lamps in rows on one side of these beams, so that the lamps themselves were not visible to the eye looking in the direction of the front of the room. Mr. Mavor also described the fitting he found most suitable for use in his drawing office. It consisted of a tubular arrangement with a weight at the upper end and an incandescent lamp and shade at the lower end. In the middle of the tube was a ball, which acted as a swivel, and by means of which the lamp could be conveniently placed at any angle.

Mr. J. M. MUNRO (Glasgow), in a lengthy speech, regretted that the technical vocabulary in connection with their industry was so ill chosen. The word "fitting" might mean almost anything. Switches, for instance, were often called fittings. The word "installation" was just as unfortunate. With regard to the paper before them, the author could have added greatly to the interest if he had been less anxious to avoid all appearance of self-advertisement. The speaker thought that all electrical connections ought to be made, if at all possible, by screwed joints in preference to made joints, and he was of opinion also that makers should adopt standard methods of suspension.

Mr. J. D. MACKENZIE (Glasgow) said he did not agree with Mr. Munro with regard to screwed connections for making joints. Screws had a nasty habit of working loose, and there was nothing better than a good soldered joint. The speaker thought the word "electrolier" was as inadequate as some of the other words to which Mr. Munro had referred.

Mr. TIDD (Glasgow) described a method whereby he was easily able to take down his electric fittings. This consisted of an arrangement of hooks upon which the fittings themselves were hung, the wires in the fitting being connected to the conductors by means of bayonet lampholders.

The CHAIRMAN also spoke.

Mr. WATSON, in reply, said that there was still much to be done in illumination by means of reflected light. Designers of fittings were often electricians nowadays, and they understood what was wanted in a fitting from the wiring contractors' point of view. Mr. Watson thought that Mr. Mackenzie was right with regard to screwed joints being less desirable than soldered ones. He was of opinion, however, that fittings should be sent out by the maker wired and ready for erection, and that all jointing should be done in the workshop. He regretted that more had not been said with regard to the use of flexible, because he thought that the use of flexible was a question that required serious consideration.

## FORTHCOMING EVENTS.

THURSDAY, APRIL 27.

**Institution of Electrical Engineers.**—At 8 p.m., discussion of Mr. B J. Arnold's address to the joint meeting at St. Louis "On the Problem of the Alternate-Current Motor applied to Traction," and Mr. F. Creedy's paper "The Alternate-Current Series Motor."

## PERSONAL.

The Carlisle Town Council have increased the salary of the deputy electrical engineer (Mr. Scurfield) from £150 to £175 per annum, and have resolved to make a telephonic connection between his house and the electricity station.

The Southampton Town Council have decided to appoint Mr. Street, the borough electrical engineer, general manager of the tramways department for a period of 12 months, in addition to his present duties

## UNSOLVED PROBLEMS.

The James Forrest lecture which was delivered by Colonel R. E. Crompton, C.B., before the Institution of Civil Engineers last week, forms an excellent *résumé* of the present state of progress in electrical engineering. The lecture, supposed to be devoted to unsolved problems, contained many descriptions of problems which had been actually solved within recent times. The solution of these, however incomplete it may be in certain cases, argued well for the final solving of the other problems which Colonel Crompton brought to the notice of his audience. In fact, in a number of instances he was able to predict with considerable assurance the direction in which we should look for progress towards the final overcoming of the difficult problems involved. These he divided into two groups—*i.e.*, those set for us by Nature herself, and which chiefly concern scientific investigators, and those which present themselves to engineers making use of electrical energy for man's service. The first class of problem still has to be considered by engineers in order to avoid interference with his works. For instance, the explanation of ball lightning has yet to be given. This was pointed out by Colonel Crompton at the beginning of last week, and a new record as to the phenomena in question was obtained on Sunday last at Richmond. In this instance a church was struck, and a number of observers state that they saw what appeared to be a huge ball of fire descending from the clouds. This exploded with a loud report near the church steeple. The explosion of the fire-ball was described by a military officer as resembling the explosion of a shell from a siege gun. This account agrees with others described in the lecture, and yet our scientific investigators are unable to give any reasonable explanation of a discharge of electricity resulting in a ball of fire moving so slowly as to be readily followed by the eye. In this subject, as in the phenomena connected with terrestrial magnetism, much remains to be done before a true explanation of the known phenomena can be given. While electrical engineers have hindered to a certain extent the work in magnetic observatories, they have only done so in the interest of the general public. Thus the introduction of electric tramways with earth returns has resulted in the moving of magnetic observatories into secluded spots where the variations in the earth's field can be watched and recorded without interference. It was when Colonel Crompton turned to the electrical engineering problem of the day that he excited the keenest attention. This is so from the fact that he has personally been responsible for the solution of so many difficulties. Thus in the early days he had to deal with pioneering work in the design of dynamos, in the construction of light and power distribution systems, and the many accessories connected therewith. The lecture, as will be seen from our columns, contains the description of how many of these problems have been solved. For instance, the insulation troubles in the early dynamos seemed almost insuperable, and even now it is no easy matter to ensure that the insulation shall be able to resist both moisture and heat while retaining its mechanical properties. Still, this problem has practically been solved for machines of ordinary size and speed. The introduction of the steam-turbine as the prime mover for large generating units exaggerates the mechanical difficulties of insulation owing to the enormous centrifugal forces involved. This problem is now being considered by most of our large manufacturers, and the experience obtained from the various machines running at high speeds will soon determine what general lines are likely to lead to success. The detailed improvements in storage batteries, although

Digitized by Google

many, still leave a great deal to be done before the storage of electricity is sufficiently cheap and simple as to render the power factor of the load of as little importance to the electrical engineer as it is to the gas undertaking. The great problem, however, which is before us at the present time is the electrification of our railways. As to this, Colonel Crompton, speaking before an institution whose members have been responsible for the great railway systems of the country, was comparatively modest in his claims. He was sure that electric traction could supersede the present steam haulage on our railways at the schedule speeds which are now in use. He was not so certain as to the raising of these schedule speeds to a considerable extent by electric haulage, as he thought that the locomotive designers would meet the competition by improvements which would enable steam locomotives to run also at higher schedules and safely. The problem is one on which experience is being accumulated at a rapid rate, and with the introduction of the single-phase motor a great step has been made towards the economic electrification of main lines. Many other problems are given in the lecture as awaiting solution, and the young electrical engineer cannot do better than read the 1905 James Forrest lecture when looking for an outlet for his energy.

## SINGLE-PHASE RAILWAY MOTORS.

Dr. Behn-Eschenburg in an article in the *Schweizerische Elektrotechnische Zeitschrift* deals with recent work of the Maschinenfabrik Oerlikon in connection with single-phase motors, and gives some interesting test results. Curves are given of a 35-h.p. (continuous rating) motor used (1) as a direct-current motor at 200 volts; (2) as a plain series alternating motor at 200 volts and 22 ⁓; (3) as a repulsion motor at 230 volts, 44 ⁓; and (4) as a compensated series motor, with additional short-circuited brushes (Latour's method) at 250 volts, 44 ⁓.

The motor is a six-polar one, but has no salient poles, the windings on both rotor and stator being similar to a direct-current armature winding, and the rotor winding being connected to an ordinary commutator without the interposition of any high-resistance connections. The stator winding is divided into two similar parts with their magnetic axes half a pole-pitch apart. One of these parts is the exciting winding proper and the other is the compensating winding to counteract the field set up by the armature current. For cases (3) and (4) the two parts of the stator winding were combined into a single regular winding. The slots on both stator and rotor are half closed. For cases (1), (2), and (3) six sets of brushes were used and for (4) 12 sets. Each brush was 8mm. wide, and in cases (1) and (2) the brushes were set on the neutral line. The air-gap of the motor is 1mm. a side.

The temperature rise in all four cases was found to be about the same, and in no case exceeded 45deg. C. after four hours at full load. The sparklessness and the state of the commutator at the end of each run were also found to be equally satisfactory in all four cases. Even at speeds above 1,000 revolutions, or below 500 revolutions, the machine was sparkless in cases (1) and (2), but in cases (3) and (4) special devices for counteracting the voltage induced in the short-circuited section would be required at these speeds. In case (2) this short-circuit voltage can easily be kept within the required limit, even with large overloads, by proportioning the iron sections so that they become saturated before the maximum safe field strength is exceeded. In cases (3) and (4), however, the higher periodicity, necessitated by power-factor considerations, involves a higher induced short-circuit voltage at starting and at speeds much below or much above synchronism, though at, or about, synchronism this voltage practically disappears. The tests show that the short-circuit induced voltage per section at starting was 2·6 volts with 200 amperes 22 ⁓ in case (2), and 4·5 volts at 130 amperes 44 ⁓ in cases (3) and (4). In the case of the repulsion motor (3) the brushes were short-circuited together and set at an angle of 18 (electrical) degrees, or one-tenth of a pole-pitch from the magnetic axis, as this position was found to give about the correct current in the rotor, as indicated by armature and commutator heating at 35 h.p., 1,000 revolutions, and by the power factor approaching its maximum value.

The following table shows the behaviour of the motor under the different conditions as read off the curves accompanying the article:

| Motor tested as | H.P. | Revs. | Volts. | Amps. | ⁓ | Efficiency | Cos $\phi$. |
|---|---|---|---|---|---|---|---|
| 1. Direct-current series motor.. | 35 | 1,000 | 187 | 160 | — | 85 % | — |
| 2. Series alternating motor ... | 35 | 1,000 | 182 | 182 | 22 | 81·5 % | 95 % |
| 3. Repulsion motor | 35 | 880 | 225 | 156 | 44 | 83 % | 90 % |
| 4. Latour motor.. | 35 | 880 | 255 | 128 | 44 | 81 % | 100 % |

The weight of the motor complete without gear is 1,000 kg.

The article concludes with a short description, together with photographs and some test results, of a 200-h.p. single-phase geared railway motor. This is a plain series motor, with eight salient poles, working at 260 volts, 600 amperes, 15 ⁓, at 650 revolutions normal and 1,000 revolutions maximum. The ampere-turns per unit of armature periphery and the number of commutator segments were kept as high as possible, the width of the latter at the surface being 4·8 mm. The armature diameter is 750mm., length of armature core parallel to the shaft 290mm., diameter of commutator 580mm, and over-all diameter of outer frame 1,245mm. A special device for reducing the sparking voltage is employed, but is not described. No special compensating winding for reducing the armature distortion is employed, but the design is such as to reduce this to a minimum. Commutation was found to be equally good over the whole range of speed from 0 to 1,100 revolutions. The induced voltage per section is only two volts when the torque is 200 kilogram-metres, and only increases some 12 per cent. when the torque increases to 350 kilogram-metres, owing to the dimensioning of the iron circuits. The curves given show that at 200 h.p. the input is 263 volts, 600 amperes, 680 revolutions, the efficiency being 92 per cent., and the power factor 95 per cent. The weight of the motor complete with three bearings is 3,000 kg.

## UNSOLVED PROBLEMS IN ELECTRICAL ENGINEERING.*

BY COLONEL R. E. B. CROMPTON, C.B., M.I.C.E.

*(Continued from page 527.)*

From the first we found that the most convenient method of forming our existing coil or helix was by winding up into a coil on the core itself, or on a separate frame slipped on to it, copper wire of circular cross-section, and covered with a fibrous insulating material such as cotton or silk thread. This method of coil winding has held up to the present date, chiefly on account of its convenience and of the very perfect and economical methods of covering the wire with silk and cotton thread, or in some cases with spiral paper strip, which have been from time to time introduced, but in all these cases the mass of the wound coil is largely made up of insulating material, as, on account of the circular section of the copper itself, there is much wasted space. Moreover, on account of the low heat conductivity of the mass of insulation and the waste spaces entrapping air, the heat-conducting properties of the coil as a whole is very low. The recent series of experiments that have been carried out for the Standards Committee by the National Physical Laboratory have shown very clearly that with coils of this class the temperature at the hottest part of the coil is frequently 35deg. F. in excess of its mean temperature, and as in this case the maximum temperature of the coil is the

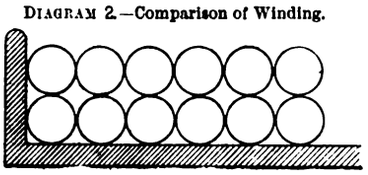
* The "James Forrest" lecture, 1905, delivered before the Institution of Civil Engineers.

Digitized by Google

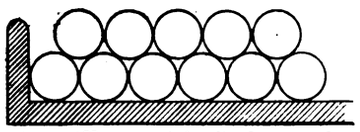
governing factor, it is evident that if we can so increase the heat conductivity so as to materially reduce this difference between the maximum and mean temperatures, so can we improve the coil both in the cost of its production and in its economical working.

I have prepared diagram 2 showing winding in three forms, the first showing the relation of copper to insulation and wasted space when cylindrical cotton or paper covered wires are wound on to short formers provided with flanges of the full depth of the winding; the second, which is also a usual form and allows of a more solidly wound coil—*i.e.*, when the ends of the winding are stepped back—the alternate layers fitting in to some extent between the depressions of the first layer. But for the third case I have shown an ideal winding of a coil to produce the same results as to the required magnetic field and to give sufficient cooling surface to get rid of the heat, but using less copper and having greater heat conductivity due to the continuity of the copper from the inside to the outside of the coil. This ideal winding you will see consists of thin copper strip wound on its edge into correct position by suitable machinery, each turn being insulated from the adjacent turn by a thin film of insulating material applied to it at the time it is being wound. This ideal form of coil winding has already been occasionally used in practice for the larger coils required for certain transformers and for the magnets of large generators and

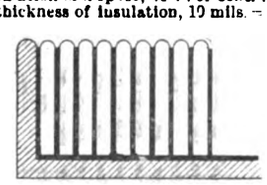
DIAGRAM 2.—Comparison of Winding.



Case I.—Ampere turns, 120; current density, 1; area of copper, 54·5 per cent.; area of insulation and space, 45·5 per cent.; diameter of wire, 100 mils. = 1in.; thickness of insulation, 10 mils. = ·01in.



Case II.—Ampere turns, 120; current density, 1; area of copper, 58·6 per cent.; area of insulation and space, 41·4 per cent.; diameter of wire, 100 mils. = 1in.; thickness of insulation, 10 mils. = ·01in.



Case III.—Ampere turns, 121; current density, 1·15; area of copper, 68·9 per cent.; area of insulation and space, 31·1 per cent.; total space occupied, 59·34 per cent.; thickness of insulation, 10 mils. ·01in.

motors, and it will be seen that we gain greatly in reducing bulk of the winding, weight, and cost of copper, and as the magnet arms are shorter we gain greatly in the size and cost of the framework of the machine, but in order to apply it generally to the smaller class of apparatus we still require a combination of rolling, winding, and insulating machinery which will take the rough copper strip and at one operation reduce it to the correct cross-section, winding it into place, and apply the coating of insulating material. In my diagram I have not taken advantage of the reduced thickness of insulating material although I might have done so, but even as shown the reduction in size, weight, and cost are very noteworthy. And it is the constructional problem which I here set and formulate for your consideration.

We now come to insulating problems. As I have already said, up to the present we have been content with the older method of fibrous insulation, sometimes untreated, but in other cases impregnated with an insulating varnish or enamel. In order to render our coils non-hygroscopic, so that we can maintain sufficient insulation in moist atmosphere, we have already introduced vacuum machinery to remove the moisture after they are wound, and afterwards we inject our waterproofing and insulating varnishes under pressure to fill up as far as possible the interstices, at all events in the outer layers of winding, at the same time we slightly increase the heat-conducting qualities of the coil as a mass. But, unfortunately, it is difficult by such impregnation to make the coils waterproof to a satisfactory extent, for the fact that when these coils are at work they are alternately heated and cooled of itself tends to aid the re-entrance of moisture, at all events in this climate.

Quite recently in connection with this winding question another difficulty has been observed by Highfield and others—*i.e.*, the formation of ozone, and, finally, of nitric acid inside the coils, which has in many cases destroyed the fibrous material used for insulation. All this points to the desirability of dispensing with fibrous material and of replacing it by an insulating material which will have sufficient dielectric strength, will stand the action of nitric acid, and facilitate heat conductivity. A good deal has been recently done in this direction, and notable advances have been made towards increasing the temperature up to which such insulating compounds can be worked without notable decrease of their dielectric strength, so that although a few years ago we considered a temperature of 100deg. C. or 212deg. F. as quite the outside temperature at which coils could be satisfactorily worked for lengthened periods, we are now slowly coming to the opinion that it is desirable that we should work them at far higher temperatures, and that it is quite reasonable to hope that our chemists will furnish us with suitable insulating materials for impregnation, or coating our conductors, and which will stand continuously temperatures up to at least 200deg. C. or 390deg F. If we are successful in obtaining the two requirements which I have mentioned—*i.e.*, the reduction in the sizes of our coils, as shown in the third case of my diagram, and in obtaining the higher temperatures at which we can work them without endangering the durability of our plant—we shall benefit greatly, both contractors and users, by reducing the bulk, weight, and cost of our machinery without in any way impairing its efficiency.

The recent introduction of high-speed turbo-generators has called attention to the difficulties of designing both the cores and the winding of the revolving fields so that they can successfully withstand the severe mechanical stresses to which they are exposed at these extreme speeds. Much ingenuity has already been exercised in attempting to reconcile the antagonistic requirements of great mechanical strength to resist centrifugal forces combined with minute sub-division of the score to prevent a free path for the eddy currents. It will be seen that here the difficulties of the designer are very great, and the problem of overcoming them is yet in its early stages.

Although we are all agreed that the development of electrical storage is desirable from every point of view, we engineers are still divided into two camps—those who believe in storage in its present stage of development, and those who hold the contrary opinion, that until we have at command a form of electrical storage differing widely from that furnished by the lead-couple accumulator of Planté, we had better leave storage severely alone, and trust to careful design and the parallelising of our generating apparatus or to similar precautions to obtain sufficient regularity of supply to our users.

I have from the first held strongly to the former view, as I have all along considered that in the lead-couple accumulator we have a most valuable means of obtaining sufficient storage for our purposes, and that we had far better address our energies to encouraging the development and improved manufacture of the storage that we have, rather than to sit with our hands before us awaiting the invention of something which, after all, we may never obtain.

It may surprise many of you to hear how great have been the improvements in the lead-couple accumulator during the 15 years or so that it has been in practical use. These developments have been steady, continuous, and have been very lately discussed; but the fact remains that the accumulator, as we now have it, has taken rank as a part of our electrical plant which is well understood, and from the use of which many of us are obtaining great economical benefit.

The causes of this improvement are two-fold. Our early troubles arose partly from difficulties in the manufacture of

Digitized by Google

the plates in the accumulator cells; means were adopted to hasten the formation of these plates during their manufacture, for which we paid somewhat dearly by their shortened life. Another and very important cause of our early troubles was that for a long time we continued to use the cells themselves as a means of regulating our electrical pressures. This introduced conditions extremely unfavourable to the regulating cells of our batteries of accumulators, but since, owing to the discoveries of Chamen, Highfield, and others, we have obtained regulation by means of automatic motor-generators, to which the name of boosters has been generally given. This difficulty has been largely removed, so that the life of a battery is no longer confined to the short life of its regulating cells, but is that of the life of the whole mass of cells that are all working under equal conditions.

The heavy cost of upkeep of the early accumulators was due to the fact that the active material on which storage capacity depends, became detached from the plates and fell to the bottom of the cells in the form of an inert mud, which required to be removed at frequent intervals of time, and was a great source of loss and annoyance.

The value of recent improvements may be gauged by the fact that the formation of deposit in the bottom of the cells from this detached active material has been reduced to one-quarter of its quantity during the last five years, and we may safely say that the durability and cost of upkeep of these accumulators has been reduced in the same proportion.

These improvements have been noticed by those who have closely studied this question, and has been followed by a great increase in the use of storage, especially where the demand on the electrical energy has been intermittent, or has been confined to short hours, such as in towns or villages, where the demand up to the present has been principally for domestic purposes during hours when artificial light is required; so that at present my view is that we can design far the most economical plant for supplying electrical energy for these cases by combining the most economical generating plant that we know of, which is the combination of the internal-combustion engine with a suction gas plant worked for long hours, and thereby charging storage sufficient to deal with the bulk of the load, but supplying the short hours of peak load from steam plant specially designed to work for short hours at a maximum efficiency.

The storage problem which has been insufficiently developed, but to which much attention is now being directed, is that of portable storage. We require a box of power, as it was first termed by Lord Kelvin when the Faure accumulator was brought over to this country. I must remind you that Lord Kelvin was not alone in thinking that we had already within our reach the power of storing considerable amounts of power in boxes of reasonable size and weight, which could be transported from the point at which they were charged to the point at which the power was to be utilised. After long years of disappointing delay we do see this realised in the very considerable number of private carriages driven by electrical means which we now see in the streets of London and Paris.

Here, again, we have been told that the lead-couple accumulator is hopeless, and that we must wait for something lighter and stronger, such as Edison has been working on for some years past, but again practice has shown that we are far from obtaining anything to take the place of the lead couple, and if we are to argue from the progress that I have already indicated as already having taken place in the fixed batteries we use in connection with our distribution systems, it is reasonable to suppose that similar progress will be made in the portable accumulators, and that a few years hence we shall see great developments. It is probable that these developments will rather take the form of a better organisation of methods of using, of obtaining facilities for recharging and repairing the accumulators we already have, but this is more the province of the commercial organiser than of the engineer himself.

It is quite certain that an enormous impulse would be given to the production of electrically-driven vehicles when the boxes of accumulators and the means of charging them are sufficiently standardised. I am glad to say that the matter has been already taken up by the Standards Committee which is supported by this institution, and in this respect the outlook is distinctly hopeful.

The railway problem, which is of the highest interest and importance to my audience, would occupy not one but a series of lectures. I must confine my remarks to pointing out that one solution of the problem seems already within our reach—namely, that of the utilisation of single-phase alternating currents for long-distance transmission which only requires two insulated wires and two contacts. The engineering and mechanical secondary problems still unsolved are easy ones. We have the choice between the type of series motors as made by Finzi in Italy, and that of the Winter and Eichberg compensated repulsion motors made by the Allgemeine Company. The difference between these two types lies principally in the size of the transforming apparatus which must be carried on the train. In the first instance this must be equal in capacity to the total output of the motor equipment, whereas with the repulsion motor the transformer need only have a capacity of one-tenth the rated capacity of the motors. Our future choice lies between these two or similar systems or modifications of them.

As regards the problem of the third rail, its difficulty and dangers, and of substituting the overhead work necessary for these single-phase motors, it is a mere draughtsman's question, and is quite certain to be satisfactorily dealt with. I think we can even now answer two questions. The first is: Can electric traction supersede the present steam haulage at the schedule speeds which are at present in use on our railways? To this question we electrical men say that, although there are many secondary problems arising out of it, they are all easily solvable, and we have no doubt whatever that we can answer the question in the affirmative. The second railway question is: Can we, by the introduction of electric haulage, raise to a notable degree the present schedule speeds, and from this cause alone become very formidable competitors to long-distance steam haulage? Although there are many electrical engineers who would answer this question in the affirmative with as much confidence as they answer the first one, yet, personally, I am not quite so sure. I see that, spurred by our electrical competition, the designers of the steam locomotive are likely to make further efforts, and I feel sure that if we electrical men can work to schedule speeds of 100 miles an hour, the steam locomotive also can be improved so as to work at the same speed with equal safety.

As to long-distance goods traffic, I do not think we are likely to attack this problem for years to come. None of the engineers who I have met, either in England or America, seem to think that electricity is ever likely to replace steam for this work—of course I mean in our present knowledge of the generation and supply of electrical energy.

Our railway problems would be greatly assisted by the solution of another mechanical problem closely connected with it, or with the driving of any machinery, such as rolling-mills, where the starting torque is very great and very variable, whereas the source of energy for driving is constant. You are all familiar with the attempts to deal with this matter mechanically on the motorcar or motor-omnibus by the change speed gear, but I believe and hope that the real solution is an electrical one. Ward Leonard has worked it out by the introduction of a motor-dynamo having a variable field, but up to the present all the devices have been heavy and costly; still the problem of producing by electrical means a change of speed and torque gear will be of the utmost value in aiding the work of the mechanical engineer, whether in railway works, rolling-mills, cranes, hoists, or in the propelling mechanism of the steam, petrol, or electrical vehicles which are now beginning to be used so largely on our roads.

Probably the branch of electrical engineering which has already made its greatest advances has been that of perfecting our measuring instruments. This is a matter on which I could dwell with loving interest, but time prevents me from dwelling on it at any length. The instruments that we have already at command for measuring direct currents are already so accurate, and so low priced, that they are commencing to be used for many purposes

Digitized by Google

quite outside the field of electrical engineering proper. By combining them either with a thermal couple, such as copper constantan, iron constantan, or with a platinum rodium or similar alloys, they become the most accurate and convenient methods of measuring temperature from the minute changes necessary in measuring lunar radiation up to extremely high temperatures close to the melting point of platinum. The standard methods of checking these coil instruments by means of the potentiometer are already very perfect, but when we come to the measuring of alternating energy, although the instruments for measuring separately the current and pressures are satisfactory, yet no completely satisfactory method at all approaching the accuracy and simplicity of the direct-current methods for measuring power are as yet available in this case. This is due to the difficulty of measuring current and pressure simultaneously and under such conditions that no corrections have to be made for the difference in phase between the two, wherein lies the all-important power factor. Probably the solution of this problem lies in the further perfecting and simplification of electrostatic means of measuring alternating pressures. Much is to be hoped for from the further development of the beautiful spherical electrostatic instruments devised by Price.

The problems of the further utilisation of electrical energy for the purposes of our daily life are of extreme interest. The first strong impetus given to the discovery of improved means of generating electricity arose from the desire for electric light. First came the arc light, followed by the incandescent lamp, and both have been perfected up to a certain point. By the invention of the enclosed arc we have greatly reduced the cost of labour of recarboning our lamps, and have so far increased their utility by perfecting smaller details of manufacture, and the carbon filaments of our smaller lamps have also reached better efficiency and regularity of light-giving power than was at first the case. Still, as at present produced, they fall short of what is desired in point of efficiency; but there is, nevertheless, room for hope and material benefit in this respect. For years past many minds have been attempting to solve the problem of obtaining increased light from an incandescent filament or wire. The successive appearance of the Nernst, the Auer, von Welsbach, the osmium, and, finally, the tantalum lamp indicate the more or less successful efforts that have been made and which seem likely to yield satisfactory results.

The development of this tantalum lamp has been a striking instance of the way a problem of this kind ought to be attacked. The search for a suitable wire was set about in a thoroughly systematic manner. Tantalum was tried, as it was one of a group of metals that from their known atomic values would be likely to give the desired results. It was then hardly known in its metallic form, so that during the search it was necessary to devise means for obtaining it in sufficient quantity, to draw and toughen the wire, and to mount it in a suitable manner. The result has been a lamp which, although not perfect, does yield many of the results that were expected from it, and the enquiry will very probably lead to notable additions to our knowledge of this part of the lighting problem.

Quite recently we have witnessed the introduction of lamps yielding strange coloured lights, on the one hand the blue of the Cooper Hewitt mercury vapour lamp, and at the other end of the scale the orange-flame carbon arc lamp. An investigation into this question of the colours which are best suited to obtain clear visual definition by artificial light is sorely needed. Such an investigation was begun 10 years ago by Langley in America, Blondel in France, and by Barr and Phillips in this country, but of late years little further has been heard on this extremely important subject. The revival or reintroduction of these modern lamps show that the problem is an important one. More than 12 years ago Langley defined the brightness of light as the intensity of retinal absorption, and probably this is what most of us believe it to be. He pointed out that the effect of lights of different colour on the retina varied with the individuals and with the age of individuals, so that the greatest visual intensity is obtained with younger men when the light is rich in yellow rays, with the older men when the light is richer in the green and violet. Now that we have at command electric lamps that can give us colours of both kinds, it will be interesting to notice how far Langley's ideas are corroborated now that we have such full opportunities for investigating them on a larger scale. We are told that the Cooper Hewitt lamp gives excellent definition and does not fatigue the eye when exposed to the trying work of reading fine scales, or wherever high definition is of first importance, and has to be obtained by the aid of artificial light.

*(To be concluded.)*

## TRADE NOTICES AND NOVELTIES.

### The Lahmeyer High-Tension Oil Fuse.

The essential features of the high-tension oil fuses of the Lahmeyer Electrical Company, of 109-111, New Oxford-street, W.C., are apparent from the illustrations herewith. The fuses

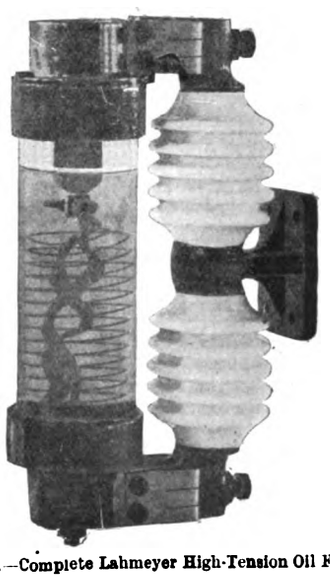


FIG. 1.—Complete Lahmeyer High-Tension Oil Fuse.

are standardised for 12,000 volts and up to 120 amperes in capacity. The complete fuse is shown in Fig. 1. The fuse wire is not immersed in oil, but is contained in the metallic fusing chamber (Fig. 2). This is lined with insulation, and the lower part just enters the oil. The lower end of the fuse is connected by a flexible copper connection to the lower contact of the fuse carrier. This fuse chamber may be compared

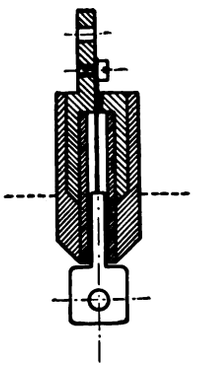

FIG. 2.—Fusing Chamber with Fuse Wire.

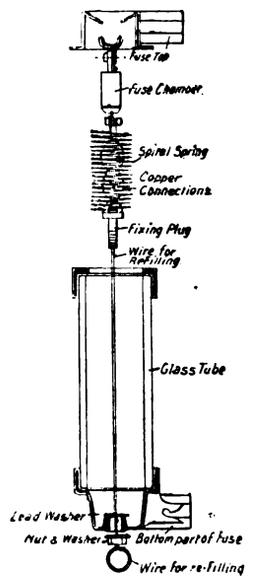

FIG. 3.—Details of Fuse, showing method of replacing.

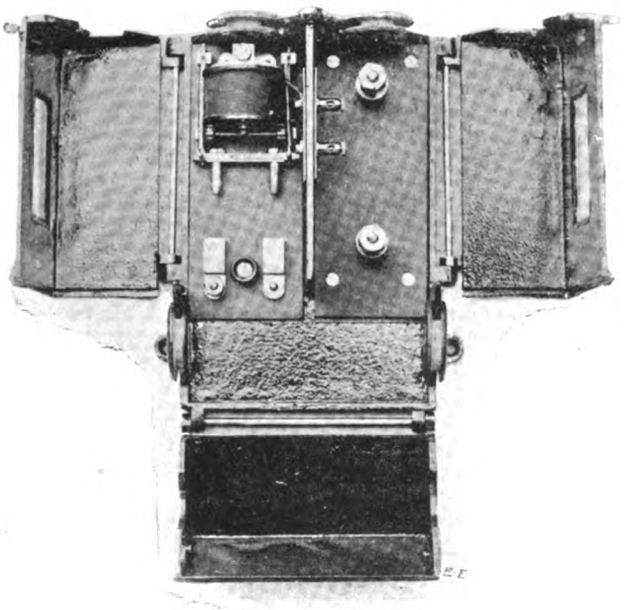
to a gun with its muzzle placed under oil. The fuse, when it blows, causes a rapid increase of the gaseous pressure inside this chamber, which discharges downwards into the oil. This forces the lower terminal of the fuse into the oil, and also the heated gases are promptly cooled by passing into the same. The interruption of the circuit is thus instantaneous, and it does not

Digitized by Google

depend on the mechanical action of the spring, which is solely used to keep the fuse wire in tension. The fact that the fuse wire is clear of the oil makes the fusing current a definite quantity. Fig. 3 shows the details of the fuse carrier and the method of replacing the fuse wire.

### Earthing Device for Metallic Conduits.

Mr. A. J. Beaumont, of 78, Bishopsthorpe-road, York, sends us particulars of apparatus he has devised for cutting off the supply to any installation should there be any leakage to earth through either the metallic covering of the conductors or the frames of motors, etc. This we illustrate herewith. It consists of an automatic main switch, which is held in its closed position by a catch. The switch is pulled open by the springs seen at either side of the coil as soon as the catch is tripped by a small current passing round the solenoid. The metallic tubing in the installation on the lead sheathing of the cable is connected to form a continuous circuit, and then earthed through the solenoid in question. If, then, any current passes



The Beaumont Automatic Main Switch in off position.

from any conductor to the tubing, the solenoid trips the main switch and cuts off the supply of current. It will be seen that this makes it necessary for the metallic tubes to be kept from contact with any earthed conductors in the walls, such as water-pipes or girders. Mr. Beaumont tells us that he frequently finds the resistance to earth of such a system of conduits to be over 2,000 ohms. In large buildings it is advisable to have a separate earthing device between the feeding tubes and the distributing tubes, and to have a larger one on the mains to protect the feeding tubes. This larger cut-out would require one or two amperes to cause it to act, while the distributing boards would be protected by the ¼-ampere cut-outs. The cut-outs can, of course, be arranged to act with any desired currents to earth. The apparatus can also be actuated by a heat coil instead of by a solenoid. The efficacy of the device as a protection against fire depends on the continuity of the metallic tubing or cable sheath.

### Catalogues Received.

N.S. Accumulators.—The new catalogue of the N.S. Electric Storage Company contains particulars of further developments in the manufacture of lead storage cells by the firm in question. There is a great field for storage batteries to be used on motor-cars for ignition purposes. For this purpose and also for train lighting the portable accumulators manufactured by the Horton Kirby firm have exceptional advantages. The construction of the cell is in such a form that it is physically impossible for the active material to become detached from the plates. In this N.S. cell the electrodes are made up of alternate layers of pellets composed respectively of oxide of lead and sponge lead. They are divided the one from the other by a porous diaphragm, and are packed in so that a permanent connection is obtained between the pellets and the conductors. In the list before us these cells are described in a range of sizes varying in capacity from 20 ampere-hours up to 80 for motorcar ignition work. For train-lighting purposes two sizes are made—respectively 230 and 350 per ampere hour capacity. The firm also manufacture large cells for use in central-station work.

Electrical Measuring Instruments.—Messrs. Isenthal and Co. have given great attention to the manufacture of laboratory measuring instruments and rheostats for use in technical colleges. Their 1905 list of these includes also a number of commercial instruments. Thus their pocket voltmeters are extremely useful to all motorists. Ammeters of the same type are now being supplied, which afford a ready means of testing the output of small accumulators for ignition purposes. The firm standardise a series of electromagnetic instruments for workshop purposes, and their megohmeter is a useful adjunct to the switchboard of an isolated installation. Voltmeters and ammeters of the moving-coil type are included in the list. The latter portion of the catalogue deals with instruments for the laboratory.

J. H. Holmes and Co. send us their list of installations in textile mills. We gather from the information on this that the bulk of the installations are for lighting, but in certain cases motors of a considerable aggregate horse-power have been installed. From the list of mills given there is obviously a great field for the further extension of electric driving.

The Cleveland Crane and Car Company have sent us a series of their bulletins dealing with various types of their electric cranes and hoists. The bulletin distinguished by the letter F describes an interesting electric runway manufactured by the firm. The electric motor, complete with hoisting gear, is arranged to run on the lower flanges of a continuous girder. The current is led to the motor by means of two insulated wires on the one side of the girder. Vertical spring trolleys are used to collect the current from these wires, while the motor is controlled by means of ropes from the floor level. The system affords convenient means of transporting heavy pieces of material in factories where the headroom is limited. The other types of cranes manufactured by the firm are exceedingly interesting in construction, and we notice that the three-motor type is very largely used. The full address of the firm is Wickliffe, Ohio.

Single-Phase Motors.—The Lahmeyer Electrical Company standardise a line of single-phase motors for working on 50-period circuits for output from ⅛ h.p. up to 20 h.p. The voltages for the smaller sizes up to 1¼ h.p. are 110 and 220, for larger outputs motors for 500 volts are also stocked. The motors can either be of the wire-wound slip-ring type or with squirrel-cage motors. The list forwarded to us illustrates the general design of the motors, and gives useful information as to detailed prices of the motors and their accessories.

## NOTES ON SOFTENING AND PURIFICATION OF WATER FOR STEAM RAISING.*

BY LOUIS J. LE CLAIR, ASSOC. GLASGOW TECH. COLL., A.M.I E.E.

Although methods of treating hard waters were known many years before Dr. Clark patented his process in 1841, until comparatively recent years little attention had been directed to the treatment of boiler feed water, in "softeners" for the prevention of scale formation, or in "purifiers" for the elimination of grease from condensation water.

Both scale-forming constituents and grease are most objectionable in feed water, and every effort should be made to reduce the former to a minimum and entirely eliminate the latter. Scale reduces the heat-transmitting efficiency of boiler plates, as may be seen by the curve in Fig. 1. The average loss

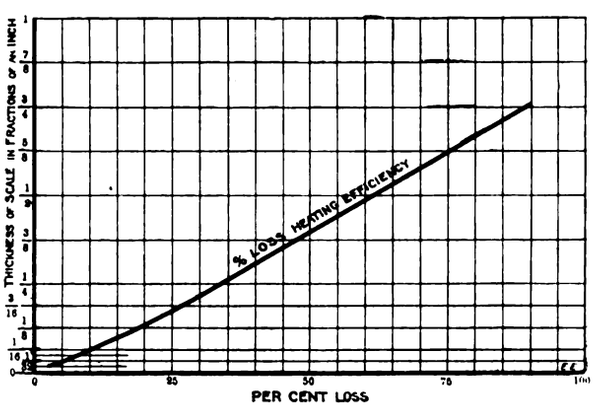


Fig. 1. Loss of Heating Efficiency due to Scale on Boiler Plates.

amounts to about 8 per cent. for each 1/16in. thickness of scale. Certain scales, however, resist the transmission more than others, sometimes nearly doubling the above figure. It is also worth remembering, with regard to water-tube boilers, that the formation of scale decreases the internal diameter, and, in consequence, the heating surface of the tubes. In boiler furnaces free from scale and soot the "thermal head" between the surface of the metal next to the fire and that next to the water

* Paper read before the Dublin Local Section of Institution of Electrical Engineers, April 13, 1905.

Digitized by Google

is comparatively small. A coating of scale or grease increases this considerably, as may be seen from Fig. 2, which is a diagram of some of Hirsch's experiments, carried out with a clean plate and pure water, and then with coatings of oil and scale. It will be observed that at 45lb. per square foot per hour (for a flame temperature of about 1,500deg. F.), a comparison between temperatures on the fire-side when using a clean plate, then one with a layer of scale 1/5in. thick, shows the former to be about 380deg. F. and the latter 665deg. F.—an increase of 285deg. F. It might be mentioned that iron at 750deg. F. is just visible in the dark as a dull red. Table I., which is made up of extracts from Sir A. Durston's experiments on the effect of grease in boilers, again shows the great retardation of heat transmission and the heating up of boiler plates from this cause (*Proc.* Inst. Naval Architects, 1893).

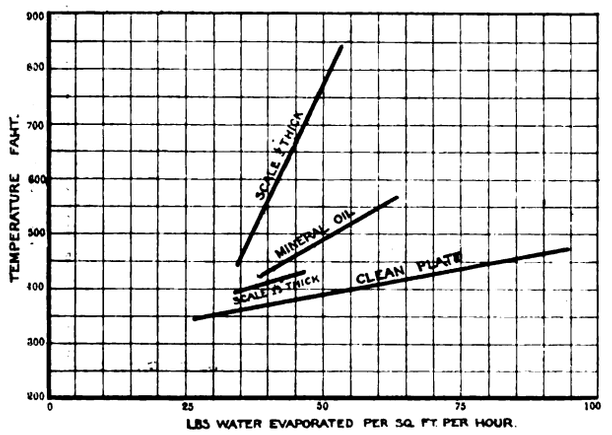

FIG. 2.—Temperature on Fire Side of Boiler Plate ¾in. thick when Evaporating Pure Water at 212deg. F. Water Side of Plates clean and coated with Scale and Oil. (Hirsch.)

TABLE I.—Showing Temperatures of Plates with Clean and Greasy Surfaces (Durston).

| Experiment. | Thickness of plate. | Thickness of grease. | Temperature of fire. | Temperature fire-side of plate | Temperature of water. | Difference. |
|---|---|---|---|---|---|---|
| | In. | In. | F°. | F°. | F°. | F°. |
| A | ¼ | — | 1,500 | 240 | 212 | 28·0 |
| B | ¼ | — | 2,200 | 280 | 212 | 68·0 |
| C | ¾ | — | over forge, full blast | 430 | 344·5 | 85·5 |
| D | ¼ | 1/32 | 1,500 | 330 | 212 | 118·0 |
| E | ¾ | 1/16 | over forge, full blast | 510 | 359 | 151·0 |
| F | ¼ | 1/16 | 2,500 | above 550 | 212 | above 338·0 |
| G | ¾ | 1/16 spread up sides | over forge full blast | 617* | 80 | 537·0 |

REMARKS.—Experiments A, B, D, and F were made with open vessel and water boiling at atmospheric pressure. C, E, and G were made in a closed vessel and under pressures corresponding to temperatures given. * This temperature was reached three minutes after placing vessel on fire.

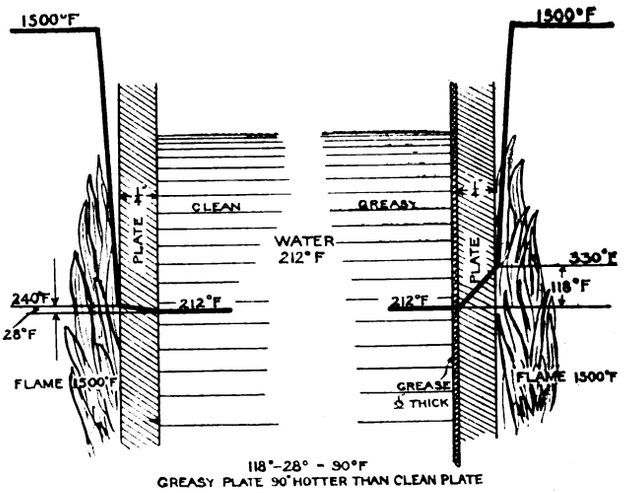
Figs. 3 and 4 show graphically the fall of temperature from the flame to the fire-side of the plate and thence to the water-side for two of the experiments in Table I. The fall from one side to the other or thermal head being with a clean plate 28deg. F., a coating of grease 1/32in. thick increases this to 118deg. F.—*i.e.*, 90deg. F. more than when using a clean plate. These two experiments were carried out with water boiling at atmospheric pressure. Had the pressure been, say, 200lb. per square inch (steam temperature 388deg. F.), and assuming the thermal heads to remain as before, then the temperature at the fire-side would have been 416deg. F. with the clean plate and 506deg. F. with the greasy plate. All these experiments show how rapidly the temperature of boiler plates increases as scale or oil is deposited on their surface. Eventually when the deposit is sufficiently thick collapse ensues, with possible loss of life. Even if the plate temperatures are barely high enough to bring about such serious results, they are quite sufficient to set up enormous varying strains each time the fire-door is opened, ultimately causing grooving and other defects to appear.

The "remedy" generally applied is to have the scale chipped off, entailing considerable expense and putting the boiler out of work for a time. "Prevention" is preferable, and can be accomplished by "softening" and "purification" in proper treatment apparatus before the feed water enters the boiler. The boiler should not be used for any other purpose than raising steam. All patent compositions for treatment of the water inside the boiler should be carefully avoided. If used, they form soluble matter and precipitates inside the boiler, and they are too often added to the water with utter disregard to the proportions necessary for proper precipitation. These compositions generally contain some of the reagents used in water-softening apparatus, and often, in addition, substances injurious to boilers. I have heard of an analysis of one such preparation showing the presence of metallic mercury.

TABLE II.—Principal "Scale-Forming" and "Non-Scale-Forming" Substances

| Scale-forming. | | Non-scale-forming. | |
|---|---|---|---|
| Substance. | Symbol. | Substance. | Symbol. |
| Calcium carbonate..... | $CaCO_3$ | Calcium nitrate..... | $Ca(NO_3)_2$ |
| Calcium sulphate ..... | $CaSO_4$ | Magnesium sulphate.. | $MgSO_4$ |
| Magnesium carbonate. | $MgCO_3$ | Magnesium nitrate ... | $Mg(NO_3)_2$ |
| Magnesium hydrate ... | $Mg(OH)_2$ | Magnesium chloride... | $MgCl_2$ |
| | | Sodium chloride ..... | $NaCl$ |
| | | Sodium sulphate ..... | $Na_2SO_4$ |
| | | Sodium nitrate ..... | $NaNO_3$ |

*Softening.*—Water is a powerful solvent, and whether taken for domestic or technical purposes from reservoirs, wells, rivers, lakes, etc., it has invariably before being collected come in contact with some part of the earth's surface, and in so doing dissolved or carried away certain substances, the amount of which may vary from practically nil to considerable quantities Rain-water, if collected in the country, may be nearly pure, whilst in some districts mineral waters are found, the salts in which are present to such an extent as to impart to them a distinct taste or smell. The salts found in waters and which chiefly concern engineers are given in Table II. These have been divided into scale-forming and non-scale-forming. Calcium and magnesium, in combination with other elements, are freely distributed in nature. The carbonates and sulphates of calcium and magnesium are the chief cause of "hardness" in water.



FIGS. 3 AND 4.—Diagram showing Fall of Temperature from Flame to Water with Clean and Greasy Plate. (See Durston's Experiments, A and D, Table I.)

The hardness of water is judged by its behaviour with soap in giving effect to the phenomenon called "lathering." Hard water, when used with soap, forms a lather with difficulty; soft water, on the contrary, readily does so. With hard water a considerable amount of soap is used before the lather is formed, and it may be observed that a scum comes on the surface. This scum is formed by the action of the soap in neutralising the salts causing hardness, or, in other words, part of the soap is used or destroyed in softening the water. As previously stated, the salts which chiefly cause hardness are those of calcium and magnesium, and the reaction between soap and one of these may be represented by the typical equation:

$$\underset{\text{Soap or sodium stearate.}}{2NaC_{18}H_{35}O_2} + \underset{\text{Calcium sulphate.}}{CaSO_4} = \underset{\text{Sodium sulphate.}}{Na_2SO_4} + \underset{\text{Calcium stearate Insol. Curdy. ppt.}}{Ca(C_{18}H_{35}O_2)_2}$$

The acid radicle of the soap combines with the calcium to form calcium stearate, a curdy precipitate, which is the scum referred to. Sodium sulphate is also formed, but as this compound does not destroy soap, no hardness is caused by its presence. As has been stated, when hard water is used for washing purposes considerably more soap is required than when soft water is used, just under 1¾lb. of soap being required per 1deg. hardness per 1,000 gallons. Thus, for instance, even when using Dublin Vartry water, which is soft, over 6lb. of soap would be required to soften 1,000 gallons of it before a lather would be formed. Other waters are sometimes used in Dublin, and I have here a sample of water from a well in the city which would destroy about 250lb. of soap per 1,000 gallons before being softened.

Many years ago Dr. Clark took advantage of the fact that waters of different hardness required different quantities of soap

Digitized by Google

to form a lather, and he applied this in his method of estimating the hardness of water. He made a standard soap solution of such a strength that the number of cubic centimetres of it required to produce a lather, when shaken with a given volume of sample water, indicated the degree of hardness of that water. In this country a degree is considered as one grain of calcium carbonate, or its equivalent in other soap-destroying salts, in one gallon of water. In many other countries the hardness is expressed as parts of calcium carbonate in 100,000 parts of water.

Table III. gives the most common soap-destroying salts found in water, also their equivalent values relatively to calcium carbonate—*e.g*, a water containing 1·36 grains of calcium sulphate per gallon would be equivalent to 1·00 grain of calcium carbonate, or 1deg. hardness. The hardness of water may generally be reduced by prolonged boiling. The hardness which is removed in this way is called "temporary" hardness, and that remaining "permanent" hardness, the "total" hardness being the sum of the two.

TABLE III.—Principal Calcium and Magnesium Salts found in Waters.

| Salt. | Symbol. | ‡ Combining weights. |
|---|---|---|
| Calcium carbonate* | $CaCO_3$ | 100 |
| Calcium sulphate† | $CaSO_4$ | 136 |
| Calcium chloride | $CaCl_2$ | 111 |
| Calcium nitrate | $Ca(NO_3)_2$ | 164 |
| Magnesium carbonate* | $MgCO_3$ | 84 |
| Magnesium sulphate | $MgSO_4$ | 120 |
| Magnesium chloride | $MgCl_2$ | 95 |
| Magnesium nitrate | $Mg(NO_3)_2$ | 148 |

REMARKS.—* Held in solution as bicarbonate by presence of $CO_2$. † For solubilities see Fig. 5. All these salts decompose soap. ‡ The combining weights are in this case equal to the molecular weights.

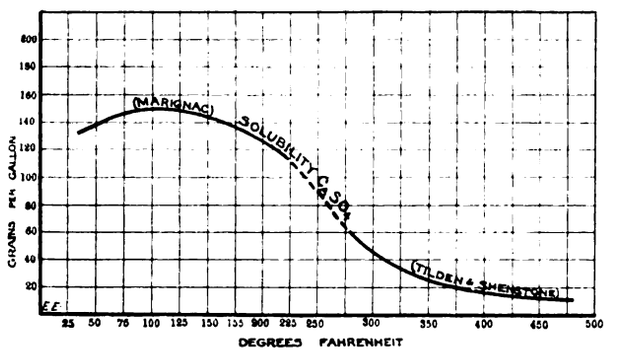


FIG. 5.—Solubility of Calcium Sulphate in Water at Different Temperatures

*Temporary Hardness.*—Temporary hardness is caused by the presence of carbonates of calcium and magnesium, held in solution in the water as bicarbonates by the presence of carbonic acid. By boiling water containing bicarbonate of calcium or magnesium the carbonic acid is driven off, and the insoluble carbonate is precipated thus :

$$\underset{\text{Calcium bicarbonate. Soluble.}}{Ca(HCO_3)_2} = \underset{\text{Calcium carbonate. Insoluble.}}{CaCO_3} + H_2O + CO$$

Where only temporary hardness exists, the water may, therefore, be treated by heating, but the process is costly unless exhaust steam can be used, in which case oil is sometimes introduced into the boiler. About 1½cwt. of coal would be required to heat up 1,000 gallons of cold feed to 212deg. F., and as prolonged boiling is afterwards necessary for complete removal of temporary hardness, it is evident that boiling would not be economical as compared with chemical treatment. With exhaust steam treatment the heating is generally insufficiently prolonged to properly precipitate the carbonates. In some systems, by a combination of heating and introduction of sodium carbonate, both the temporary and permanent hardness are treated.

Table IV. shows approximately the limits of temperature between which certain salts are precipitated by heating the water in which they are dissolved. The carbonates of calcium may also be decomposed by soap, as shown in a previous formula.

TABLE IV.—Approximate Temperatures at which Salts Dissolved in Water will be Precipitated.

| Salt. | Symbol. | Precipitating temp. F°. |
|---|---|---|
| Calcium carbonate | $CaCO_3$ | 180 – 260 |
| Calcium sulphate | $CaSO_4$ | 100 – 430 |
| Magnesium chloride | $MgCl_2$ | 212 – 270 |
| Sodium chloride | $NaCl$ | 330 – 380 |

The most successful and economic method of treating temporary hardness is by Dr. Clark's process. Nearly all patent apparatus of the present day treat the carbonates of calcium and magnesium in this way. The principle of the process lies in the fact that by adding "lime water" (calcium hydrate) to waters containing calcium or magnesium carbonates held in solution by carbonic acid, the lime water combines with the carbonic acid to form calcium carbonate :

$$\underset{\text{Bicarbonate of calcium. Soluble.}}{Ca(HCO_3)_2} + \underset{\text{Lime water. Soluble.}}{Ca(OH)_2} = \underset{\text{Calcium carbonate. Insoluble.}}{2CaCO_3} + 2H_2O$$

The reaction for magnesium carbonate is somewhat different, and may be shown thus :

$$\underset{\text{Magnesium bicarbonate. Soluble.}}{Mg(HCO_3)_2} + \underset{\text{Lime water. Soluble.}}{Ca(OH)_2} = \underset{\text{Magnesium carbonate. Slightly soluble.}}{Mg(CO_3} + \underset{\text{Calcium carbonate. Insoluble.}}{CaCO_3} + 2H_2O$$

The magnesium carbonate produced is only slightly soluble. If, however, twice the quantity of lime water shown in the above equation be added instead, then the second chemical equivalent of lime water acts thus upon the magnesium carbonate produced above :

$$\underset{\text{Slightly soluble.}}{MgCO_3} + \underset{\text{Soluble.}}{Ca(OH)_2} = \underset{\text{Insoluble.}}{CaCO_3} + \underset{\text{Magnesium hydrate. Insoluble.}}{Mg(OH)_2}$$

Magnesium hydrate is produced, and forms as a gelatinous substance which is likely to choke the filters. It is thus not always advisable to add the excess of lime water necessary for converting the magnesium carbonate.

*Permanent Hardness.*—The chief cause of permanent hardness is due to sulphates of calcium and magnesium. Calcium sulphate is soluble in water at ordinary temperatures. Fig. 5 shows that its solubility increases up to about 100deg. F., and then, contrary to general rule, decreases at higher temperatures until at ordinary boiler pressure temperatures it is considerably reduced—*e.g.*, of the calcium sulphate in solution at 100deg. F. only about 17 per cent. would remain in solution at a temperature, corresponding to a pressure of 150lb. per square inch, the remaining 83 per cent. having been precipitated to form incrustation in the boiler. The heaviest deposits obviously occur over the hottest part of the furnace. When such a boiler is cooled down, the calcium sulphate scale will be partly dissolved, and will concentrate in crevices of the scale. On heating up, it will again be deposited in these and cement the whole more firmly than before. This is further accentuated if calcium carbonate is present in the scale.

Magnesium sulphate (better known as Epsom salts) is, as indicated in Table I., a non-scale-forming salt, very soluble, and causes permanent hardness. If this salt is concentrated in a boiler in contact with calcium carbonate scale, the following reaction may take place under certain conditions of temperature:

$$\underset{\text{Calcium carbonate.}}{CaCO_3} + \underset{\text{Magnesium sulphate.}}{MgSO_4} + H_2O = \underset{\text{Calcium sulphate.}}{CaSO_4} + \underset{\text{Magnesium hydrate.}}{Mg(OH)_2} + CO_2$$

The magnesium hydrate formed unites with the calcium sulphate to form a vitreous scale, so that although magnesium sulphate is a non-scale-forming salt, it should not be allowed to concentrate in a boiler on this account.

If water containing calcium sulphate be treated with sodium carbonate, the following reaction takes place :

$$\underset{\text{Soluble.}}{CaSO_4} + \underset{\text{Soluble.}}{Na_2CO_3} = \underset{\text{Soluble.}}{Na_2SO_4} + \underset{\text{Insoluble.}}{CaCO_3}$$

The insoluble calcium carbonate is precipitated and settles down. The sodium carbonate formed remains in solution, and as it does not decompose soap, the water is softened. To prevent concentration of the sodium sulphate or other salts, it is essential that boilers be periodically "blown off." This need not be done more frequently than is usual with properly worked boilers using untreated water.

Magnesium sulphate may be precipitated by treating with lime water, the reaction which takes place being as follows :

$$\underset{\text{Soluble.}}{MgSO_4} + \underset{\text{Soluble.}}{Ca(OH)_2} = \underset{\text{Insoluble ppt.}}{(Mg(OH)_2} + \underset{\text{Partly soluble.}}{CaSO_4}$$

Calcium sulphate is undesirable, and therefore the magnesium sulphate should preferably be treated with sodium carbonate :

$$\underset{\text{Soluble.}}{MgSO_4} + \underset{\text{Soluble.}}{Na_2CO_3} = \underset{\text{Slightly soluble.}}{MgCO_3} + \underset{\text{Soluble.}}{Na_2SO_4}$$

Magnesium sulphate may also be precipitated by the addition of sodium hydrate (caustic soda) with this reaction :

$$\underset{\text{Magnesium sulphate. Soluble.}}{MgSO_4} + \underset{\text{Sodium hydrate. Soluble.}}{2NaOH} = \underset{\text{Magnesium hydrate. Insoluble.}}{Mg(OH)_2} + \underset{\text{Sodium sulphate. Soluble.}}{Na_2SO_4}$$

If, however, lime water and sodium carbonate are added to each other, sodium hydrate is produced :

$$\underset{\text{Sodium carbonate. Soluble.}}{Na_2CO_3} + \underset{\text{Calcium hydrate. Soluble.}}{Ca(OH)_2} = \underset{\text{Calcium carbonate. Insoluble.}}{CaCO_3} + \underset{\text{Sodium hydrate, Soluble.}}{2NaOH}$$

TABLE V.—SHOWING CHIEF SALTS CAUSING TEMPORARY AND PERMANENT HARDNESS AND TREATMENT FOR REMOVAL.

| Hardness. | Cause. | Treatment. | Reaction. |
|---|---|---|---|
| Temporary | Calcium bicarbonate $Ca(HCO_3)_2$ | (1) Boiling | $Ca(HCO_3)_2 = CaCO_3 + H_2O + CO_2$* (Soluble. Insol. ppt.) |
| | | (2) Adding lime water | $Ca(HCO_3)_2 + Ca(OH)_2 = 2CaCO_3 + 2H_2O$ (Soluble. Sol. Insol. ppt.) |
| | Magnesium bicarbonate $Mg(HCO_3)_2$ | (1) Boiling | $Mg(HCO_3)_2 = MgCO_3 + H_2O + CO_2$ (Soluble. Slightly sol.) |
| | | (2) Adding lime water | $Mg(HCO_3)_2 + Ca(OH)_2 = MgCO_3 + CaCO_3 + 2H_2O$ (Soluble. Soluble. Slightly sol. Insol.) |
| | | (3) Adding further lime water | $Mg(HCO_3)_2 + 2Ca(OH)_2 = 2CaCO_3 + Mg(OH)_2 + 2H_2O$ (Soluble. Sol. Insol. Insol.) |
| Permanent | Calcium sulphate $CaSO_4$† | Adding sodium carbonate | $CaSO_4 + Na_2CO_3 = Na_2SO_4 + CaCO_3$ (Sol. Sol. Sol. Insol.) |
| | Magnesium sulphate $MgSO_4$§ | Adding sodium carbonate | $MgSO_4 + Na_2CO_3 = MgCO_3 + Na_2SO_4$‡ (Sol. Sol. Slightly sol. Sol.) |
| | Magnesium chloride $MgCl_2$§ | Adding sodium carbonate | $MgCl_2 + Na_2CO_3 = MgCO_3 + 2NaCl$ (Sol. Sol. Slightly sol. Sol.) |
| | Magnesium nitrate $Mg(NO_3)_2$ | Adding sodium carbonate | $Mg(NO_3)_2 + Na_2CO_3 = MgCO_3 + 2NaNO_3$ (Sol. Sol. Slightly sol. Sol.) |

REMARKS —* $CaCO_3$ if precipitated slowly, as in economisers, forms a hard scale; if the precipitation is rapid, as in boilers, the deposit is in the form of mud. † $CaSO_4$ forms no scale in economisers, but a hard scale in boilers (see Fig. 5). ‡ $Na_2SO_4$ does not decompose soap. § These three salts are liable to cause corrosion; if it is desired to convert the slightly soluble $MgCO_3$ to the insoluble $Mg(OH)_2$, lime water may be added with the sodium carbonate, the typical reaction then being:

$$MgSO_4 + Na_2CO_3 + Ca(OH)_2 = Mg(OH)_2 + CaCO_3 + Na_2SO_4$$
(Sol. Sol. Sol. Insol. Insol. Sol.)

As both sodium carbonate and lime water are used in treating other salts, their presence may be taken advantage of for the precipitation of the magnesium sulphate—thus:

$$MgSO_4 + Na_2CO_3 + Ca(OH)_2 = CaCO_3 + Mg(OH)_2 + Na_2SO_4$$

Chlorides and nitrates of calcium are likewise acted upon by sodium carbonate alone, or by sodium carbonate + calcium hydrate.

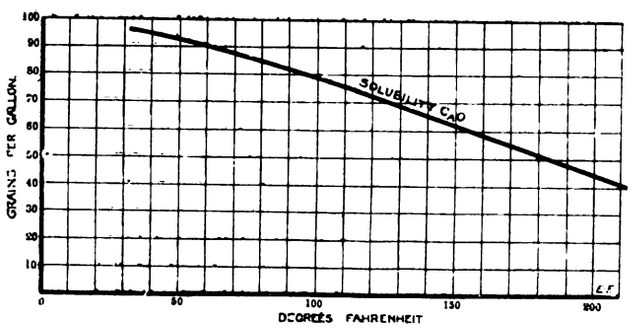

FIG. 6.—Solubility of Lime in Water at Different Temperatures. (Lunge.)

It will be observed that the salts in water which are the chief cause of temporary and permanent hardness are removed by two reagents only—viz., lime water and sodium carbonate. The lime may be added in the form of lime water, which is the clear liquid obtained by dissolving lime (CaO) in water, or by "slaking" quicklime with excess of water. Fig. 6 shows that lime is not very soluble in water, even at its maximum solubility. It can, however, be added to less water than is required to entirely dissolve it, and if the whole be kept stirred or agitated a milky fluid known as "milk of lime" is obtained, which may be used in softening water. Both lime and carbonate of soda are inexpensive and easily obtained. The latter is used in the form of "soda ash."

Table V. shows a summary of the chief causes of temporary and permanent hardness and means of removing these. It will be observed that the last three magnesium salts are acted on by sodium carbonate, producing the partly soluble magnesium carbonate. Caustic soda, if used as a reagent, produces the insoluble magnesium hydrate. The latter reagent, as previously stated, is formed by the combination of lime water and sodium carbonate.

The quantities of reagents required to treat a water can be found from the molecular weights of the hardening salts (see Table III.), and the reactions given in Table V. Thus 0·56 grains of lime are required to precipitate one grain of calcium carbonate, or, in other words, 0·56 grains of lime are required for each 1deg. of temporary hardness per gallon, or 0·081b. for each 1deg. per 1,000 gallons. With lime at 20*s.* per ton, the cost would be 0·00856d. per 1deg. per 1,000 gallons. In the same way 0·1521b. sodium carbonate would be required for each 1deg. of permanent hardness, and this at £4 per ton would amount to 0·06491. per 1deg. per 1,000 gallons. Each degree of permanent, therefore, costs over 7½ times as much to remove as each degree of temporary hardness, or 1,000 gallons with 58deg. temporary hardness costs for lime ½d., and 1,000 gallons with 7·7deg. permanent hardness costs for soda, ½d.

Most water softeners consists of the following: (1) tanks or vessels for containing the chemicals or reagents; (2) apparatus for distributing the chemicals in their proper proportions; (3) tank or vessel in which the hard water is treated; (4) filters for retaining the precipitates formed. The distributing apparatus should be automatic in regulating the supply of reagents according to any variation which may occur in the quantity of hard water requiring treatment, and should also be capable of being readily adjusted should the hardness of the water vary. The filters should also be designed for rapid and efficient cleansing with minimum delay in the working of the plant should renewals of filtering medium (which generally consists of either wood wool, sponge, cloth, or sand) be required. Some filters are made in sections, each of which can be by-passed when cleaning, thus enabling the filters to be cleaned without interrupting the work.

Below are the results of tests I have made on the hardness of three Dublin waters:

| | Vartry. | Canal. | Well. |
|---|---|---|---|
| Temporary hardness | 0·55 | 10 0 | 20 0 |
| Permanent hardness | 3·35 | 5·0 | 130 0 |
| Total hardness | 3 90 | 15·0 | 150 0 |

*Purification.*—The injurious effects of oil introduced into a boiler have already been pointed out. If the condensation water from the condenser of an engine be collected in a glass vessel and examined, it will be found to have a milky appearance, due to the presence of minute globules of emulsified oil in suspension. These globules, if allowed to enter the boiler with the feed water, to a large extent adhere to the plates. How a thin film of oil on a boiler plate should hinder heat transmission to such an extent as to become dangerous is a subject which has been the cause of much discussion. To obviate risk, the condensed steam may be run to waste and fresh feed water used. Assuming this is done in a station with an average output of 500 kw., the steam consumption being equal to about 1,000 gallons of water per hour at 6d. per 1,000 gallons, equals

Digitized by Google

12s. per day, or over £200 per annum. This only represents about one-half the saving, as, before a comparison can be made, the cost of heating up the cold feed to the temperature of the condensed steam, say 100deg. F to 130deg. F., would have to be taken account of. As the cost of working a purifier is very small, a total saving is effected worth serious consideration.

Oil in the exhaust steam on the way to the condenser cannot be completely arrested, neither can it be separated from the condensation water by mechanical filtration. The globules of emulsified oil are of such minute dimensions that they will pass through filter paper as easily as through the finest-woven fabric. Fig. 7 shows diagrammatically a comparative ratio between the size of a mesh of fine fabric and that of a particle of emulsified oil.

The most successful method of satisfactorily eliminating oil in this condition is by chemical means. Chemicals are introduced into the condensation water. This brings about a reaction which envelopes the oil particles with a precipitate, causing them to adhere together in sufficiently large groups to render filtration easy; the resulting filtrate being perfectly clear. The reagent generally used is aluminium hydrate ($Al_2(OH)_6$), readily prepared by the interaction of sodium carbonate on aluminium sulphate:

$$Al_2(SO_4)_3 + 3Na_2CO_3 + 3H_2O = Al_2(OH)_6 + 3Na_2SO_4 + 3CO_2.$$

The sodium carbonate and aluminium sulphate are added to the condensation water, and form the aluminium hydrate precipitate which surrounds the oil particles.

Another method of purification recently tried is by electrolysis, whereby the emulsified condensation water is used as an electrolyte. Electrodes are introduced into this, the current acting upon and precipitating the oil in such a form that it can afterwards be filtered.

The essential parts of chemical purifiers are similar to those already mentioned for softeners.

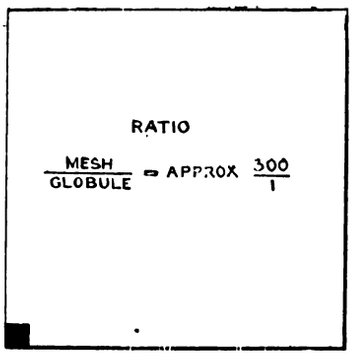

FIG. 7.—Approximate Ratio of Area of Mesh of Fine-Woven Fabric to average size of Globule of Emulsified Oil in Condensation Water.

It would scarcely be possible in this paper to describe the numerous water softeners and purifiers on the market, but anyone desirous of investigating the working of the former will find valuable information in a recent paper on the subjects by Messrs. Stromeyer and Baron (*Proceedings*, Institution of Mechanical Engineers, 1903, p. 773).

## PHYSICAL SOCIETY.

At a meeting of this society on April 14, Dr. R. T. Glazebrook, F.R.S. (vice-president), in the chair,

A paper on "*The Determination of the Moment of Inertia of the Magnets used in the Measurement of the Horizontal Component of the Earth's Field*" was read by Dr. W. WATSON. One of the constants required when determining the horizontal component of the earth's magnetic field by the ordinary method is the moment of inertia of the magnet which is used in the vibration experiment. It is usual to determine the moment of inertia of the cylindrical brass bar supplied with each instrument by calculation, then by measuring the period of the magnet alone, and when loaded with this bar to calculate the moment of inertia of the magnet. This method presupposes that the density of the inertia bar is uniform throughout. It is not easy to secure a bar of which the density is uniform throughout, and, further, it is difficult to test whether such uniformity has been secured. The author thinks that more reliable and uniform results would be obtained by determining once for all, with very great care, the moment of inertia of a standard bar and then determining the moment of inertia of the bars supplied with the different magnetometers, by comparing them with the standard bar experimentally. In the paper is described an instrument suitable for comparing the moment of inertia of bars, together with some experiments made with a view to determining the moment of inertia of a standard bar, and an investigation of the influence of the air upon the period. The bars which have been compared are as follows: (1) rolled brass; (2) cast silver; (3) rolled copper; (4) copper with 5 per cent. zinc; (5) copper with 5 per cent. phosphide of tin; (6) gunmetal; (7), (8), (9) rolled copper; and (10) a rolled brass bar with slightly rounded ends and gilt. The periods of oscillation of the bars when resting in a cradle hung by a quartz fibre were determined accurately with the instrument described. Owing to the fact that the rigidity of fused silica increases as the temperature rises, the period changes very little with temperature and the corrections for changes in temperature can be made without difficulty. With an initial amplitude less than 5deg the period is not, within the limits of accuracy of the observations, affected by the variation in amplitude. Variations in period due to the variation of the rigidity of the fibre with the load upon it were found to be negligible. In order to test the influence on the period of the air carried by the bars when swinging, a vacuum chamber was used which enclosed the whole instrument. The procedure adopted was to observe the period at atmospheric pressure, then exhaust and observe the period, and, finally, the air having been readmitted, to observe again at atmospheric pressure. The results showed an increase of moment of inertia for 76cm. increase in pressure of the order ·1 per cent. The author has investigated the effect of the air in the case of the magnets used in the Kew pattern unifilar magnetometer, and finds that it may cause an error of about 4·4 γ. The paper concludes with a comparison of Dr. Watson's bars with some belonging to the National Physical Laboratory.

Dr. C. CHREE expressed his interest in the paper, and remarked that the want of homogeneity in inertia bars was a source of serious trouble in magnetometer work. The variation in density might be as much as 5 or even 10 per cent. He favoured the adoption of a standard bar which could be swung in various magnetometers. He expressed his interest in the size of the error which may affect the value of the horizontal force due to the increased moment of inertia caused by the air. A similar error entered into pendulum observations. With regard to the rigidity of quartz fibres, he was inclined to think that there would be a change in rigidity with a change in load.

Mr. W. A. PRICE asked if the difference in magnetic permeability between air and the material of the bars was sufficient to affect the period, and also if there were any other fibres whose rigidity increased with rise of temperature.

The CHAIRMAN expressed his interest in the paper, and said that he had followed the course of the work. In attempting to get an accurate value for H it was most important to check the homogeneity of the inertia bar. The value of the moment of inertia should be known with great accuracy. Four or five years ago he suggested experiments similar to those described by Dr. Watson for measuring inertia bars, and although preliminary observations were made they were not carried far.

Dr. WATSON said he knew of no other substance but quartz which was suitable for the experiments he had performed. He had not found any variation of period due to magnetic permeability. With regard to Dr. Glazebrook's remarks, he said the measurement of the diameter of the bars was easy, but that the determination of the length was much more difficult.

Dr. W. WATSON gave an "Exhibition of a Series of Lecture Experiments illustrating the properties of the gaseous ions produced by Radium and other Sources." Many well-known experiments on the subject were shown by Dr. Watson, who pointed out the precautions which must be observed in order to ensure success at lecture demonstrations.

## LEGAL INTELLIGENCE.

### OBSTRUCTING A CAR.

At the Spelthorne Petty Sessions last week, George Fearnham, of High-street, Teddington, baker's assistant, was summoned by the London United Tramways Company for obstructing a car when driving a horse and cart at High-street, Teddington, on March 4 and on March 23.

It appeared that accused had been in the habit for a long time of deliberately placing his van so that the wheels projected over the tramline. Defendant had been spoken to by a police officer, but he refused to move his van. On the first day in question he delayed a car eight minutes, and on the 23rd he repeated such conduct in an aggravated form. On that occasion a gentleman pulled the van aside, whereupon defendant deliberately placed the van again in the position complained of, and further delayed the car.

Several witnesses corroborated the facts, one deposing to a statement by the defendant that it was allowable to stop a vehicle for 20 minutes, which he intended to do. There was quite enough room for the van to have passed the car.

Mr. ROBINSON, for the defence, said that a cart had a right to stop for loading and unloading for a reasonable time irrespective of obstructions. There had been no trouble till the trams came along. The company had agreed with the Teddington Urban District Council to widen the road, but this had not been done.

The CHAIRMAN: That has nothing to do with this case.

Mr. ROBINSON said the question was whether there was room or not.

The CHAIRMAN said they had it in evidence that there was ample room for the cars to pass.

Mr. ROBINSON: That is their opinion.

The CHAIRMAN: This van had been passed time after time.

Mr. ROBINSON: If the doors are open the tramcars can't pass.

The CHAIRMAN: Nothing should project on a cart beyond the hubs.

Mr. ROBINSON: Then every load of hay would be against the law.

The CHAIRMAN: We are not trying that now.

The Bench were unanimously of opinion that it was a case of wilful obstruction to cause annoyance. Defendant would be fined £2. 10s. on each summons, including costs. If such obstruction were again proved against him, he would be fined the full penalty with costs.

# COMPANIES' MEETINGS AND REPORTS.

## BRUCE PEEBLES AND CO.

The annual meeting of this Company was held at the offices of the Company, Edinburgh, Mr. W. Carmichael Peebles (the chairman) presiding. Particulars of the report appeared in our issue of the 31st ult.

The CHAIRMAN, after reviewing the satisfactory position, said that the increase in trade was being maintained in the current year. Although the progress of the Company's electrical interests had overshadowed other branches the gas business had also done well, the "penny-in-the-slot" meter having proved of great value.

The report was unanimously adopted.

Mr. A. W. Tait was elected and Messrs. A. C. Peebles and Roland S. Portheim re-elected directors.

Extraordinary general meetings of the Company and also of the preference shareholders were afterwards held, at which resolutions were unanimously carried authorising the increase of the capital from £200,000 to £300,000, by the creation of a further 10,000 6 per cent. cumulative preference shares of £5 each, and 10,000 ordinary shares of £5 each. Resolutions were also passed authorising an increase of the borrowing powers of the Company from £50,000 to £100,000. It is not intended to exercise the increased borrowing power at present.

## METROPOLITAN ELECTRIC TRAMWAYS, LIMITED.

The report for the year ended Dec. 31 showed that the total revenue amounted to £113,254 including the dividends on shares held in the North Metropolitan Tramways Company and the Harrow-road and Paddington Tramways Company, and interest upon the advances made to the North Metropolitan Electric Power Supply Company. The gross traffic receipts amounted to £81,843, as compared with £66,973 for the previous year. As the lines now working by electric traction were not opened until the second half of the year, and some of them not until December, the directors consider the increase of traffic receipts satisfactory. The revenue account, after deducting all expenses chargeable to revenue, including loan and debenture interest, shows a surplus of £32,283. Deducting the full dividend on the preference shares for the year, amounting to £25,000, and providing for the repayment to the British Electric Traction Company, Limited, of the balance due to them for the advance made in January, 1903, under their guarantee of the preference share dividend, there remains an available balance of £3,854, which the directors recommend should be carried forward. The directors propose to make an issue of ordinary shares at par to the holders of all classes of shares and to the debenture stock holders on the registers of the Company on April 7, 1905, in the proportion, as nearly as practicable, of one ordinary share in respect of every 10 shares or £10 debenture stock held at that date. It is proposed to make the shares payable by instalments of 5s. on acceptance of allotment, 5s. one month later, and 10s. two months later.

At the ordinary general meeting last week Mr. EMILE GARCKE, who presided, said that during the past year the Company had carried about 9,500,000 of passengers by horse cars and about 7,500,000 by electric cars, amounting to about 17,500,000 in all. On the horse lines the average receipts were 10·8d. per car mile and on the electric line they averaged about 13·3d. per car mile, and taking the receipts per route mile on the horse lines, they were able to take about £8,000 per route mile per annum and on the electrical part of the tramways close upon £14,000 per route mile per annum. They were busily engaged in completing the conversion of the remainder of the horse lines, and the Middlesex County Council were constructing, and this Company equipping, various light railway routes, and it was hoped that about 4½ miles of light railways would be open before Whitsuntide on what was known as the Great North-road, from Highgate Archway to Finchley, thus serving a very populous district which had not hitherto been opened up by tramways. In connection with that particular route, he referred to an important arrangement which the Company had been able to effect with the London County Council. The present horse tramways in the direction of the Highgate Archway fell short of the commencement of their light railway by about half a mile this side of the Highgate Archway. It was, therefore, very important that that link should be completed, and they had been able to arrange with the London County Council to construct that piece of line, which would be leased to their Company, so that they would be able to start electric cars at the point where the present horse lines terminated. Another very important route, which would be in operation at any rate before the summer, was that leading direct to the Alexandra Palace. Two other important arrangements had been effected with the Wood Green local authorities and the authorities of Edmonton, both providing for the extension of the Company's tenure, these authorities agreeing not to exercise their rights of purchase of these lines until 1930. Referring to the reported proposal of the London County Council to purchase the unexpired term of the lease held by the North Metropolitan Tramways Company, the Chairman remarked that their Company was very largely interested, as shareholders in the North Metropolitan Tramways, but this matter had not as yet come officially before them. The matter was still under negotiation, but there would be no harm in his making a general statement as to how it affected the Company otherwise than financially. Practically, it would anticipate the normal course of events, and if the lease were continued until 1910 they would continue to receive their dividends at the rate of 3¾ per cent.; but at the end of that time the Company would receive a payment in respect to the sale of the horses and cars to the London County Council. The Bill which they promoted in the last session of Parliament for the purpose of completing the purchase of the Harrow-road and Paddington undertaking, and to carry out the conversion to electric traction, was confirmed by Parliament, and they were therefore in the position of being virtually the owners of that undertaking though they had not yet completed the purchase. So strongly did the directors feel the importance of losing no time in the electrification of the undertaking that they were very seriously contemplating the raising of some additional capital for the purpose at a very early date.

In connection with the various ambitious schemes in existence for the supply of electrical power, the CHAIRMAN stated that their Company was already very well situated for doing that particular work, and their area was not affected by the Administrative County Company's Bill. Having alluded to the proposed issue of ordinary shares, mentioned above, he concluded by moving the adoption of the report.

Sir ERNEST SPENCER, M.P. (deputy-chairman), seconded the resolution, which, after a short discussion, was unanimously carried.

The retiring directors (Mr. G. Richardson and Mr. J. Goddard) were duly re-elected, and the meeting closed with a cordial vote of thanks to the chairman and directors for their able services during the past year.

## BARCELONA TRAMWAYS.

The annual meeting was held on Monday at Winchester House, Mr. J. B. Concanon presiding.

The CHAIRMAN, in moving the adoption of the report (of which we gave particulars last week), said that the Ensanche line, for the first time since its electrification, had not only earned the full interest on this Company's large loan to that undertaking, but had also shown a surplus on working of nearly £700, which had gone in reduction of the loan itself. With regard to the outlook, the earnings this year, to the end of March, were more by £4,621 on the Barcelona system, and he thought that £4,000 of this amount would be retained as net profit. Provided that for the rest of the year there was no falling off in the receipts, and that the rate of exchange remained as it was, they should be between £6,000 and £7,000 better off at the end of 1905 than they were at Dec. 31 last. Against this, however, nearly £5,000 would have to be expended on relaying a certain portion of the system, and the directors contemplate voting a substantial sum to their colleague Mr. H. Brown for his special services to the Company. Negotiations were at present in progress with the Municipality of Barcelona for the unification of their concessions. In view of the improved financial position of the Company, the Board hoped to be able to declare an interim dividend on the ordinary shares in the autumn.

The report was unanimously adopted.

## PRIMITIVA GAS AND ELECTRIC LIGHTING OF BUENOS AYRES.

The balance of revenue account for 1904 and the interest received from the German Transatlantic Electricity Company amount to £115,386, and transfer fees to £72, making a total at the credit of profit and loss account of £115,458. Adding the balance brought forward from the previous year of £16,613 there is a grand total of £132,071. After deducting the various charges and placing £15,000 to reserve, there remains a balance of £40,469 to the credit of profit and loss. The directors recommend that a dividend of 6s. per share (free of income tax), equal to 6 per cent. for the year, be declared on the ordinary shares of the Company, which will absorb £24,000, leaving £16,469 to be carried forward to next year's account. The service and redemption at par of the whole of the authorised issue of debentures is provided for in the agreement of Aug. 12, 1903, with the Deutsch Ueberseeische Electricitäts-Gesellschaft of Berlin, the particulars of which were given in the previous report of the directors. The Company's works have been maintained in efficient repair. An additional sum of £1,500, over and above the annual minimum of £2,500 previously agreed to, has been added to reserve against discount on debentures and expenses of issue. The increase in sales of gas during the past year amounted to 4½ per cent., and there has been considerable growth in the use of cookers and stoves. The Company were affected by the workmen's strikes in Argentina.

## WYCOMBE ELECTRIC LIGHT AND POWER.

The report for the year ended Dec. 31 states that considerable progress has been made by the Company during the year, the connections having risen from 31,930 to 37,383, being an increase of 5,453 equivalent 8-c.p. lamps. The result of the year's trading, including a balance of £93. 5s. 8d. brought forward from the previous year, shows a profit to the credit of the net revenue account of £3,854. 19s. 2d., and, after paying interest on debenture and loans amounting to £2,122. 5s. 10d. (including £100 written off for bad debts), there is a surplus of £1,825. 19s. The directors recommend the payment of a dividend at the rate of 4 per cent. for the year, which will absorb £1,200, and that £500 be placed to the reserve fund for renewal of plant, leaving a balance of £125. 19s. to be carried forward to next year's account.

## APPOINTMENTS VACANT.

**Premium Pupil**, Cork. 52 guineas. See advertisement.

**Foreman** of switch and controller department. See advertisement.

**Switchboard Attendant**, Swindon Corporation electricity and tramways department. Wages 25s. per week. Applications by May 3. See advertisement.

Digitized by Google

## CONTRACTS FOR ELECTRICAL SUPPLIES.

**Govan.**—The Council require annual stores. Tenders by 25th inst.

**Portsmouth.**—The Council require annual stores for tramways. Tenders by May 1.

**Dublin.**—The Port and Docks Board invite tenders for an electric generating station. Tenders by May 15.

**Wallasey.**—The Council require annual supply of stores for their electricity works. Tenders by 27th inst.

**Bournemouth.**—The Town Council invite tenders for Contract No. 6—11 electric cars. Tenders by 29th inst.

**Edinburgh.**—The Corporation invite tenders for water-tube boilers. Tenders by May 8. See advertisement in last issue.

**Cataquoxes (Spain).** — The local light and power company require tenders for electrical plant. Tenders by July 1.

**Montreal.**—The Montreal Water and Power Company, 107, St. James-street, require tenders for machinery for a pumping station.

**Johannesburg.**—The time for sending in tenders for this contract (particulars of which appeared in former issues) is May 8 (London).

**Paris.**—The Government Railways, rue de Chateaudun 42, Paris, require tenders for copper strip, lighting accessories, etc. Tenders by 2.30 p.m. on April 27.

**Cork.**—The Cork Electric Tramways and Lighting Company, Limited, invite tenders for the supply of white wood casing and capping. See advertisement.

**Stockport.**—The Gas and Electricity Committee invite tenders for the supply of one 500-kw. steam generator. Tenders by April 26. See advertisement in last issue.

**Liria.**—The Municipality require tenders for installation of electric lighting; 2,000 c.p. are required for street-lighting, for which it is proposed to pay 6,000 pesetas per annum.

**Dax (Province of Landes, France).**—The Municipality require tenders for their concession to erect and work electric lighting for 35 years. Tenders to the Mayor by May 14.

**French West Africa.**—The Governor-General of French West Africa, at Dakar, requires tenders for the erection and equipment of a central station at that place. Tenders by May 15.

**Bilbao.**—The Public Works Department at Madrid require tenders for the concession of an electric tramway in Bilbao, from the Calle de Hurtado de Amézaga to Plaza Circular. Tenders by April 24.

**Laventhem (Belgium).**—The Municipality require tenders for erection of central station, laying of mains, etc. Particulars (3s. 4d.) may be obtained from the Secretary of the Mayor of that place.

**Bournemouth.**—Tenders are invited for the following, for the Corporation Tramways (Christchurch extension): Contract No. 5—feeder cables, troughing, excavation, etc. Tenders by April 29.

**Fulham.**—The Council invite tenders for condenser piping, sump and river work, steel roof and bunker work, and coal-conveying apparatus. Tenders by 25th inst. See advertisement in last issue.

**Wimbledon.**—The Urban District Council invite tenders for the supply and erection of a 1,000-kw. steam-driven turbo-alternator, with condensing plant, high-tension switchgear, and pipework. Tenders by April 28.

**Antwerp.**—Tenders will shortly be invited by the Belgian State Railways for the installation of electric light in their local railway station. Specification No. 619 may be obtained from the Government Railways Office, Brussels.

**Bristol.**—The Docks Committee invite tenders for the construction, delivery, erecting in place, fitting, testing, and maintenance for 12 months after completion of two electric goods lifts and one electric passenger lift. Tenders by May 1.

**New Ferry (Cheshire).**—The Lower Bebington Urban District Council invite tenders for the work of electric installation for fire brigade alarm in New Ferry, and also for supply of street lanterns for incandescent lighting. Tenders by April 24.

**London.**—The London County Council invite tenders for the supply, erection at its generating station, East Greenwich, S.E., and maintenance for a period of 10 years, of a battery of 280 accumulator cells having capacities of 645 ampere-hours at a three-hour discharge rate and of 450 ampere-hours at a one-hour discharge rate. Tenders by May 16. Full particulars in advertisement columns.

**Switzerland.**—M. R. Vontobel, of Winterthour, and M. Charles Probst, of Lucerne, have obtained a concession for the construction of a narrow-gauge electric railway from Meiringen to Gletsch. The total cost of the enterprise is estimated at £241,600; £19,600 is to be expended on rolling-stock.

**London, N.**—Tenders are invited for the road work, platelaying, and paving, etc., required for the construction for electrical traction on the overhead trolley system of the short length, equivalent to about three-fourths of a mile of single track, of authorised tramway in Archway road, Highgate, between the Archway Tavern and the Highgate Archway, in the metropolitan borough of Islington, for the London County Council. Tenders by May 8.

## RESULTS OF TENDERS.

**Rochester.**—The Town Council have accepted the tender of the National Telephone Company for fixing telephones between the various offices and the Council chamber at £24.

**Sunderland.**—The Corporation have accepted the tender of the Phœnix Dynamo Manufacturing Company, Limited, Thornbury Works, Bradford, for the supply of four 250-kw. synchronous three-phase motor-generators.

**St. Marylebone.**—The Electricity Supply Committee recommend the Council to accept the tender of the St. Helens Cable Company, Limited, for the supply, erection, and connecting up of 880 yards of 2 sq. in. and 440 yards of 1 sq. in. fire-resisting cables for £1,381.

**Hoylake.**—The order for a 250 kw. steam alternator has been placed with the British Thomson-Houston Company, Limited, at £1,407, with Browett, Lindley and Co., Limited, as sub-contractors for the engines. The delivery is to be made within 19 weeks. The alternator efficiency is given as follows: full load 92½ per cent., three-quarter load 91 per cent., half load 87½ per cent.

**Fulham.**—The Borough Council have accepted the following tenders for the supply of electrical stores for year ending March 31, 1905; W. H. Willcox and Co., asbestos goods; J. Gibb and Co., rubber goods and street-lighting (with the exception of arc lamp globes); General Electric Company, carbons; British Insulated and Helsby Cables, Limited, service boxes (with the exception of house fuse boxes).

**Hammersmith.**—On Wednesday the Electricity Committee recommended that the tender of G. and J. Weir for the feed-water pumps, at £108, be accepted. They also reported that tenders for supplying the arc lamp accessories required during the year were invited with those for the other electrical stores, but as no tender was received, the engineer had obtained a quotation from the Universal Electrical Manufacturing Company, of Peckham, and had reported that the value of the goods required will amount to about £25 during the year. The committee recommended that the goods be obtained from that company. They also submitted the following tenders:

Flues and forced draught.

| British Electric Plant Company, Alloa, N.B. | 18 728 | 0 | 0 |
| Johnson and Phillips, London | 19,817 | 0 | 0 |

(5) For the supply of the general electric wiring material required for the Greenwich electricity generating station:

| | | | |
|---|---|---|---|
| Conduits and Fittings, Limited, London* | £1,407 | 0 | 0 |
| General Electric Company, Limited, London | 1 413 | 13 | 11 |
| Armorduct Manufacturing Company, Limited, London | 1,423 | 14 | 9 |
| Edison and Swan United Electric Light Company, Limited, London | 1,424 | 16 | 0 |
| W. McGeoch and Co., Limited, London | 1,480 | 0 | 9 |
| Simplex Steel Conduit Company, Limited, Birmingham | 1,697 | 11 | 11 |
| Verity's, Limited, London (incomplete) | 1,144 | 4 | 0 |

Conduits and Fittings, Limited, to be allowed to sublet to Spagnoletti and Co., London, or to such other person or firm as may be approved by the engineer under the contract, the supply of certain of the electrical fittings.

* Recommended for acceptance.

**Sports.**—The Electrical Trades Union (London District) have formed an athletic club under the title of "Eltradion," the name of the official journal of the society. They would like to arrange cricket matches with clubs connected with electrical firms. They describe their calibre as "25; weak." The secretary is Thos. Grover, 108, Hall-road, Peckham.

# BUSINESS NOTES.

## TRACTION.

**Dover.**—The work on the tramway at River is progressing rapidly.

**Blackpool.**—The new double line of tramway is expected to be running for Easter.

**Yarmouth.**—Two additional cars are to be purchased for the Corporation tramways.

**Derby.**—It is expected that the contractors will start upon the construction of the Kedleston-road and Normanton extensions at the beginning of next month.

**British Columbia Electric Railway Co.**—The directors have declared an interim dividend on the deferred ordinary stock at the rate of 6 per cent. per annum for the half-year ended Dec. 31.

**Coventry Electric Tramways Co.**—A dividend of 2 per cent. for the year 1904 is recommended by the directors in their report, and the transfer of £500 to reserve, leaving £646 to be carried forward.

**Swansea.**—A trial trip was made on the Morriston section last week. The Corporation engineer, Mr. Prusmann, expressed himself as quite satisfied with the test, which was rather a severe one.

**Cartagena.**—The Tramways de Carthagéne, a Belgian company, with offices at 80, Rue du Nord, Brussels, have obtained the permission of the Spanish Government to introduce electricity in the whole of their system.

**Bradford.**—The Board of Trade have given the Corporation sanction to construct a double line, about 1¾ miles in length, between North Bierley and Wyke, and another, about a mile in length, from Huddersfield-road to the boundary at Hipperholme.

**Isle of Wight.**—A public service of motor omnibuses for the Isle of Wight, arranged by the Isle of Wight Express Motor Syndicate, has been inaugurated at Ryde, Lady Adela Cochrane, wife of the deputy-governor of the island, driving the first car round the Canoe Lake.

**Edinburgh.**—A provisional order seeking, among other things, the construction of an electric tramway along Gilmore-place to Colinton was considered by the Town Council last week, but as no instructions were given for the order to be lodged, it will now have to stand over till November.

**Belfast.**—The Belfast United Trades and Labour Council have passed the following resolution: "That no arrangement of stages and fares on the new electric system will be satisfactory to the working classes of the city which does not include ½d. fares for stages of at least one mile in length."

**Radcliffe.**—The Urban District Council have agreed upon fares with the Bury Corporation in view of the two systems being linked up shortly. It is probable that the Electricity Committee will shortly come to a decision with reference to the purchase of another engine set, so that a fair margin of energy may be available.

**Chilian Electric Tramway and Light Co.**—The directors have received a cablegram from Santiago de Chile advising them that the profit of the lighting department of the company for the month of March, 1905, is 30,162dol., instead of 24,153dol. The total profit of the company therefore will be 104,176 dol., instead of 98,166dol., as previously stated.

**Baker-street and Waterloo Railway.**—This Bill came before the Unopposed Bill Committee of the House of Commons last week. The object of the Bill is to allow of new subways, an extension of time for the compulsory purchase of land, and the payment of interest out of capital during construction. The preamble was formally proved, and the Bill ordered to go forward.

**West Cumberland.**—The West Cumberland Tramways (Extension of Time) Bill, which has already been passed by the House of Lords, came on before the Examiners of the House of Commons for proof of compliance with the further Standing Orders. There was no opposition at this stage, and the necessary formal proofs having been given the Examiners decided that the further orders had been duly complied with. The Bill will therefore be reported for second reading.

**Halifax.**—A preliminary statement of receipts during the past year puts the takings at £74,019, or 11 53d. per car mile run, the aggregate number of car miles run being 1,540,707. In the previous year the receipts were £68 208 6s. 3d., or 11 79d. per car mile run. The present length of route open is 35½ miles, which is 2½ miles more than 12 months ago. The energy consumed was 3,009,940 units, or 1·94 units per car mile, compared with 1·87 units per car mile in the year 1903-4.

**Cardiff.**—At a meeting of the Tramways Committee last week the engineer, Mr. Ellis, reported that during March they had carried 44,180 more passengers, had run 10 985 fewer car miles, and there had been £130 less expenditure and £335 more profit, making a total increase in profit for the month over March of last year of £466. These figures were received with gratification, and it was remarked that they were justification of the recent rearrangement of the tramway service.

**Edgware-to-Hampstead Railway.**—Last week the Committee of Ways and Means considered this Bill, to which there was no opposition. The Bill authorises the construction of a deviation railway at Hampstead to join up with the Charing Cross and Hampstead Railway, and it also empowers the company to enter into agreements with the Underground Electric Railways Company for the construction of works and supply of current. There was no opposition, and the Bill was ordered to go for third reading.

**Leeds.**—The annual tramway report (of which we recently gave an outline) will come before the committee in a fortnight. The profits will approximate to £56,000. This figure has been arrived at on a similar basis to that adopted in previous years—*i.e.*, full allowance has been

Digitized by Google

made for depreciation. A sum of £6,000 more than was estimated has been spent on renewals and the maintenance of the permanent way, in pursuance of a policy by which the whole of the system is maintained in the highest state of efficiency.

**Croydon.**—Interesting statistics have been compiled regarding the Croydon tramways, which since their electrification have been worked under lease from the Corporation by the British Electric Traction Company. During the last three years of the old horse cars 10 000 000 passengers were carried, but during the three years of the electrified system 40 000,000 have been carried. In the last 12 months the population of Croydon, about 145,000, has been carried almost 100 times over. In one year £20,000 was absorbed in wages, while the taxes paid totalled £2,120.

**Leith.**—At a meeting of the Tramways Committee last week it was decided to relay the section from the foot of Leith Walk to Pilrig at an estimated cost of £3,000. This section was relaid four years ago at a cost of several thousand pounds, and it was hoped that the heavy rails then laid would suffice for the new system now being installed. The rails were bonded for electricity, iron connections being placed between the two rails at suitable intervals. It is now found, however, that the part of the rails on the inner side of the groove is so much worn that they are quite unsuitable for the new cars.

**Rothesay.**—Before Sheriff Martin at Rothesay last week the Buteshire County Council and the Bute District Committee applied for an interim interdict against the Rothesay Tramway Company proceeding with the work of extending the line to Ettrick Bay until they had completed their agreement to purchase the greens in front of Port Bannatyne village for the extension of the roadway. For the company, it was pointed out that the owners refused to sell, and that the company had statutory powers for proceeding. The sheriff declined to grant an interim interdict, and adjourned the further claims for interdict and restoration of the roadway till the first ordinary court on May 11.

**Heckmondwike.**—On the consideration of the Urban District Council's Improvement Bill it was stated that a sum of £15 000 was needed to extend the electricity works, so as to supply energy to the tramway company. Part of the money had been spent in advance. The Council were bound to complete the agreement with the tramway company, and were anxious to do it as soon as possible. The chairman said the committee would not think of giving them powers to raise so large a sum of the capital on such evidence as was put before them. The utmost the committee would do would be to give such a sum of money as the Local Government Board might, on enquiry, approve.

**Dalkeith.**—At the monthly meeting of the Town Council the draft agreement between the Council and the Suburban Electric Tramways was considered, and it was agreed to forward the same for the approval of the directors. A clause was inserted giving the Council power to control the Sunday traffic. The other conditions proposed include a provision that the company shall within one year from the date of the passing of the provisional order substantially commence the work of laying down the tramways, and within two years have the same open for the conveyance of passengers. There is a limitation that the fares shall not exceed 1d. per mile, and that on workmen's cars the charge will not be above half that rate.

**Kirkcaldy.**—It is reported that Mr. Wemyss has decided to form a company to carry on the tramway scheme. At the enquiry in Edinburgh in connection with the tramways Mr. Wemyss stated he intended to retain the concern entirely in his own hands. The Home Office intimated that he must form a statutory company within two years, and hand over the concern to it. In view of this Mr. Wemyss has resolved to float a company with a capital of between £60,000 and £70,000, half ordinary and half preference, and £20,000 of debentures. Mr. Wemyss will retain the ordinary shares, but he intends to give the public in Scoonie and Wemyss parishes the first opportunity of taking up the preference and debenture shares. It is understood that work will be actually started by the end of the month.

**Calcutta.**—*Indian Engineering* understands that the Calcutta Tramways Company have obtained the concession for carrying a line through Cossipore northwards to Barnagore. There were several projectors in the field for this scheme, but the municipalities concerned very wisely decided to accept the terms offered by the tramways company, and in due course this very important service will bring the busy riverside areas to the north of Calcutta into close touch with the city itself. The road communications in the northern section of Calcutta are not satisfactory, there being only two wide thoroughfares—viz., Cornwallis-street and Upper Circular-road—which are both far away from the riverside, where traffic is heavy and where the want of broad roads is sorely felt by those having now to drive through narrow and crowded streets in order to get to the northern suburbs.

**East Ham.**—At the meeting of the Electric Lighting and Tramways Committee the receipt of a letter was reported from the Barking Town Council, covering the conditions upon which they were prepared to allow the East Ham authority to work the length of light railway in their district from the eastern boundary in Barking-road to a point in East-street (opposite Ripple-road), Barking, and, having considered the report of the engineer and manager, the committee recommended, subject to the following terms being agreed to by the Barking Council, that the same be approved: that the charge for current consumed be the same as that charged by the Council for its own tramways; that the payment to the Barking Council per car mileage above the minimum of 83 000 car miles per annum be at the rate of 2½d. per car mile; and that the agreement be for seven years instead of three years. The recommendation was adopted.

**Manchester.**—The Tramways Committee estimate that the income for the current year from traffic revenue will be £645 250, and from miscellaneous revenue (including Salford's user of lines, rents, etc.), £4,552, making a total of £649,802, against £638,755 for the year just ended. The latter figures are rather less than the amount that was estimated—£640,665. After meeting expenditure this year a balance, it is expected, will remain of £206,122, of which £49,560 will go for interest on loans, £38 795 for sinking fund and instalment of loans, £53,200 for the renewals fund and permanent way, and £14 525 for depreciation, leaving a surplus available for the city fund of £46,000 and £4,042 in respect of the infirmary purchase. Last year the committee gave £51 000 to the city fund—£46,000 coming out of profits and £5,000 from the contingent reserve fund. The parcels department has been left out of the account, because the committee have as yet no data to go upon. On capital account the committee purpose spending £52 500 this year. Of this sum £35,000 will be for cars and car equipments. In the year just ended the expenditure on capital account was £89 277, although the estimate was £124,000.

**Rhondda Tramways Bill.**—The Select Committee of the House of Commons presided over by Sir L. M'Iver accorded part of the Urban District Council's application for extension of time. The Bill sought to prolong the time for the purchase of land and construction of waterworks, tramways, street widenings, and other works by the Rhondda Urban District Council. The only objection to the Bill had relation to the tramways clauses on the part of a few owners of property in the district. The only means of communication at the present time is that provided by the Taff Vale Railway Company. Mr. Nicholas, clerk of the Urban District Council, explained the difficulties that had arisen in connection with the construction of the tramways already authorised, and said that an extension of time for three years was required in order to purchase land for their requirements. The population of the district proposed to be served is 155,000. In the end the committee granted an extension of one year for the compulsory acquisition of land in connection with the trams, but refused the three years' extension for the construction of the tramways themselves, as the committee considered that the time available was sufficient.

**Aberavon.**—At the meeting of the Highways Committee a report was read from Colonel Druitt, who held an enquiry on behalf of the Local Government Board into the Aberavon tramways scheme. Colonel Druitt sums up as follows: "Having examined the route of the proposed tramway, I consider it very desirable that the Great Western Railway bridge should be widened, and it is to be hoped that the company will give their consent thereto; but even if the consent is not given, I do not consider the order should be refused on that account, nor if the road in Water-street cannot be widened as approved by the Council. But in any case, if the order is granted, a clause should be inserted limiting the width of cars to 6ft., the width proposed by Mr. Seldon in his evidence for the promoters. On the questions referred to me on my appointment I find (1) that two-thirds of the length of the proposed tramways are to be laid in a district the local and road authority of which consents thereto; and (2) that the consent of the Glamorganshire County Council ought to be dispensed with and the provisional order made subject to my foregoing recommendations and to such conditions as the Board may deem advisable." It was resolved to write to the Great Western Railway pointing out the desirability of widening their bridge in Water-street.

**Ashton.**—At the monthly meeting of the Town Council the Tramways Committee reported that on March 28 the surveyor submitted an estimate of the cost of constructing the proposed siding into the L. and N. W. Railway Company's yard for coal haulage, and the manager gave details showing the approximate financial result. The committee decided before proceeding further in the matter, to write to the L. and N. W. Railway Company asking if they were prepared to bear the cost of constructing the siding into their yard, as the same would always remain on their premises and form part of their property. The L. and N. W. Railway Company replied that the company could not bear the cost of constructing a siding into their premises for the use of the Tramways Department, and the manager was instructed to write asking for a full reply to the sub-committee's communication as to what arrangements they were prepared to make in respect to siding accommodation for coal haulage by electric cars. The Works and Management Sub-Committee passed the following resolution: "That the electrical engineer and tramways manager forthwith prepare a specification, and that tenders be obtained for six single-deck cars to carry from 26 to 30 passengers, similar in general design to those used by the Oldham, Ashton, and Hyde Tramways Company, and equipped with regenerative control, and alternately with series-parallel control." The minutes were confirmed. The overhead equipment of the Scotland-street section has been completed, and the route is ready for inspection.

**London County Council.**—The proposals for coming to an early arrangement with the North Metropolitan Tramways Company were again postponed on Tuesday, as the Finance Committee had not had sufficient time to investigate same. Probably a decision will be come to at the first meeting after the Easter recess. The agenda at Tuesday's meeting also contained proposals relative to the construction of new routes and the reconstruction of existing ones, to the number of nine in all, which have already been authorised. The Highways Committee recommend the conduit system, so as to facilitate connection with other lines in South London. The agreement with the Middlesex County Council, referred to in our last week's issue, in reference to the line at Highgate, was submitted for confirmation, with an estimate of £5,513 for overhead equipment, etc. Estimates of £14 747, £1 500, and £1 407 for machinery and electric light wiring at the Greenwich generating station were also submitted. The Lambeth Borough Council have decided to withdraw their opposition to the London Southern Company's project for electrifying their No wood system. The company are prepared to undertake certain street works, whilst the County Council asked the Borough Council to contribute £40,000, subsequently reduced to £25 000, when the former authority made suggestions last year for the purchase of the company's property. A further resolution was passed, by a majority of one, that if the County Council and the company came to terms for the purchase

Digitized by Google

of the latter's system the Borough Council would, having regard to the need of the improvement, make the reduced contribution of £25 000 towards the cost of street widenings. The County Council's tramway receipts for the week ended 8 h inst. amounted to £13 405, against £11,770 last year, the respective totals for the period from April 1 being £15,943 and £13,620.

**Weymouth.**—At a meeting of the Corporation the Electric Light Committee reported as follows upon the proposed electric tramways: "In accordance with the resolution of the Council passed on April 14, this committee obtained a report from Dr. Kennedy on the cost of construction and the possible results obtainable from the working of an electric tramway in this borough and district, a copy of which had been sent each member of the Council. In addition to Dr. Kennedy's report this committee has considered various alternative schemes—namely, (*a*) electric accumulator cars; (*b*) the trackless trolley system. The question of petrol cars has not been considered, but from enquiry the committee has discovered that only one municipality (Eastbourne) has obtained powers for them, the borrowing being for a very limited period. With regard to electric accumulator cars, this committee has heard that these cars have been tried in various places, but have all been discarded in favour of tramways on account of expense and technical trouble. The trackless trolley cars have been started in various places on the Continent, but unless the roads have been very carefully made and kept in first-rate order the result is utter failure. The principal Continental firm specialising in this matter has informed the committee, through Dr. Kennedy, that they have given up its further construction. The above reports being so very unfavourable, this committee feel that they cannot even submit them to the Council for consideration. Prof. Kennedy's report deals with tramways on the overhead trolley system. This committee has also considered the conduit system, as used in South London and also in parts of Bournemouth, and are of opinion that the excessive cost necessary for the construction of a line of this type makes it absolutely impossible for a return to be obtained on the capital invested. The committee had also considered the surface contact system as used in Wolverhampton, and cannot recommend it on account of the cost of construction and of the danger of 'live' studs being left in the roadway after the passage of the cars. In conclusion, this committee considers that an electric tramway service for Weymouth and the locality will at some time be a necessity, and are also of opinion that such service can be best obtained by an Act of Parliament, and they approve the system as outlined in Prof. Kennedy's report, but consider the Corporation should decide whether or not an Act of Parliament shall be promoted this session." It was decided to refer the whole matter to the Council in committee.

## LIGHTING AND GENERAL.

**Hackney.**—The Electric Lighting Committee propose to extend the electric lighting mains at a cost of £460.

**Apprentices.**—Particulars of an enquiry *re* apprenticing a lad to electrical engineering appear in another column.

**Isle of Man Telephone.**—An attempt is to be made to obtain telephonic communication between the Isle of Man and England.

**Wolverhampton.**—The Electrical Committee are about to extend the mains along Waterloo-road to Stafford-road at a cost of £950.

**Stirling.**—The Scottish Central Electric Power Company have issued the statutory notice of intention to lay electric mains in the district.

**Sunderland.**—An enquiry has been held into the application of the Corporation for sanction to borrow £15,000 for electric lighting purposes.

**Barking.**—During the past year 630,000 units were generated as against 487 000 for the previous 12 months, representing an increase of 30 per cent.

**Sale of Plant.**—Particulars of sale of second-hand electric generating sets by Kynoch Limited, Witton, Birmingham, appear in another column.

**Newbury.**—The Newbury Urban Electric Light and Power Company are holding an exhibition in the corn exchange in aid of the Newbury District Hospital.

**Clonmel Asylum.**—The Committee of Management have confirmed a previous resolution in favour of lighting the institution by electricity at an estimated cost of £2,925.

**Southend-on-Sea.**—The Corporation's returns just published show a great demand for electric lighting, the consumption in three years having increased from 200,000 units a year to 800,000.

**Reed's Electrical Co.**—The Reed's Electrical Company, of London, have opened a branch for the North of England at 24, Charles-street, Bradford, under the management of Mr. Chas. Pullan.

**Reading.**—Preparations are being made at the electrical exhibition buildings in Vastern-road, Reading, in anticipation of the formal opening of Reading's first electrical exhibition by the Mayor on Easter Monday.

**Mirfield.**—Electric light consumers are growing apace. The wiring of Christ Church, Battyeford, has been completed, and the Council have decided to extend the main from the bottom of Kitson-hill to the church.

**Ossett.**—The report and plans for an electric lighting station prepared by the engineer (Mr. W. Emmott) have been approved, and application will be made for power to borrow £8,400 for carrying out the necessary work.

**Middlesbrough.**—The Middlesbrough Chamber of Commerce have decided to ask the Telephone Company to reopen negotiations with the Corporation with a view to placing all the telephone wires in the borough underground.

**Loughborough.**—An electrical exhibition is being held at the town hall, the arrangements for which have been made and very successfully carried out under the supervision of Mr. W. H. Allen, the borough electrical engineer.

**New Issue.**—The Indian Electric Supply and Traction Company, Limited, are issuing 120,000 shares of £5 each at par, and £135,000 6 per cent. construction debenture stock at par. The company has been formed to establish and work electrical enterprises in India.

**Gravesend.**—An enquiry was held on Friday into the application of the Gravesend Corporation for an extension of their electricity area. The Hon. T. H. W. Pelham, after hearing evidence for and against, said he would consider the application and objections, and report later.

**Parliamentary Bills.**—The Chelsea Electricity Supply and the Walton-on-Thames Electricity Supply Bills were read a second time in the House of Lords on Friday. The West Cumberland Electric Tramways (Extension of Time) Bill was read a second time in the House of Commons on Monday.

**Islington.**—The Borough Council have decided to instal six mechanical stokers at the electric lighting works at a cost of £300 each. Overhead steel bunkers, a coal elevator and conveyor, and motors and accessories, with labour and other work, will, as anticipated in our last issue, bring the cost up to £4,500.

**Heywood.**—The Electricity and Tramways Committee in their last report state that the consumption of electricity for February, 1905, was 7,273 units, as against 6 121 units for the corresponding period of last year, showing an increase of 1,152 units. Tenders are to be obtained for the supply of 600 tons of washed slack coal for the ensuing 12 months.

**Hanley.**—The Town Council have received from the Electric Lighting Committee £1,150 to the credit of the district fund account. The price for electrical energy for private lighting is to be reduced from 6d. for the first 150 hours' use per quarter of the maximum demand supply and 3d. for all further consumption, to 6d. for the first 91 hours' use (or one hour per day) and 3d. for all further consumption.

**Electrical Plant (U.S.A.).**—The directors of the Allis-Chalmers Company, of Milwaukee, have decided to make an immediate expenditure of three million dollars on the extension of their works for the purpose of manufacturing electrical machinery of the largest type as well as steam and hydraulic turbines and gas-engines. The electrical department at Milwaukee will be operated in connection with the big plant of the Bullock Electric Company at Cincinnati, which is owned by the Allis-Chalmers Company.

**New Company.**—The Adelaide Electric Supply Company, Limited, has been registered with a capital of £300,000 in £5 shares, the object being to carry on in Australasia and elsewhere the business of electrical and general engineers, electricians, contractors, carriers of passengers and goods, manufacturers of and dealers in railway, tramway, electric, magnetic, galvanic, and other apparatus generators, etc. The first directors are J. B. Braithwaite, A. F. Parish, and R. P. Sellon, Mansion House-buildings, E.C.

**Belfast.**—Current will be supplied to the Cavehill and Whiterell Tramway Company on the following conditions under a 12 months' notice: the supply to be taken from and metered at the Fortwilliam sub-station; the company to bring their cables into the sub-station; the maximum demand to be 120 kw.; the minimum quantity to be paid for per annum to be 150 000 units; and the price to be for the first 150,000 units per annum, 2d. per unit; for the next 25,000 units per annum, 1¾d. per unit; and for the next 25,000 units per annum, 1½d. per unit.

**Paddington.**—The Borough Council on Tuesday discussed an agreement with the Metropolitan Electric Supply Company consenting to the removal of the Amberley-road generating station and the entire supply of the borough from the company's works at Willesden. The company offered, under five years' agreements with consumers, to make reductions in the price of current as follows: private house lighting, from 5½d. to 5d. per unit for the first two years, and 4¾d. in the remaining three years; trade lighting (including churches and schools) from 6d. to 4¾d. per unit the first two years, and 4½d. afterwards. An amendment in favour of taking expert and legal advice before the Council committed itself was adopted.

**London County Council.**—On Tuesday it was agreed that, with a view to relieving telephone users in the London area, the maximum rate fixed by the agreement of 1901 between the Postmaster-General and the National Telephone Company should be reduced; that Clause 4 (1) of the new agreement be amended so as to make it clear that no addition shall be made to the value of items, other than "plant" of the company's undertaking, in respect of compulsory purchase and that the Parliamentary Committee be authorised to endeavour to obtain such further modification of the proposed terms of purchase in the interests of the telephone users of London as may be desirable. The Council have sanctioned the borrowing of £8 500 for the installation of the electric light within the borough of Woolwich, to be repaid within 42 years.

**Institution Journal.**—Part 171, edited by G. C. Lloyd, secretary (E. and F. N. Spon, Limited), contains "The Combination of Dust Destructors and Electricity Works Economically Considered" (with discussion) by W. P. Adams; "Fuel Economy in Steam-Power Plants" (with discussion), by W. H. Booth and J. B. C. Kershaw; "Compensated Alternate-Current Generators" (Manchester Local Section), by Miles Walker, B.A. (with discussion); "High-Tension Switchgear" (Manchester Local Section), by L. Andrews (with discussion); "Armature Reaction in Alternators" (Glasgow Local Section), by J. B. Henderson, D.Sc., and J. S. Nicholson, B.Sc. (with discussion); "Condensing Arrangements in Central Stations" (Leeds Local Section), by J. D. Bailie; "The Magnetic Properties of some Alloys of Iron and Silicon," by T. Baker, M.Sc.

Digitized by Google

**Stock Exchange.**—The Stock Exchange Committee have ordered the British Electric Traction Company's further issue of 5,000 6 per cent. cumulative preference shares of £10 each, fully paid, Nos. 356,438 to 361,437, to be quoted in the official list.

**Truro.**—The Electric Power and Light Committee are conferring with Mr. J. A. Purver, of Exeter, and the surveyor has been instructed to make enquiries as to what municipalities of a size similar to Truro had undertaken their own electric lighting.

**Harwich.**—The Board of Trade have given notice that they have revoked the Harwich (Corporation) Electric Lighting Order, 1892, as confirmed by the Electric Lighting Orders Confirmation (No. 2) Act, 1892, as to the whole of the area of supply, as from March 31, 1905.

**African Telegraphs.**—Mr. Merlaux Ponty, Governor of Upper Senegal, is at Paris in connection with his scheme for a new telegraph line to cross the Sahara from Algiers to Timbuctoo, and ultimately to Lake Chad. This line is estimated to cost £240,000. The route has been surveyed.

**South Wales Electrical Power Bill.**—The South Wales Electrical Power Distribution Company's Bill has passed the committee stage, and will in due course be reported for third reading. The object of the Bill is to transfer and vest in the South Wales Electrical Power Distribution Company the undertaking of the Carmarthenshire Electric Power Company and other purposes.

**Southampton.**—An enquiry has been held into an application of the Borough Council for sanction to borrow £6,950 for purposes of electric lighting made up as follows: £6,300 for excess expenditure from the previous loan for the erection and fitting of the new works; £520 for extension of mains in Oxford-street, Bernard-street, and Bridge-street; and £130 for two 10-ton coal trucks.

**Weymouth.**—A resolution recently passed by the ratepayers' association asking whether they would grant permission for any ratepayers desirous of so doing to visit the electric light works and destructor, and to name a date for such visit if granted, has been handed on to the Electric Lighting Committee with a recommendation that the members of the ratepayers' association should be allowed to view the works.

**Brighton.**—The *West Sussex Gazette* says it was arranged with the Shoreham Harbour Trustees that the Brighton Corporation should dredge down 6ft. across the canal at Southwick before laying the electric cables from the great power station there. Hard strata have been met with to prevent dredging to the full depth. Having regard to the safety of the harbour and the vessels using it, the trustees say they cannot consent to the cables being laid at a less depth.

**Warrington.**—The engineer estimates the cost of providing new condensing plant at £1,200, and the Town Council intend to apply for sanction to the borrowing of the said sum, and also, in addition to the following, £1,000 for land; £100 for shed, partition, and palings; £1,000 for four mechanical stokers and pipework; £500 for water softener; £100 for foundations, motors, and accessories; £200 for lathe, drilling machine, and accessories; and £50 for contingencies.

**New Photo-Copying Process.**—We have received from the "Blue Print" Company, of 128-30, Edmund-street, Birmingham, some samples of photo-copying done by a new process which they have protected. The feature of the process is that it reproduces in black lines on drawing-paper or on linen, and that there is no shrinkage in the copy so made. The examples sent to us are excellent, the lines being sharp and clear. The details of the process are not to hand, but information as to the same can be obtained from the firm.

**Lichfield.**—The promoters of the Shropshire and Worcestershire Electric Power Bill having agreed to insert in the Bill the clause agreed to by the Council as to the supply of energy within the city, and also an amendment incorporating therein the provisions of the promoters' Act of 1903 and the Acts incorporated therewith, the petition in opposition presented on behalf of the Corporation has been withdrawn. Messrs. Foote and Milne, Limited, have deposited with the Council a print of the provisional order for public inspection.

**Hammersmith.**—The Electricity and Lighting Committee require additional office and workshop accommodation. The premises of 18 additional consumers, representing a maximum of 352 8-c.p. lamps, have been connected to the mains, and 14 consumers disconnected. The present number of consumers taking current from the mains is 1,567. Seven new lamps are to be erected in Aldbourne-road and Askham-road. It is proposed to supply the National Electrical Manufacturers' Association with current at the proposed exhibition of electrical appliances to be held at Olympia from Sept. 25 to Oct. 21, 1905, on the following terms: (*a*) the Council to supply both continuous and alternating current as required up to 60,000 8-c.p. lamps at its exhibition stands at 1¾d. per unit; (*b*) a charge of 10s. 6d. to be made for connection and meter hire to each stand requiring 20 lamps or less, and 21s. for each stand of larger requirements; (*c*) if the cost of distribution of current is less than ¾d. per unit, such saving to be equally divided between the Council and the association; (*d*) a deposit of £600 to be paid to the Council by the association when the Council commences the outlay for distributing inside Olympia; (*e*) the Council to show the amount of current used by each exhibitor, but to render the accounts to the executive committee of the association, who hold themselves responsible for the whole supply.

**Govan.**—The Town Council, after considering the report by the electrical engineer with regard to the matter of charges for electric lighting to private consumers, have agreed not to take any action in the matter meantime. The engineer's report stated that during the 12 months ending Nov. 15 last the department sold for lighting 399,178 units at the following prices: 286,079 units, at maximum demand, 6d. and 1d., £3.572. 12s., showing a realised price per unit 2·951.; 36,294 units at flat rate of 4d., £604; 73 215 units at flat rate of 3½d, £1,067. 14s. 4d.; and 3,590 units at flate rate of 3d., £44. 17s. 6d. Exclusive of the accounts charged on the flate rates of 3½d. and 3d., there were 207 accounts that had run the full 12 months. These represented 288,322 units, equal to £3,813. 5s., or an average price per unit of 3·17d. He thought it fair to take these 207 accounts for a basis of comparison, and if the system of supply were changed from the maximum demand to a flat rate of 3½d. these 288,322 units would bring in £4,209. 13s. 1d. The rate would be lowered to 104 consumers, using 84,571 units, costing £1,545. 13s. 10d., and raised to 103 consumers, using 203 751 units, costing £2 297. 11s. 2d. If the maximum demand system were retained as at present, and the optional flat rate reduced to 3½d., the total revenue from the 288,322 units would be £3,530. 17s. 8d., a decrease of £282. 7s. 4d. It would be seen that the bulk of the units sold were on the maximum demand system, and that the average price was under 3d. per unit, so that to adopt a universal flat rate of 3½d. would not be to the advantage of the majority of the consumers. On the other hand, if this optional flat rate were reduced to 3½d. it was possible that for a year or so the department might suffer a little loss, but he thought the reduced charge would be an additional inducement for consumers to come on, and that they should probably gain in the long run.

**New Issue.**—The Adelaide Electric Supply Company, Limited, are issuing at par 10,000 6 per cent. cumulative preference shares of £5 each, payable as follows: 10s. per share on application, 10s. per share on allotment, £2 per share on May 15, 1905, and £2 per share on July 15, 1905—£5. This company was formed for the purpose, *inter alia*, of acquiring from the Electric Lighting and Traction Company of Australia, Limited, the business and undertakings in Adelaide and Port Adelaide now owned by that company. The properties to be acquired by the company include a freehold central station in Adelaide, supplying electricity in the city and suburbs; a small leasehold station, also in operation, at Port Adelaide; and the South Australian Electric Light and Motive Power Company's Act, 1897, granted by the Government of South Australia. About 72 miles of mains have now been laid, and the total connections at Jan. 31, 1905, were equal to 52,733 8 c.p. lamps. The advantages of electric light in the climate of Adelaide are becoming generally recognised, and the rate at which additional applications for supply are being received continues to be satisfactory: there is a growing demand also for motive power, the equivalent of 714 h.p. having been connected to the mains up to Jan. 31, 1905. Electric supply has heretofore been chiefly confined to the business area of the city of Adelaide proper, but mains are now being laid in the residential districts surrounding the city, and new consumers are being rapidly connected. The generating station at Adelaide is equipped with machinery of most recent construction, and the cost of generating electricity compares favourably with that of other modern electric supply stations in Great Britain and elsewhere. The capacity of the generating plant already installed is equivalent to 760 kw., and the existing station buildings are large enough to accommodate future extensions of plant for several years to come. A small station at Port Adelaide has been in operation for about five years, and the connections at Jan. 31, 1905, were equivalent to 6,482 8 c.p. lamps. This station has hitherto worked at a loss, the average deficit being about £250 per annum. It is proposed to supply the district from the Adelaide station, which will, it is believed, convert the present loss into profit, especially as negotiations are in progress for extending the Port Adelaide mains into districts hitherto untouched, from which there is a good prospect of revenue.

**Sudbury.**—A long discussion took place on the electric lighting question at the last meeting of the Town Council. The minutes of a meeting of the General Purposes Committee of the Council of April 10 stated that the Mayor had referred to the recent lawsuit between the Council and the Empire Electric Lighting Company. At the meeting the town clerk read the following statement: "When the Council decided (in consequence of the refusal of the Local Government Board to sanction a loan) to enter into an arrangement with a company to carry out the provisions of the order, I wrote, by the instructions of the Council, to the Board of Trade, informing them of the intention of the Council, and asking if the Board would be prepared to sanction such an arrangement. The Board replied that they did not appear to have any power to do this, which seemed to mean that the matter was not within their jurisdiction. Mr. Bartley Dennis, who conducted the Local Government Board enquiry on behalf of the Council, advised that an agreement could be legally entered into without any sanction from the Board of Trade. The agreement was prepared on behalf of the Council, and by their instructions, under Mr. Hawtayne's supervision, by his own solicitors, who were stated to possess the necessary technical knowledge, and they also had the assistance of Mr. Bartley Dennis, who has very large experience in these matters. This agreement was approved by the solicitors to the Empire Company, and the directors, and also by the Town Council, and finally sealed by both parties in duplicate. During the negotiations the Board of Trade was kept fully informed of all that was being done, and they twice extended the time of the order for the negotiations to be completed. I need not refer to the default of the company to carry out the agreement, nor the instruction to proceed against them for damages. In the action, the only defence put in by the Empire Company was that the agreement was invalid, because the sanction of the Board of Trade had not been obtained under Section 11 of the Electric Lighting Act of 1882, which is as follows: 'Any local authority who have obtained a license, order, or special Act for the supply of electricity may contract with any company for the execution and maintenance of any works needed for the purposes of such supply, or for the supply of electricity within any area mentioned in such license, order, or special Act, or in any part of such area, but no local authority, company, or persons shall, by any contract or assignment, transfer to any other company or person, or divest themselves of any legal powers given to them, or any legal liabilities imposed on them by this Act, or by any license order, or special Act, without the consent of the Board of Trade.' It will be seen from the first part of this section that a council

Digitized by Google

may contract for the carrying out of the works, which is all that this agreement was intended to do; and that, by the second part of the section, a council may, with the consent of the Board of Trade, actually transfer and get rid of all their legal liabilities and obligations and rights, which was never contemplated as intended by the agreement. I have always advised the Council that the agreement could not operate to transfer any legal liabilities to which they must always remain subject, and, in support of this view, there is the following clause in the agreement: 'Nothing herein contained shall be deemed . . . to create any relationship between the Corporation and the company which the Corporation are prohibited from transferring, or creating by the order and the Electric Lighting Acts, 1882 and 1888, and particularly by Section 11 of the Act of 1882, the intention being for the Corporation to give to the company every facility in their power for carrying out this agreement without transferring or assigning any of the powers or duties under the order.' It would seem that nothing could be clearer; but at the trial the judge held that the whole intention and effect of the agreement was to transfer the legal liabilities of the Council to the company, and that the above-mentioned clause was useless; that the agreement was consequently invalid, and there was no basis on which to form an action for damages. I cannot think this decision is good law, and I think the Council should appeal, as there is every reason to hope that the decision would ultimately be in favour of the Council." The committee recommended that a small committee be appointed to consider the question, to take counsel's opinion with the view to an appeal against the decision of the judge, and to report to the Council. The report was adopted.

**Telephone Exchange Fire.**—The coroner's enquiry into the two fires which occurred simultaneously in the premises of the National Telephone Company at Mansion House-chambers, 11, Queen Victoria-street, and 1 and 2, Oxford-court, Cannon-street, on the morning of Tuesday, Feb. 28, was concluded on Tuesday. Mr. C. B. Clay, the metropolitan superintendent of the National Telephone Company, recalled, said that no special instructions were issued to the company's exchanges as to any action to be taken during a thunderstorm, because there was no special danger, and no one had yet met with an accident during a storm since the company's existence of 23 years. Signalman Doyle, of the District Railway Company at Westminster Bridge Station, said that at 1.39 on the morning of Feb. 28 he saw a flash under the girders on the up-line, and then a bright arc appeared and burned fiercely for about 10 minutes. At two o'clock a similar thing occurred on the down line. Some of the signal wires were fused, and also a gas-pipe, the gas burning as it came out of the ground. He turned the gas off at the main. Mr. Bennett thought it would be quite safe to leave the telephone wires in the District Railway tunnels, but they should be removed entirely from proximity to the power cables, and cased in wood or earthenware or non-conducting material. It was not safe to put the telephone wires in iron troughs, because, if a fault occurred, they might become "alive," and carry the high potential of the power cable into the telephone wires. Protectors should be provided at all telephone exchanges and at all subscribers' premises. Mr. Gaine, general manager of the National Telephone Company, said if a fire occurred in a subscriber's house he had first to ring up the telephone exchange. Then the call had to be put through to Southwark, and Southwark had to send it on to another station. In every large town in Great Britain a telephone user could get straight through to the station in a few seconds. Lieut.-Colonel Fox, chief of the Salvage Corps, regarded the practice of erecting heavy derricks for supporting telephone cables over buildings most dangerous. Overhead telegraph and telephone wires constituted a grave danger to the public in case of fire. Nobody was injured at this fire, but if it had occurred in the daytime the falling cables might have killed half a dozen people. The Coroner said the duty of making this investigation was thrown upon him as City coroner because there was no jurisdiction in the present case other than that afforded by the City of London Fire Inquests Act, 1888. The Board of Trade had no power to order an enquiry. Being of comparatively modern introduction, telephone systems appeared to have hitherto remained outside any official control. It was for the jury to decide whether the evidence laid before them in the present enquiry revealed such a state of affairs as to render Government enquiry and action desirable in the interest of the community at large. The jury submitted the following answers to his questions: (1) When and where did the fire of Feb. 23 last originate in the National Telephone Company's premises at Mansion House-buildings and Oxford-court? We find that the fire occurred at about two o'clock on the morning of Feb. 28 in both cases, and in what are known as the test-rooms of the National Telephone Company. (2) The cause of the fire in each case? Caused by a powerful current of electricity transmitted through the cables of the National Telephone Company to the test-room at the Bank exchange, and from there to the test-room at Oxford-court. The above current was derived from a charged conductor rail of the District Railway Company through the contact or arcing between the cables of the National Telephone Company at Westminster Bridge Station and such conductor rail. (3) Was the cause due to accident or negligence? There is not sufficient evidence to show. (4) Should telephone cables or wires be laid near high-tension currents? Not unless effectually protected. (5) Is the contact of a telephone wire with a high-tension current likely to be dangerous on account of fire in the subscribers' houses and shock or fatal injury to operators or subscribers? We say "No," when properly protected in both cases. (6) Do you consider the National Telephone Company's testing and distributing rooms were reasonably constructed to resist fire? We consider the construction of the test and distributing rooms leaves great room for improvement, and would suggest a greater use of non-combustible material and the use of modern safety devices in all exchanges. (7) Are special powers required to regulate all structural and other matters connected with the telephone service? Yes. (8) Is a Government enquiry needed into the telephone risks and needs? We see no necessity. (9) Do you consider the Oxford-court premises satisfactorily provided with means of escape in case of fire? No, we do not.

## PROVISIONAL PATENTS, 1905.

APRIL 6.

**7277. An improved case and cover for fire alarms, electric bell calls, and the like.** Joseph Henry Golding, Amhurst Electric Works, Garnham-street, Stoke Newington.

**7295. Improvements in or relating to alternating-current electric motors.** Benjamin Garver Lamme, The Westinghouse Patent Bureau, Westinghouse Building, Norfolk-street, Strand, London. (Date applied for under Patents Act, 1901, May 3, 1904, being date of application in United States.) (Complete specification.)

**7304. Improvements in electrically-operated burglar and like alarms.** Thomas William Senior and James George Farquhar, 55, Chancery-lane, London.

APRIL 7.

**7350. Electro-mechanical tenter hook detector.** Wilfrid Hemingway, Arthur Silcock, and Clifford Broughton Hogg, 100, Meadow-lane, Leeds.

**7359. A device for automatically regulating the resistance on a switchboard for electrical-driven machine or lights in conjunction with the governor of the engine.** John Lamb and Orlando Thomas Newton, 56, Strand-road, Bootle, Liverpool.

**7360. An improved device for keeping the trolley rope of a electric car tight, when the boom is in various positions.** James Lawson Dawson, John Clark, and Robert Blackmore, Victoria House, Manchester-road, Mossley.

**7405. Improvements in contact devices for electric switches.** The Elektrizitäts Actien-Gesellschaft vorm. W. Lahmeyer und Co., 47, Lincoln's-inn-fields, London. (Date applied for under Patent Act, 1901, May 9, 1904, being date of application in Germany.) (Complete specification.)

**7416. Improvements in vapour electric apparatus.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (General Electric Company, United States.)

**7417. Improvements in signals for railways and the like.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (General Electric Company, United States.)

**7418. Improvements in relays for electric circuits.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (General Electric Company, United States.)

**7419. Improvements in and relating to signalling systems.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (General Electric Company, United States.)

**7420. Improvements in electric systems for controlling guns and the like.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (General Electric Company, United States.)

**7421. Improvements in and relating to electrically-driven vehicles.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (General Electric Company, United States.)

**7422. Improvements in signals and mechanism therefor.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (General Electric Company, United States.)

APRIL 8.

**7436. Improvements in automatic motive power by electricity.** William Norman Lascelles Davidson, 20, Middle-street, Brighton.

**7438. Improved method of securing the removable cover of a tumbler or like electrical switch.** Edward Thomas Davies, 11, Burlington chambers, New-street, Birmingham. (Complete specification.)

**7443. Apparatus for recording the time in which a current has been flowing in an electrical circuit.** Kelvin and James White, Limited, and Joseph Menmuir, 154, St. Vincent-street, Glasgow.

**7444. Improvements in or connected with electric lamps, particularly applicable to the tail lamps of motor vehicles.** James William Greenwood, Palatine-chambers, Market-street, Halifax.

APRIL 10.

**7534. Improvements in and relating to heating by electricity.** Frank Wynne, Lightwater House, Bagshot.

**7591. Improvements in connection with alternating-current machines for synchronising and connecting them with distributing conductors.** James Yate Johnson, 47, Lincoln's-inn-fields, London. (Voigt und Haeffner Akt.-Ges., Germany.) (Complete specification.)

**7595. Improvements in means or apparatus suitable for indicating leakage of electricity.** James Frederick Driver, 46, Lincoln's-inn-fields, London.

**7596. Improvements in or relating to apparatus for supplying alternating electric currents.** Arthur Francis Berry, 46, Lincoln's-inn-fields, London.

Digitized by Google

**7605. Improvements in collecting devices for dynamo-electric machines.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (General Electric Company, United States.)

**7606. Improvements in and relating to electromagnetic switches.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (General Electric Company, United States.)

**7617. Improvements in electric cut-out switches.** Joseph Frechette, 18, Buckingham-street, Strand, London. (Complete specification.)

**7626. Apparatus for the measurement of X-rays and other similar radiations.** Georges Eugène Gaiffe, 53, Chancery-lane, London.

## COMPLETE SPECIFICATIONS ACCEPTED.

*To be published April 27.*

1904.

**13223. Electrolytic meters.** Holden, and Chamberlain and Hookham, Limited.

**13952. Apparatus operating with automatic regulation for submitting gases and vapours to the action of the electric arc.** Imray. (Soc. Anon. d'Etudes Electro-Chimiques.)

**16301. Self-restoring inter-communication telephone.** Freeman and Pearce.

**20846. Electric circuit breakers or switches.** Liddle. (Hartman.)

**21642. Electrical apparatus for adjusting tramrail points from the car.** Macaulay.

**25639. Space telegraphy.** Stone. (Date applied for under International Convention, Nov. 24, 1903.)

**25898. Switchboards for telegraphic, telephonic, and other electrical systems.** Mills. (Hammond.)

**26679. Electric circuit protecting devices.** Schäffer. (Date applied for under International Convention, Dec. 9, 1903.)

**27135. Hangers or ears for overhead electric trolley wires.** Heap, Bailey, Brierley, Billington, Richardson, Haydock, and Jones.

**27637. Vapour electric apparatus.** Dempster. (Date applied for under International Convention, Dec. 19, 1903.)

**28455. Central telephone station installations.** Siemens Bros and Co., Limited. (Siemens und Halske Akt.-Ges.)

**28601. Apparatus for electro-deposition of metals.** King.

*To be published May 4.*

1904.

**8323. Telephonic repeating system.** Downing. (Gally.)

**8403. Alternating electric current motors and generators.** The British Thomson-Houston Company, Limited. (General Electric Company.)

**8501. Controllers for the motors of electrically-propelled vehicles.** Cummins.

**8620. Electric motors.** Von Zweigbergk.

**10502. Prepayment electricity meters.** Griesbach.

**10880. Transmitting power electrically and controlling same.** The British Thomson-Houston Company, Limited. (General Electric Company.)

**10882. Electric meters.** The British Thomson-Houston Company, Limited, and Holden.

**11704. Railway or tramway signalling systems.** The British Thomson-Houston Company, Limited. (General Electric Company.)

**11880. Magneto electric generators.** Albion Motorcar Company, Limited, and Murray.

**12337. Thermal cut-outs for electric circuits.** The British Thomson-Houston Company, Limited. (General Electric Company.)

**12338. Electric switches.** The British Thomson-Houston Company, Limited. (General Electric Company.)

**13158. Plastic composition suitable for the manufacture of buttons, electrical insulating material, or other articles, and process of manufacturing same.** Geipel.

**13161. Manufacture of filaments for incandescent lamps.** Carolan. (General Electric Company.)

## NOTES.

**New Publications.**—"The Telegraphists' Guide," by Jas. Bell and S. Wilson. (London: S. Rentell and Co. 2s.) The authors have compiled a treatise designed to meet the requirements of the Government telegraph service in regard to higher appointments. Students preparing for the examinations in telegraphy of the City and Guilds of London Institute, and of the Science and Art Department, will also find the book serviceable.

**International Fire Service Council.**—The International Fire Service Council, which was founded in 1900, and represents the interests of the world's various fire brigade and fire preventive societies, held its annual executive meeting at Brussels on the 17th and 18th inst. Matters relating to fire-alarms were discussed at length, and a standing committee, comprising, among others, Chief Officer Meier (late of the Dutch Royal Engineers) and Chief Officer Reichel (of the Royal Technical College, Hanover), both authorities on the subject, has been formed. The council's enquiry office at Luxemburg is now open, and technical questions can be addressed there through any of the three British societies represented on the council. Mr. Edwin O. Sachs represented the British Fire-Prevention Society at the conference.

**Royal Meteorological Society.**—At the monthly meeting of this society Dr. H. R. Mill read a paper on the "Rate of Fall of Rain at Seathwaite." This was a consideration of the records from a Negretti and Zambra self-recording rain-gauge during a period of 18 months. Seathwaite, which is in Borrowdale, Cumberland, is in almost the wettest spot of the British Isles, the average yearly rainfall being about 137in. Dr. Mill's results seem to show that the rainfall at Seathwaite in an average year indicates a tendency to be greater during the hours of darkness than in daylight, that rather less than half the time during which rain is falling it continues without intermission for at least six hours at a time, and that rather more than half the total amount of rain is deposited in these long showers.

**Society of Arts.**—Two illustrated lectures on "The Uses of Electricity in Mines" are to be delivered before this society by Mr. H. W. Ravenshaw, the dates being May 15 and 22. The first lecture will deal with the following subjects: application of electricity and character of load; winding; hauling; pumping; coal-cutting; other uses underground; surface requirements; generating stations; cables and distribution; lighting; signals; telephones; shot-firing. The second lecture will deal with different kinds of currents; precautions; enclosed motors; Home Office rules and cost, while typical and historical plants will be described. These lectures, which will no doubt prove both instructive and interesting, come at an opportune time, having regard to the regulations on this subject recently promulgated by the Home Office. We notice that the society's conversazione will again be held at the Royal Botanic Gardens, Regent's Park, on Tuesday, July 4, from 9 to 12 p.m. The programme will be announced in due course.

**Electric Lighting in New York.**—The legislative investigation into the cost of gas and electric light in New York is proceeding, and the technical evidence is of general interest as showing the cost of electricity in that city. From the evidence which has appeared in our American contemporaries we gather that 7½d. per unit is the rate charged for the first two hours. For the next two hours the rate falls to 3¾d., and further consumption is at the rate of 2½d. per unit. It was shown that only 34 per cent. of the current is sold below 7½d. per unit. The average income per unit works out at 6·13d. Public lighting is provided at 6d. per unit with certain exceptions. These exceptions are made when a considerable amount of power is used in addition to the lighting. The evidence given as to the cost of generation and supply is also of interest. These figures show that the average cost per unit sold at Manhattan and Bronx was 1·83d. The total cost was 3·16d., and the average total cost for the last five years 3·99d. Taking the power consumption in with the lighting, the average income for the last year for energy supplied by these companies was 4·02d., and for the last five years 4·05d. We gather that the New York companies are paying good dividends, but that they are at the same time reducing the cost of electrical energy to their customers.

**Incorporated Municipal Electrical Association.** The tenth annual convention of this organisation will be opened at Edinburgh on June 27. In the morning the presidential address will be delivered, after which there will be reading and discussion of papers. A visit will be paid to the electricity works in the afternoon, and in the evening there will be a reception by the Lord Provost. The party will proceed to Glasgow, and on the following day, June 28, the morning will be devoted to the reading and discussion of papers, the electricity and other works being visited in the afternoon. Returning to Edinburgh, more papers will be read and discussed on the morning of the 29th, and in the evening the annual dinner will take place. The conference will terminate with the annual general business meeting on the morning of the 30th. The subjects to be discussed include "Load Factor—its effect upon an Electricity Station," "Street Lighting," "Extensions to Outlying Areas," "Free Wiring and Supply on the Prepayment System," "Allocation of Costs," and "The Supply of Electricity in Industrial Areas, from a Municipal Point of View." A detailed official programme will be issued in due course, and in the meantime all communications should be addressed to Mr. C. McArthur Butler, Staple Inn-buildings, Holborn, W.C. The North British Railway Hotel, Princes-street, Edinburgh, has been selected as the headquarters.

**Electrical Distribution in the States.**—The *Electrical World* gives an interesting abstract of a report by the Massachusetts Board of Gas and Electric Light Commissioners for the year 1904. It seems from this that there were in that State 21 municipal electric light stations and 82 owned by companies. The proportion of municipal undertakings is thus very much lower than in this country. Of the 21 above mentioned three were only distributors, and bought their supply of electricity in bulk. Of the 82 companies 56 operated electric light stations only, the others being interested in other commercial undertakings as well. Of these 56 central stations one did not earn enough to meet expenses, and 26 others did not declare any dividend. The other 29 paid dividends ranging from 2 to 10 per cent. The financial results with the municipal central stations were even less satisfactory. Thus during the year the income of all the stations amounted to £47,368, and the expenditure to £64,379, leaving an apparent loss of £17,011. This, however, was without including interest on loans and depreciation, which would make the deficit almost 200 per cent. more. We gather from the report that the use of arc lighting is on the decrease in the districts in question, but that the increase in incandescent lamps more than makes up for any falling off in this respect. It also appears from the report that municipal lighting is not spreading in Massachusetts.

**Platinum Resources of the United States.**—The United States Geological Survey has decided to make an examination of the platinum resources of the Republic, the

Digitized by Google

demand for this metal having greatly increased. It is proposed to collect the heavy sands from all placer mines in the United States where evidence of platinum has been found by preliminary tests. The samples thus obtained will be used in determining the best methods of extracting the various minerals which have economic value. It is considered that the separation and sale of useful minerals, such as magnetite, chromite, garnet, monazite, rutile, topaz, zircon, gold, platinum, iridosmine, etc., may become a permanent and profitable industry. As a preliminary step in this investigation, owners of placer deposits have been invited to transmit likely samples of their placer deposits to the Geological Survey. This material will be carefully examined, and the owners duly notified of the results. After an examination of these preliminary samples, experts will be sent to all localities where the tests give promise of platinum in profitable quantity. The expert will report on the size of the deposit and superintend the collection of representative samples for concentration. Concentration experiments will probably be carried out in connection with the exhibits of mining machinery at the Lewis and Clark Centennial at Portland, Ore, between June 1 and Oct. 15 of this year. Platinum has been discovered in California, Oregon, Idaho, Montana, New York, North Carolina, Georgia, Pennsylvania, Wyoming, and Alaska, in the United States, and in Canada, Mexico, Central America, the West Indies, and South America.

**The Institution of Civil Engineers.**—At the annual meeting of the Institution of Civil Engineers, held last week, Sir Guilford Molesworth, K.C.I.E, president, in the chair, the result of the ballot for the election of officers was declared as follows: president—Sir Alexander Binnie; vice-presidents—Dr. Alexander B. W. Kennedy, Mr. W. R. Galbraith, Mr. William Matthews, C.M.G., and Sir Leader Williams; other members of council — Colonel W. P. Anderson (Ottawa, Canada), Mr. C. Napier Bell, (Wellington, New Zealand), Mr. B. Hall Blyth, M.A. (Edinburgh), Mr. C. A. Brereton, Mr. R. Elliott-Cooper, Colonel R. E. B. Crompton, C.B., Mr. W. J. Cudworth (York), Dr. G. F. Deacon, Dr. F. Elgar, Mr. Maurice Fitzmaurice, C.M.G., Mr. R. A. Hadfield (Sheffield), Mr. G. H. Hill, Mr. C. W. Hodson, C.S.I., Mr. J. C. Inglis, Mr. G. R. Jebb, Sir William Thomas Lewis, Bart. (Aberdare), Mr. A. G. Lyster (Liverpool), Sir Charles Metcalfe, Bart. (Cape Town), Sir Andrew Noble, Bart., K.C.B. (Newcastle-on-Tyne), the Hon. Charles A. Parsons, C.B. (Wylam-on-Tyne), Mr. A Ross, Mr. A. Siemens, Mr. John Strain (Glasgow), Sir John I. Thornycroft, Prof. W. C. Unwin, B.Sc., and Mr. A. F. Yarrow. The council have made the following awards for papers read and discussed before the institution during the past session: Telford gold medals to Lord Brassey, K.C.B., and Mr. C. S. R. Palmer; a George Stephenson gold medal to Mr. Lyonel E. Clark; a Watt gold medal to Mr. J. F. C. Snell; Telford premiums to Messrs. L. F. Vernon-Harcourt, M.A., R. W. Allen, and Wm. Marriott; a Crampton prize to Mr. A. Wood-Hill, and the Manby premium to Mr. E. D. Pain. The presentation of these awards, together with those for papers which have not been subject to discussion, and will be announced later, will take place at the inaugural meeting of next session.

**Car Obstruction**—We have instanced several cases from time to time in which trams have been obstructed more or less deliberately, but for sheer wilfulness it would be difficult to surpass the conduct of a baker's assistant who, as reported in our last week's issue, was summoned at the Spelthorne Petty Sessions. The defendant's conception of the law appears to have been that it was quite permissible for him to delay any vehicle, provided he limited this form of pastime to 20 minutes. Our senators have accomplished some remarkable legislative feats at various times, but, notwithstanding Sam Weller's historic declaration, we do not remember to have heard that the Statute Book contains any such asinine provision as would countenance deliberate obstruction. It appeared that the defendant habitually indulged in the practice of placing his van, while he was unloading goods, so that the wheels on one side projected over the tramline. On one occasion when an onlooker pulled the van off the rails after it had obstructed a car for eight minutes, the defendant deliberately replaced it on the line and further delayed the car. Several witnesses testified to the fact that there was an ample margin between the kerb and the tramlines. The accused's advocate endeavoured to draw a herring across the path by pleading that the company had agreed with the Teddington Urban District Council to widen the road and had failed to do so, but this side issue was promptly ruled out as irrelevant. After hearing all the evidence the Bench unanimously came to the conclusion that the defendant was acting with intent to cause annoyance, and inflicted fines totalling £5. At the same time it was intimated that a repetition of the offence would be visited with the maximum fine—which it would well merit—if, indeed, such conduct deserves the option of a fine.

**Electrical Activity in the Transvaal.**—The activity lately exhibited in electrical matters in the Transvaal—for which country the Colonial Secretary has just promulgated a new Constitution—is likely to receive a further stimulus from the proposals of the Johannesburg and Krugersdorp Corporations. The former authority contemplates raising a loan of 2½ millions, of which the tramway and lighting scheme is expected to absorb considerably more than half. It appears that a portion of the new lighting plant has already been installed. The Corporation expects to be in a position to change over a large proportion of the present consumers in the inner area to 230 volts, and to connect up new consumers in October. For the outer area alternating current will be supplied at a pressure of 200 volts. A limited supply will be available by about June. The Johannesburg Chamber of Trade recently considered the question of the alteration of pressure, and finally referred the matter to committee with an instruction to ask the Corporation for a reduction in cost corresponding to the increased expenditure involved by such change of pressure. The Town Council of Krugersdorp has likewise propounded an electric lighting scheme, though naturally of a much less ambitious character, the cost being estimated at £16,000. We notice from the report of Lord Milner's valedictory speech that the late High Commissioner, in vindicating the Transvaal from the charge of stagnation since the war, took occasion to congratulate engineer and electrician upon the progress made during that period in railway and telegraph construction. His Lordship said: "In these last two or three years we have constructed—I am now speaking of both the Transvaal and the Orange River Colony, which for railway purposes are happily one State—275 miles of railway. We are constructing 311 more. We have provided for 488 miles in addition—that is, upwards of 1,000 miles of line together. To look at the Transvaal alone, we have spent over £300,000 upon the repair and improvement of our telegraphs and telephones. I do not know whether it is due to that, but, at any rate in this year the service under the Postmaster-General will for the first time in its history show a surplus." With competition so keen in the home market, the need of finding an outlet abroad is constantly asserting itself, and manufacturers will act advisedly in keeping our South African Colonies well in mind.

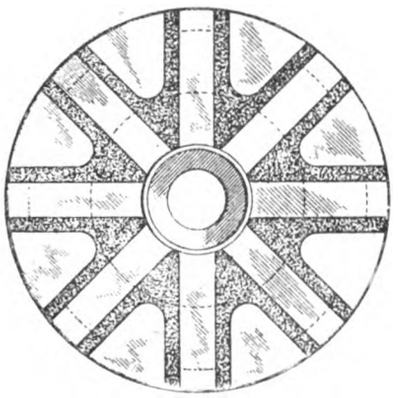
**Magnetic Clutch.**—A series of 12 patents, containing numerous claims, has been granted in the United States to Mr. H H Cutler in connection with a form of magnetic clutch and numerous applications of same. The distinguishing feature of the clutch consists of the means employed for controlling the accelerating torque so as to eliminate the undesirable jerk usually associated with magnetic clutches. The accompanying illustration, which we reproduce from the *Electrical World* of New York, shows a front view of the magnet member of the clutch. When the magnet is energised the triangular pieces become of one polarity, while the radially extending pieces are of the opposite polarity, the spaces between the poles being filled with non-magnetic Babbitt metal. The dotted lines indicate the location of the magnetising coil, which is surrounded completely with metal, which protects it from mechanical injury and from any detrimental effect due to oil employed for lubricating purposes. The Babbitt metal affords, with the polar faces, a continuous frictional surface against which the armature bears. The magnet member is thus so constructed that the energising winding is entirely surrounded by iron. The large inductance of the winding ensures that when the circuit is closed to a source of current, the current will rise gradually to its final value without giving to the driven member that sudden acceleration which has been the cause of serious objections to magnetic clutches of the ordinary type.



The inventor proposes to utilise both the torque due to friction and that due to eddy currents in the armature structure when there is motion between the two members of the clutch. For a certain magnetising force the frictional torque is practically constant during the period of acceleration, while the torque due to eddy currents uniformly decreases with increase of speed. By variation of the magnetising force any torque may be obtained at any speed up to full synchronism. The subdivision of the magnet into a large number of individual circuits aids in causing a rapid disappearance of the residual magnetism in the armature member when the magnetising force is removed, and thus allows the clutch to be released practically instantaneously. The more prominent applications of the clutch are for starting synchronous motors, throwing loads gradually upon motors, and for the operation of electric vehicles. When applied to an alternating-current motor the inventor would use a rectifier of either the aluminium or mercury vapour type for supplying direct current to the magnetising coil of the clutch.

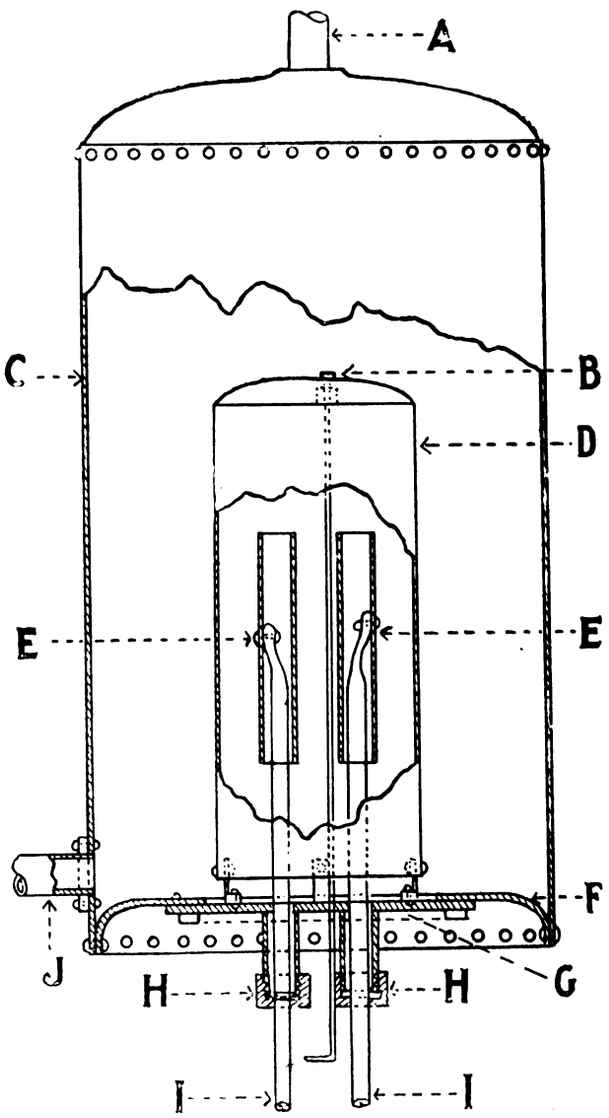
**Post Office Employes.**—The scheme of improved conditions of service prepared by Lord Stanley for the benefit of Post Office employés was discussed at the annual conference of the United Kingdom Postal Clerks' Association. It is pretty evident that the staff still hope to secure the full concessions recommended by the Bradford Committee, and general dissatisfaction was expressed at the revised rates of pay proposed by the Postmaster-General. In a resolution passed by the meeting it is stated that the Bradford Committee, which the Postmaster-General only consented to appoint after years of agitation, was composed of expert and impartial business men, who thoroughly investigated the question, and that the concessions now made are inadequate. There is no doubt that, as Lord Stanley has frequently stated, the Bradford Committee exceeded the terms of the reference, which has complicated the position. It was pretty generally acknowledged that the conditions of service stood in need of considerable amelioration, and perhaps the improvements proposed by the committee were not excessive, but they represented a substantial addition to the annual expenditure, and confronted Lord Stanley with the problem of doing justice to the staff and to the public at the same time. The concessions announced by his lordship appear to bring the conditions of service up to the average of those obtaining in other fields of an analogous character, and entail an increased expenditure of £224,000 for the first year and over £370,000 for subsequent years. There is doubtless room for further improvement, but it is to be hoped that the employés will not be too exacting in their demands. The Postmaster-General has also had his attention engaged by the National Telephone Company's staff, a deputation from which interviewed him last week with reference to their status on the transfer of the company's undertaking being completed. The deputation urged that the whole of the present telephone staff and operators should be taken over bodily by the Post Office when the transfer takes place, and submitted that under the present agreement for the transfer all members of the staff receiving a salary of £100 yearly and upwards, and who had contributed 2½ per cent. of their salaries to the pension fund with a view to making provision for their old age, would be deprived of this advantage. In the course of an informal discussion, the Postmaster-General intimated that, although he could not promise any particular individual that he would be taken on the General Post Office staff, he could safely promise that the telephone staff collectively would be employed under the new conditions. As to pensions, Lord Stanley explained that the Government pensions could not commence until the telephone employés had actually joined the Post Office service, but those telephone employés taken over would not have to wait 10 years before the pension started, as was the case when the present Post Office employés entered the service.

**Electricity in Coal Mines.**—The *Electrical Review* of New York publishes a description of the Hampton central power station, which has now been at work for two years supplying current to eight collieries in the vicinity of Scranton. The generating station is located near one of the collieries, from which its coal supply is drawn. The prime movers are Curtis turbines, of which four of 500 h.p. each have been installed. These run at 1,800 revolutions per minute, with steam at a pressure of 150lb. per square inch superheated 200deg. F. The alternators, which are directly driven from these turbines, are of the three-phase 60-cycle type, wound for 230 volts. The energy is transmitted at this voltage to all but one colliery, in the supply of which a higher voltage is needed, and step-up and step-down transformers are used. We do not need to give a description of the turbines, as they have already been illustrated in our columns. The interesting feature is that the power required for these eight collieries is all taken from the one generating station. The boiler-house equipment is of a thoroughly up-to-date character, with 15 Babcock and Wilcox boilers with mechanical stokers. The ashes are removed in a novel way, being

Digitized by Google

flushed from the ashpits with water, and the mixture is forced through a borehole into the mine. An interesting use of electricity in the immediate neighbourhood of the power-house will be a water hoist, now nearly completed, which requires an 800-h.p. motor to drive it. This water hoist is located about 500ft. from the power station, where a shaft 460ft. deep has been driven into the mines. The bottom of this shaft will drain all the mines in the immediate vicinity. Water will be hoisted from this shaft by means of two buckets suspended from a hoist tower over the shaft. Around the base of the tower has been built a concrete basin, into which the buckets will be emptied. The water will be piped from this basin to the boiler and turbine station, where such of it as is needed for condensing and other purposes will be utilised. The remainder will be carried on down the hill, and discharged into the Lackawanna River. The hoist tower is 93ft. from the base to the centre of the sheave at the top. It is built of structural steel, roughly in the shape of an A. From the tower are suspended two buckets 6ft. in diameter and 19ft. 6in. deep. The capacity of each bucket is 17 tons of water. In the bottom of the bucket are located two lift gates with an area practically equal to the cross-section of the bucket. These gates are lifted automatically when the bucket reaches the top, and the water is discharged through the bottom into a spout fitted below the bucket, and which deflects it to either side of the shaft. Each bucket makes a complete round trip in one minute and 55 seconds, the total lift being 555ft. The buckets are raised and lowered by means of an 800-h.p. induction motor running at a constant speed of 400 revolutions per minute, driving a pair of drums on which the cables from the buckets are wound. These drums are conical, in order to obtain a slow starting speed. The two diameters of the drum are 16ft. and 10ft. The motor is set at right angles to the drums, and motion is transmitted to the latter through a friction clutch and bevel gearing. Band brakes are placed at a number of different points, in order to make a quick stop if necessary. A good deal of the current used in connection with these collieries is converted from three-phase into direct current by means of rotary converters. The distance of the outlying collieries from the power-house ranges from two to four miles. In the different mines are installed 21 electrically operated hoists, worked by 28 motors with a total capacity of 1,915 h.p. There are 23 motor-driven pumps, the motors having a capacity of 1,571 h.p. In addition to this machinery there are installed 24 other motors for miscellaneous uses, having a total capacity of 318 h.p.

**Automatic Electric Water Heater.**—An electric water heater possessing the great advantage of being entirely automatic has been devised by Mr. A. C. Pratt, of the Missouri River Power Company, and is described in the *Journal of Electricity, Power, and Gas* of San Francisco. Its construction is based on the principle of a water rheostat operated under an inverted tank, all being enclosed in an outer tank. The inner tank contains the electrodes, E E, shown in the accompanying diagram. These electrodes, which are 1½in. apart, are subjected to a 500-volt 60-cycle alternating current. Any steam formed by the heating of the water rises within the inner can, and as its pressure increases it drives the water downwards, and consequently off the electrodes. This automatically controls the current consumption, and keeps the tank nearly full of steam, which in turn maintains the temperature of the water in the water-tank at a point near to boiling. The hot-water outlet, consisting of a 1in. pipe, is shown in the diagram as A; B is the air and steam vent pipe and valve; C is a 15-gallon galvanised iron tank; D is the steam-tank; F shows the concave bottom of the water-tank; G is a removable plate with a watertight gasket; H H are stuffing boxes; I I are extra-insulated rubber wires supplying current to the electrodes; and J is a 1in. pipe through which cold water is supplied to the tank. The particular form of apparatus described has been in service by the inventor's company for three years, and is still in operation. While its maximum current consumption when both tanks are filled with cold water is about 5 kw., this gradually decreases as the temperature of the water rises until it reaches a minimum of $\frac{3}{10}$ kw. No material electrolysis of the electrodes has occurred in the three years. A small valve is located at the hot-water outlet for the purpose of passing trapped air from the inner tank, or blowing steam from it, so as to hasten the heating of the water in the outer tank



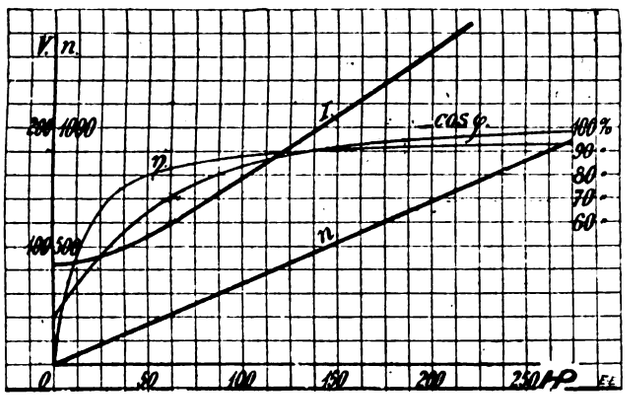
when an extra amount of hot water is needed quickly. The steam-tank and electrode are mounted on the bottom plate of the outer tank, to which they are attached by cap screws. It is desirable that the tank should be insulated, and that its inlet and outlet pipes should consist of rubber hose, to prevent the grounding of the current supply.

**Water Power in Upper Italy.**—A recent communication by Mr. Semenza before the Society of Civil Engineers of France on the above subject gives a *résumé* of the water power used in Upper Italy, and that which has still to be harnessed. The paper commences with some meteorological information as to the rainfall in the district in question, and also as to the general character of that part of the country. Practically all the water from the high-lying lands in the North of Italy finds its way eventually into the River Po. The author showed how by the ancient

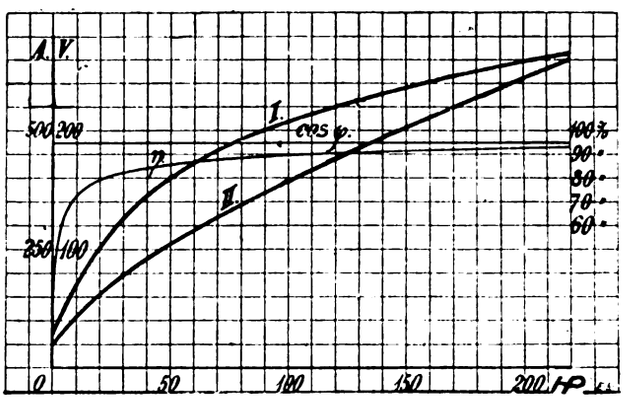
Digitized by Google

use of the water for irrigation and navigation the country had been prepared for its utilisation with more modern plant. The water power is the more valuable because Italy is almost without any combustible mineral. The Italian legislation for the transmission of electrical energy has co-operated with the above two conditions in the development of the industry. In order to facilitate the construction of water-power installations for the transmission of energy, a law has made it obligatory upon landowners to grant wayleaves over their property for the wires. Mr. Semenza gave a short history of the earlier electrical installations, and spoke of the one at Genoa as having been the first of considerable importance. It is, however, since the success of the Paderno installation that large water-power plants have begun to be constructed in Upper Italy. He then proceeded to describe the important installations which have been developed by different undertakers to serve the town of Turin. The water-power plants from which Milan and Monza are supplied were also described. These installations are remarkable for their size and completeness, and for the way in which the transmission lines are constructed. The author insisted on the importance of having iron supports for the line, and claimed that by these means the first cost was also reduced. One of the most interesting installations described was that of the Societa Lombarda, which distributes about 25,000 h.p. in a zone of some 550 square miles. In this zone there are no towns of importance, but the district is highly industrial. He then described the works which exist and those which are now under construction for the supply of the town of Genoa. In one of these the salient feature is that there are large reservoirs on one side of a mountain while the water-power plant is on the other. The water is led from one side to the other by tunnels. Amongst the large works there is also that of Venice, by which power is transmitted at 30,000 volts over a distance of 56 miles. The author then briefly described the equipments designed for the supply of small towns, or of factories and workshops. Only approximate figures as to the cost of supply and the charge for power were given, owing to limitations of time and space, but the author showed the effect of these schemes on the industries of the country. The development of these industries has during the past few years been very marked. His estimate of the total horse-power involved in such installations was 160,000, and that of the annual increase about 17,000. He considered that water power was likely to supersede the steam-engine in a large number of cases, and to permit of the development of existing industries and the creation of others. The author's conclusions as to the water power still available in the highlands of Italy for electrical transmission point to a large demand for electrical machinery in the near future.

**Single-Phase Locomotives.**—The Oerlikon Company has developed two types of single-phase alternating-current locomotives, with which extensive tests are to be carried out. The first of these has already entered upon regular service on the company's Seebach-Wettingen line. It was designed two years ago, at a time when there was still considerable scepticism regarding the feasibility of alternating-current single-phase traction, and the design was therefore based on the retention of direct-current motors for propelling the locomotive, and a means of converting the alternating current into direct current. The equipment of this locomotive includes a single-phase induction motor, with a speed of about 980 revolutions per minute when supplied with single-phase alternating current of 14,000 volts at a frequency of 50 cycles per second. This motor serves for driving a four-pole direct-current generator of 400-kw. rating, to which it is direct-coupled. The rotor has a short-circuit "cage" winding, and the stator has two windings—one designed for a potential difference of 14,000 to 16,000 volts and one of 700 volts. The second of these was provided in case it should be found desirable to use a low-potential third-rail line at the station or in the switch yards, instead of the overhead system. The high-potential winding, despite the severe strains to which it is subject, has not exhibited the slightest defect. The efficiency of the motor is about 94 per cent., with a power factor of about 89 per cent. at full load. The dynamo is designed for a full load current of 650 amperes and a voltage which can be varied



between zero and 600 volts. There is a 6-kw. motor-generator set, which normally serves for the excitation of the fields of the large generator, but can be employed to restore the speed of the large set should the latter chance to get "out of step." The second locomotive will be equipped with two 200-h.p. single-phase alternating-current motors, which can be operated under varying conditions, though designed more especially as alternating-current series motors for a voltage of 15,000 at a frequency of 15 periods per second. They are eight-poled motors, with inter-poles for the compensated winding, and are designed for maximum speeds ranging between 650 and 1,000 revolutions per minute. The results of tests with these motors are shown in the accompanying diagrams,



which we reproduce from the *Street Railway Journal*. The power factor is 94 per cent. at 650 revolutions per minute, and 97 per cent. at 1,000 revolutions per minute for all loads when the frequency is 15 periods per second, and it is 87 per cent. and 93 per cent. respectively with a frequency of 25 periods per second. In the first diagram the motor is run with a constant current of 600 amperes, with a frequency of 15 cycles. In the second diagram the motor is run at a constant speed of 650 revolutions per minute, with the same frequency. The motor was also tested for direct current work, and gave highly satisfactory results. In order to make the forthcoming tests as comprehensive as possible, the company propose to include an alternating-current motor of similar design to the above, but suitable for a higher frequency.

## THE ELECTRIFICATION OF GOODS WAREHOUSES ON THE LANCASHIRE AND YORKSHIRE RAILWAY.

BY VERAX.

Within the last decade a change has taken place in the personnel of the Lancashire and Yorkshire Railway, and a distinct improvement, correlatively, is noticeable in the company's method of working. The solution to the problems of (*a*) "quick dispatch of traffic between different towns" and (*b*) "the speedy liberation of wagons at the point of destination," has been found in a system whereby thousands of tons of merchandise are conveyed to and fro with the regularity of clockwork. Nowhere is the transformation more apparent than in the goods department, and the reason is, perhaps, not far to seek. Nowadays the travelling public are familiar with the sight of goods trains comprising 70 or 80 loaded wagons coupled to a powerful engine and safeguarded in the rear by two massive brake vans; such trains afford striking contrast to those of bygone years. At various points on the railway "refuge" sidings and loop lines are laid parallel to the main track, it being the duty of signalmen to divert and shelter these long freight trains whenever the electric bell gives warning of a passenger train approaching in the rear. Immediately after the block section becomes clear ahead, the refuge siding signal is lowered, and the freight train re-enters the main line, continuing its journey with a minimum of inconvenience and delay. In spite of adverse criticism, intelligent observers have not been slow to realise that long trains mean *fewer* trains, and that wagons loaded to their full capacity tend towards a diminution of rolling stock; consequently every mile saved is money saved, and the measure of success attendant on these efforts is the measure of general efficiency.

It is to the question of (*b*), speedily liberating and loading wagons, that we desire to confine our observations. It should not require elaboration on our part to convince the readers of the *Electrical Engineer* that it is not sufficient merely for the various termini to be staffed with men who understand their work, but what is of equal or greater importance, a complement of up-to-date machinery, capable of dealing promptly with goods on arrival, is an imperative necessity. The Lancashire and Yorkshire Railway evidently recognises that electrical energy applied to their goods warehouses and cotton sheds produces the best results. Hence the following brief survey describing what has been done in the direction named should be of interest to those enterprising manufacturers in a less pretentious line of business. It must, however, be clearly understood that the particulars following represent but a small percentage of stations more or less under electrification.

### BRADFORD.

As might be expected at an important centre of industry like Bradford, the goods station is electrically equipped with machinery of modern design. Prior to the year 1899 an ordinary mechanical outfit was the vogue, but the date named will be memorable in the annals of English history as the outbreak of hostilities in South Africa, and as such an event would presumably result in large army contracts for clothing and woollen goods generally, the railway company foresaw the prudence of better facilities to cope with the changed condition of affairs. An order was, therefore, placed with a Manchester firm for three electric travelling cranes, which were quickly got in working order. Each crane travels along parallel spans the entire length of the old warehouse. Built to carry a load of 15cwt. each, the lateral and longitudinal movements are quickly performed. Electrical energy is supplied along bare conductors and collected by means of gunmetal shoes. These cranes rendered good service and served to demonstrate the advantages of electric traction, so that in 1902 when the new Bridge street warehouse—fronting the Great Northern Victoria Hotel—was finished it was not surprising to find that complete electrification had been decided upon. Electric light was installed throughout. The lamps used were either incandescent, open arc, ordinary enclosed, or twin-carbon enclosed type, and the respective position of each kind was suggested from a glance at the geography of the place.

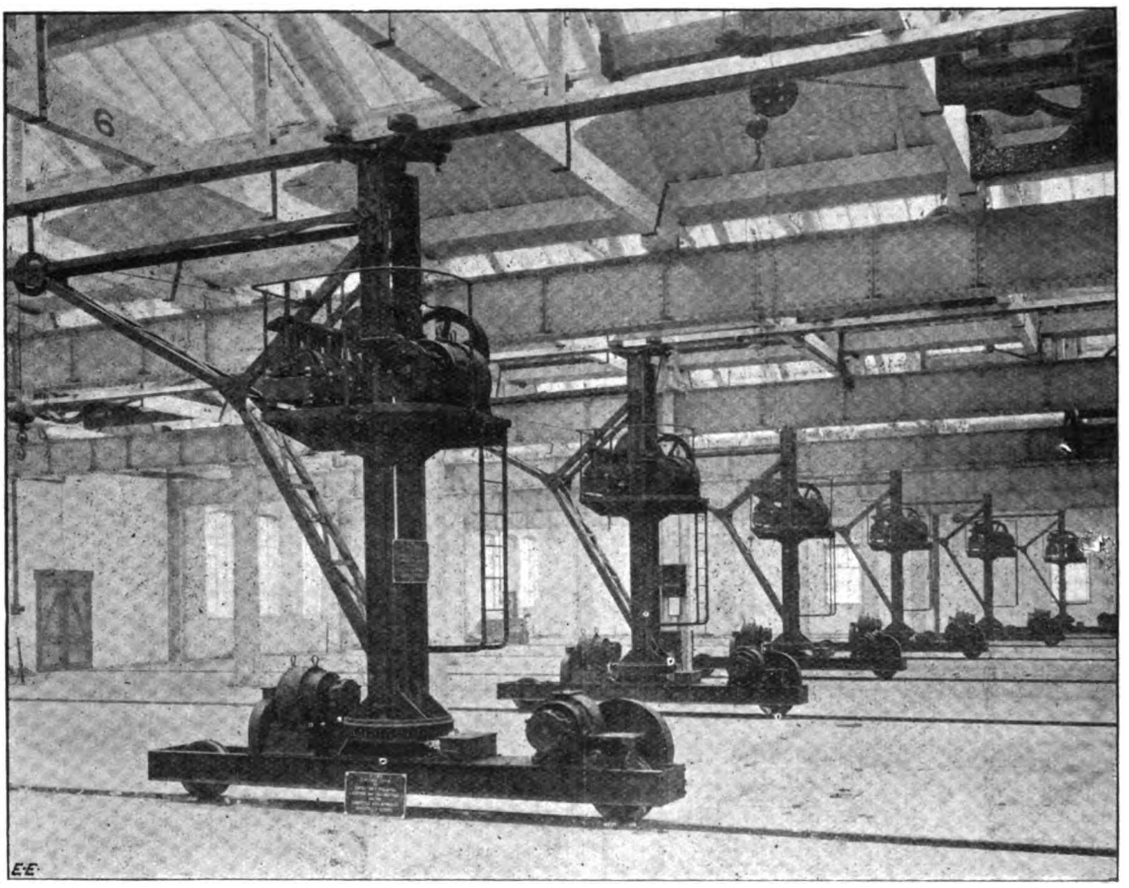

FIG. 1.—Crompton Single-Rail Walking Electric Cranes at the Bradford Depot of the L.Y.R.

Twenty-four "walking" cranes were built by Messrs. Crompton, Limited, three in the basement and seven on each of the three floors. The working load is 15cwt., and the travelling speed 150ft. per minute. A 10-h.p. motor running at 700 revolutions per minute with magnetic brake

Digitized by Google

on the motor spindle controls the lifting motion. The slewing movements are actuated by a 2-b.h.p. motor, and the magnetic brake connected thereto is arranged to come into operation when the circuit is broken. Current from the mains is connected by gunmetal shoes along two bare copper wires strained inside the top guide channel. On the driver's platform a combination three-motor controller is fixed for starting, stopping, and reversing any of the three motors. A double-pole switch and fuse is also provided for isolating each crane. The driver's cage is fixed on the pillar of the crane and works with it, so that the driver and the jib head are always in the same relative position. A general view of these cranes is shown in Fig. 1.

An electric lift was requisitioned about this time from the last-named firm for the conveyance of small goods packages between the basement and top floor or intermediate rooms; packages such as would be too heavy for a workman to carry up a flight of steps, yet too light to be dealt with efficiently by the main electric hoist. On the occasion of our last visit, immense quantities of wool were being hauled from different sections of the new warehouse to freighters' lorries in the street below, suitably designed motors being used in connection therewith. All the machinery is maintained in good working order; indeed, the only serious stoppage occurred in December last, when the Corporation mains unfortunately took fire at various parts of the city. Possibly the railway officials derived *some* consolation from the thought that other firms were in a similar predicament.

FIG 2.—Electric Capstan at Halliwell.

### MOSES GATE

This station is on the main line between Manchester and Bolton, the goods warehouse being fitted up for the reception of Egyptian cotton and other commodities. Goods may be transferred direct from railway wagon to carter's dray if required, but when large consignments arrive it frequently happens that mill owners, etc., through lack of accommodation at their respective depôts, are not in a position to receive the whole of their goods at once; consequently the railway company proceed to hoist what remains of the consignment to the second or third storey of the warehouse before mentioned. The mechanical power necessary in operations of this kind was formerly obtained from a small engine and boiler situate in a building near the "enquiry" office, but when the Farnworth Urban District Council commenced running electric cars, arrangements were made for a supply of electrical energy on the usual day-load motor terms. A paper-insulated armoured cable was laid from the District Council's meter box to the top storey of the warehouse, and connected through the usual fuses, switches, and rheostat to a multipolar shunt-wound motor. This machine was designed and built at the chief locomotive works, Horwich. As soon as the substitution was complete a vertical shaft 60ft. long, together with pulleys, cranks, and bevelled wheels, were scrapped, and the engine and boiler loaded in a wagon. The engine-man was no longer required, and his services have been more usefully employed elsewhere. Moreover, the valuable space which the power plant occupied was soon put to better use; after the walls were beautified, a National telephone was connected, and the room fitted with desk accommodation for a staff of clerks who are now busily engaged therein.

### HALLIWELL.

As many of our Lancashire readers are aware, Halliwell is a populous district within the borough of Bolton. Except at the outskirt, it cannot boast of many verdant fields, still less of luxuriant foliage, but its cotton mills and ironworks provide employment for thousands of willing hands. Railway companies, as a rule, are not slow to discern in what direction business lies, and the goods station at Halliwell is a fair embodiment of that proposition. A large tract of land was acquired in this district many years ago, the total area exceeding the actual requirements at the time. Within recent years, however, a development of business has taken place necessitating an additional warehouse, which has been erected on the spare ground referred to. Instead of enlarging the existing steam plant, it was resolved to equip this new building with the latest type of electrical machinery and obtain current from the Bolton Corporation electric supply system. The pavement was accordingly dotted about with electric capstans, and by the time these were connected to the power mains two overhead electric travelling cranes had been erected and finished. Before the work of electrification could be considered complete, arc lights were needed to illuminate the warehouse and goods yard; hence 20 open-type lamps with automatic cut-outs and compensating resistances, were duly installed—five in series on a 230 volt circuit.

A brief description of the capstans and cranes, both of which work at a pressure of 460 volts, will perhaps be opportune. There are 11 capstans in all, designed and manufactured by the railway company. These appliances resemble in general configuration a capstan on board ship; the latter, however, is mechanically driven, while the former are electrically operated. An 18 b.h.p. series-wound motor is fixed below pavement level, the armature shaft being geared to the capstan bell. Ball thrust bearings are provided, and these, together with the worm gearing, are immersed in an oil bath, compact and out of sight. By the aid of a stout rope lashed several times round the capstan bell and hooked to a distant truck, it is only

Digitized by Google

necessary to depress a pedal, when current is supplied to the motor and the capstan commences to revolve. Loaded wagons are thus drawn into this new shed and hauled out again when empty. The photograph reproduced (Fig. 2) was taken under actual working conditions, but a critical eye will detect the brakes momentarily pinned down to secure a taut rope.

With reference to the overhead electric cranes, we should explain that 30ft. above loading stage two railway lines were laid longitudinally, one on either side the warehouse wall. It is along these metals that the cranes travel. The span is a much longer one than those at Bradford—namely, 75ft. 6in., the longest, we believe, of any span traversed by an electric crane—and it has been necessary to make the end carriages proportionally stronger to carry the latticed ironwork structure with the usual margin of safety. These cranes, depicted in Fig. 3, lift 30cwt. each, and get through an immense amount of work per day, rapidity of movement being the distinguishing feature. The contracting firm was Messrs. Crompton, Limited, London.

FIG. 3.—Electric Travelling Cranes in operation at Halliwell Goods Warehouse.

PRESTON.

For a longer time than we have data to tabulate, the famous old town of Preston has had two keen competitors for the bulk of its traffic—viz., the London and North-Western and the Lancashire and Yorkshire Railways respectively. With the commencement of the present year, however, business rivalry ceases, a reciprocal arrangement having been entered into for a period of 50 years, with advantage, we are assured, to the general public. Nevertheless, a cursory glance at what the last-named company has done at their warehouse on the East Lancashire side, previous to the above agreement, may not be without

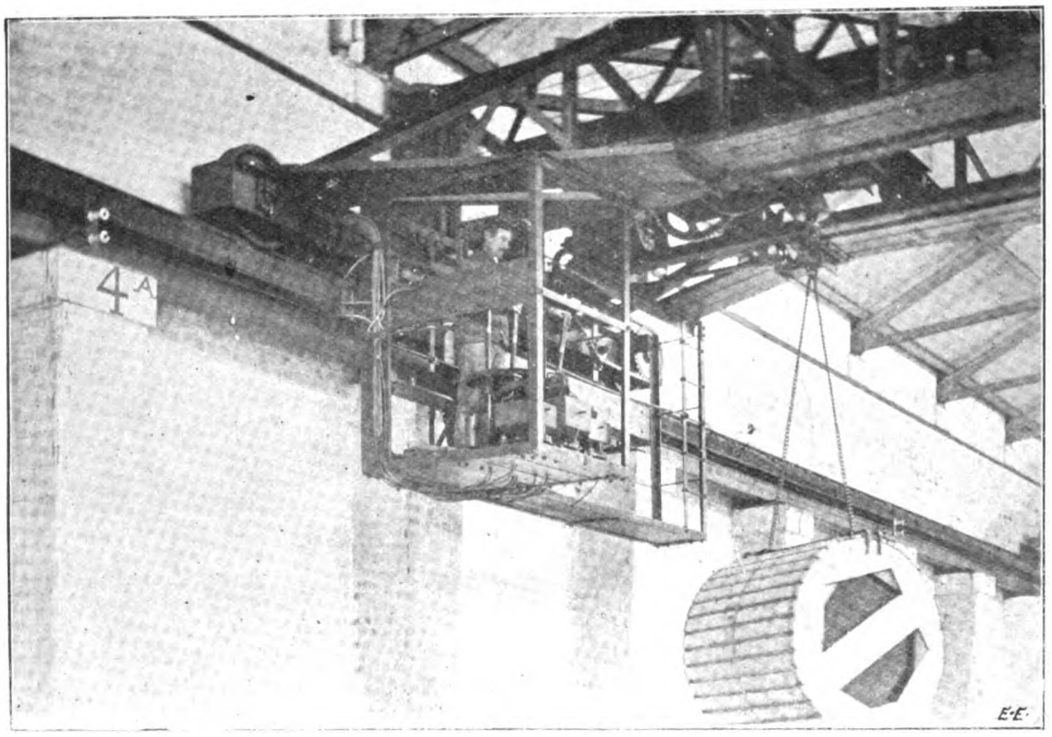

FIG. 3A.—Details of Driver's Cage of the Halliwell Cranes.

Digitized by Google

interest at the present juncture. In short, the time had arrived when the old steam plant should either be thoroughly overhauled or scrapped. The latter was decided upon, and in lieu thereof one of Messrs. Mather and Platt's shunt-wound motors was installed in the topmost storey, together with an automatic starting rheostat of Messrs. Sturtevant's design. The function of this motor is limited to "jigger" work—admittedly a rather ambiguous term, but sufficiently comprehensive amongst railway men. A bale of cotton has sometimes to be raised through four or five trap doors to a height of 100ft., and the "jigger" motor supplies the power, electrical energy being served from the Preston Electric Supply Company.

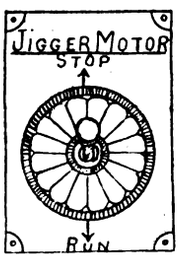

FIG. 4.

A novel feature in connection with the starting resistance is the presence of a number of eight-ampere tumbler switches joined in parallel, one fixed near each trap door (Fig. 4). The motor can be started from any of the tumbler switches, and not until *all* these have been turned to "STOP" will the motor cease running. There would be an objectionable waste of time and electrical energy were it necessary to stop and start the motor always at the top floor, and this is obviated in the manner explained, whilst the electrical connections are shown diagrammatically in Fig. 5.

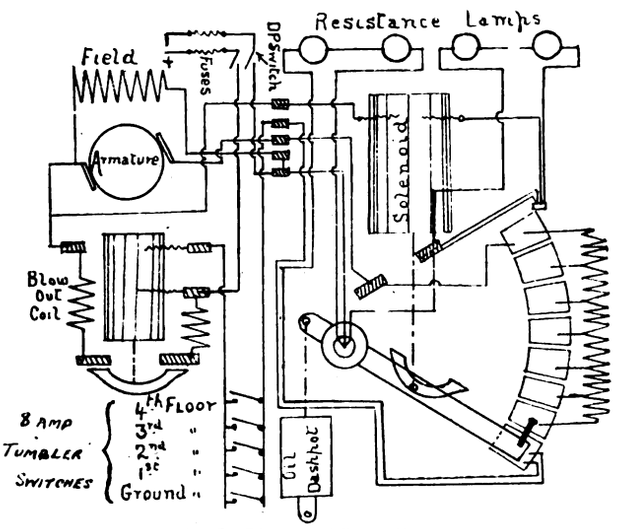

FIG. 5.—Diagram of Connections.

Many of the foregoing items may be regarded by some as minor detail in railway management, but it should not be overlooked that close attention to *detail* is an important factor in the art of success.

## THE LAHMEYER OIL TESTER.

BY H. E. HODGSON.

In large factories and power plants where there is always a large quantity of machinery continuously in operation, it is very necessary to use the highest grade of lubricants obtainable. And as the lubricants often constitute a considerable portion of the working expenses, it is very desirable before purchasing a quantity to thoroughly test the various oils in order to determine the right kind of oil to use in a particular piece of apparatus, as well as to be able to ascertain whether subsequent shipments come up to the original standard. A compact machine for testing lubricants is that made by the Lahmeyer Electrical Company (Elektricitäts Aktien-Gesellschaft of Frankfort). In this machine, which is shown in section in Figs. 1 and 2, the bearing in which the lubricant is tested is situated between two flywheels, F F (shown in Fig. 3), which is an outline drawing of the commercial form of the apparatus, the weight of the wheels producing the ordinary pressure on the bearing, which in this apparatus is about 44lb. per

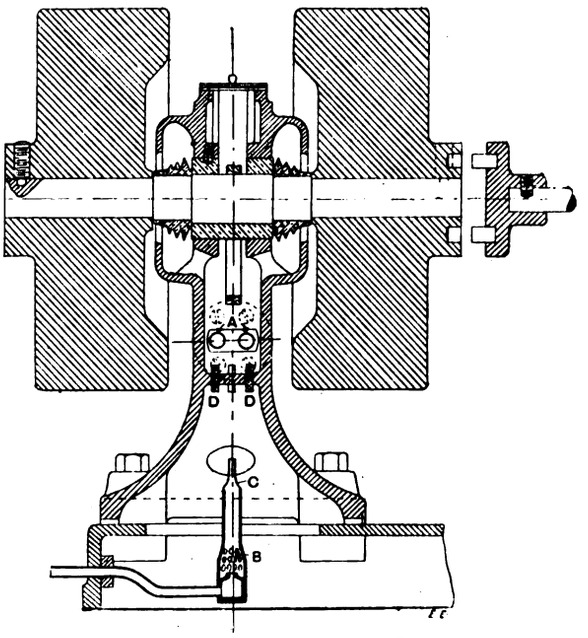

FIG. 1.—Section through Axis of Oil Tester.

square inch.* The bearing pedestal forms the oil reservoir, into which dips a lubricating ring, by which a constant stream of oil is fed into the bearing. The bearing brasses are all in one piece in order that a constant mean thickness of lubricant can be maintained at all loads; it having been found that with divided brasses the mean thickness of the lubricant decreases with the load, causing an increase in the frictional resistance.

The apparatus is designed to be driven by an electric motor, by mechanical means, or by hand. Probably the most convenient method of driving is by means of a variable-speed continuous-current motor, which is the method shown in Figs. 3 and 4. The motor, which has an

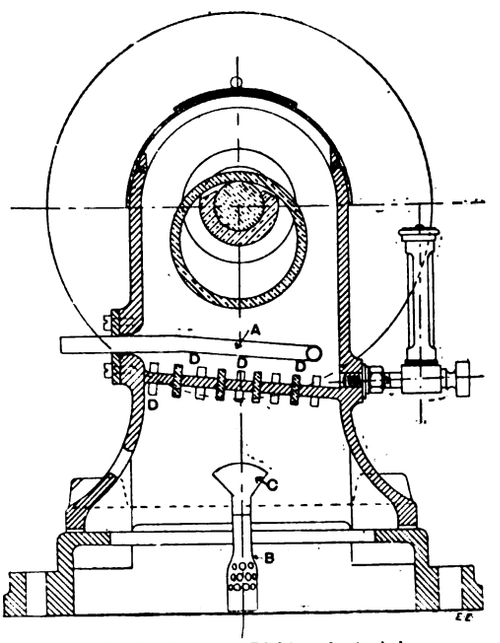

FIG. 2.—Section at Right-angles to Axis.

output of $\frac{1}{8}$ h.p. at 100 volts and 1,800 revolutions per minute, is mounted on a common base-plate with the oil-testing machine, and drives the latter by means of the dowel clutch, G (Figs. 1 and 3). The starting and regulating

* The makers also supply auxiliary flywheels, a pair of which are shown in position in Fig. 7, by means of which the pressure on the bearing can be increased about 70 per cent.

Digitized by Google

resistances, which are placed in the base-plate immediately underneath the motor, are connected to the switch, S, as shown in the diagram of connections (Fig. 5). From this it will be seen that the first four stops constitute the starting resistance proper, while the remaining stops are for speeding up the motor by putting resistance in the field, thus obtaining a considerable range of speed. When the

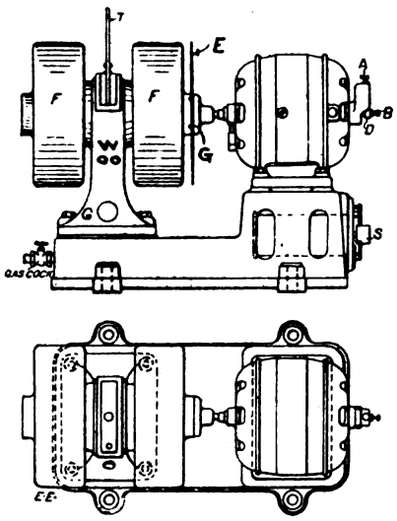

FIG. 3.

clutch plate, G, is moved away from the wheels, the dowels come out of their respective recesses, and the motor is entirely separated from the wheels. The separation is effected in the following manner: The motor spindle has a certain amount of end play, and the armature is compelled, when the clutch, G, is in gear with the wheels, to run slightly out of its central position by means of a hardened

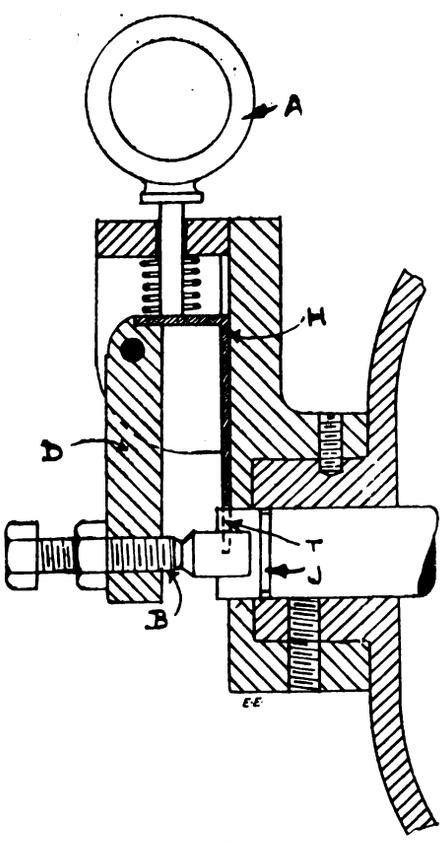

FIG. 4.

set screw, B (Fig. 6), in the end of the hinged arm, D, the arm being held in position by the catch-pin, H. Now, when an armature is displaced in the direction of its axis from its magnetic central position, the field magnets try to pull it back again. Hence when the arm, D, is released from its vertical position, by lifting the catch-pin, H, the armature automatically restores itself to its central position and withdraws the clutch plate, G, from the wheels. After A is lifted and the clutch disengaged from the wheels, the catch-pin should be allowed to regain its original position, and in so doing compels a fork, T, to descend astride the spindle into a circumferential groove, J, cut in it for the purpose, thus holding the motor spindle in its central position and maintaining the clutch free from the wheels. To couple up again, which must be done after the wheels have come to rest, simply press in the set screw, B, while the wheels are turned gently by hand until the dowels fall into their respective recesses. The catch-pin, H, then holds the arm, D, in position until the clutch is again disengaged by lifting A.

When an alternating-current motor is used to drive the wheels, as shown in Fig. 7, a separate starting resistance is employed, and the uncoupling mechanism is of slightly different construction. A dowel clutch is still employed for transmitting the power to the wheels, but in this case it is held in position by a lever shown in Fig. 7, and is withdrawn by means of a spring which is brought into action by depressing the lever. A mechanically-driven apparatus

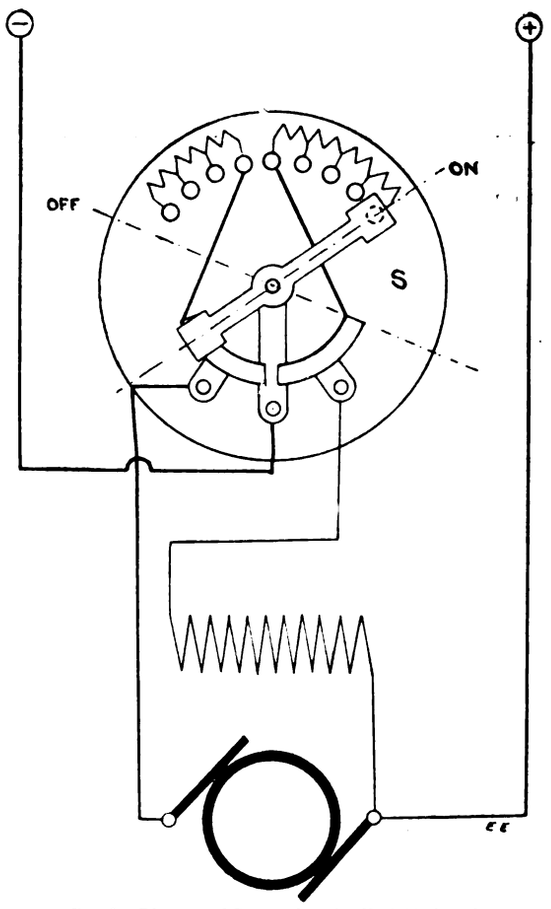

FIG. 5.—Diagram of Connections for Variable-Speed Continuous-Current Motor.

is shown in Fig. 8, from which it will be seen that the machine proper is of exactly similar construction to the one just described. In the type where hand driving is resorted to, two small reduction gear spindles are arranged so as to obtain a speed of from 1,500 to 1,700 revolutions per minute at the flywheel spindle.

For measuring or testing the quality of an oil, the so-called running-down system is employed, which consists in running the flywheels up to speed, uncoupling, and allowing them to run down to rest, their kinetic energy being dissipated in overcoming the frictional resistance of the lubricant. In the ordinary way, to compare two oils it is only necessary, as will be seen latter, to note the time taken with each oil for the flywheels to come to rest from a certain speed. For the purpose of measuring the speed the makers supply a special form of speed counter (Fig. 4), which can be connected to the end of the spindle by means of a suitable coupling. This counter has two hands like a watch, the long one indicating tens and the short one the hundreds, and is furnished with a small knob at the side which serves to rapidly adjust the hands to zero. The

Digitized by Google

counter is used in the following manner: After the wheels have been run up to speed, the counter is connected up and the number of revolutions made in a known interval of time observed, the second reading of the counter being taken with it in motion. The counter is then disconnected, the motor uncoupled, and the wheels allowed to run down. Where the tester is used for scientific purposes, besides knowing the time of running down, the actual shape of the running-down curve is usually required, which necessitates the speed being observed several times while the wheels are running down.

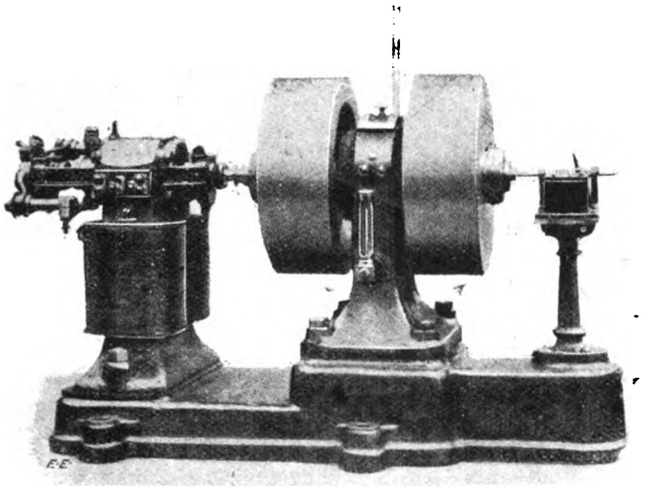

FIG. 6.—Oil Tester coupled to Continuous-Current Motor, showing Speed Counter.

To obtain the whole curve in one run with the ordinary counter, the latter must be connected up during the whole time that the flywheels are running down, which will introduce considerable error. Of course, the curve could be obtained by taking a series of runs with different initial speeds, the speed in each case being measured before uncoupling, as described above. But besides making the taking of a single curve a long and tedious operation, the method tends to introduce irregularities due to varying conditions unless very great care is exercised. In order to enable the running-down curve to be obtained during one run, without introducing the error due to the speed indicator requiring a certain amount of power to drive it, the apparatus used by the writer has been fitted with a

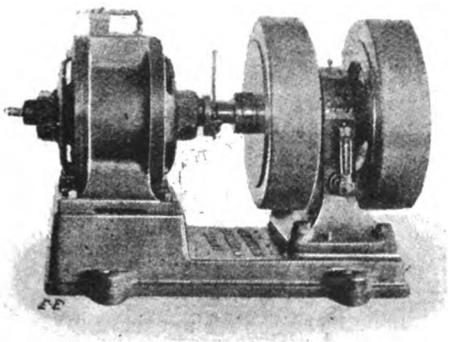

FIG. 7.—Oil Tester coupled to Induction Motor, showing Auxiliary Flywheels in position.

stroboscopic speed indicator and an autographic time-recording apparatus. The stroboscope consists of a sheet-iron plate, E (Fig. 3), having the same diameter as the flywheels, and rigidly fixed to the dowel plate, G—*i e*, to the motor spindle. This disc has an hole about 1in. diameter cut near the circumference, and on the flywheel are painted 10 corresponding white spots. When both the wheel and the disc are rotating in the same direction, and the white spots are observed through the hole in the disc, the spots in general will appear to be moving in one direction or the other; when the spots appear stationary the wheels are running at either ·1, ·2, etc., times the speed of the disc—*i e*, of the motor. This effect may be briefly explained as follows: Suppose the motor and its attached disc containing one hole to be running at 2,000 revolutions per minute, and the wheels to be running at 1,800 revolutions per minute—that is nine-tenths as fast as the disc. Then if spot No. 0 coincides with the aperture in the disc at the top of one revolution, at the next revolution the spot No. 9 will coincide. Thus, so long as the wheels run at nine-tenths the speed of the motor, and so lose one interval per revolution, there will always be a spot to coincide with the aperture. As the disc is making 2,000 revolutions per minute, each spot will be viewed 2,000 times a minute, and an apparently stationary series of spots will result. If the speed of the wheels is decreased

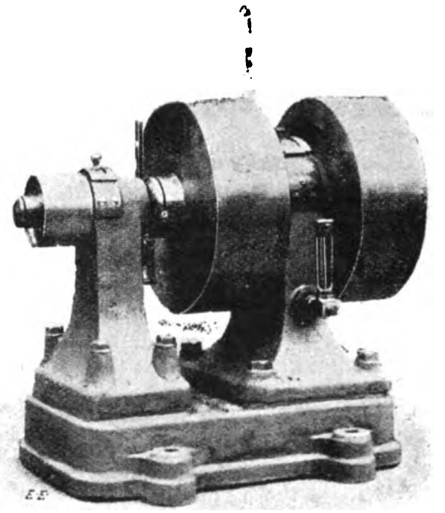

FIG. 8.—Oil Tester arranged for Mechanical Driving.

they will lose a little more than one interval per revolution, and the spots will drift backward until the wheels lose 1½ intervals per revolution, when they will drift in the opposite direction till the wheel loses two intervals per revolution, when they will again appear stationary; the coincidence being now given by every eighth spot, the speed of the wheels being eight-tenths that of the disc.

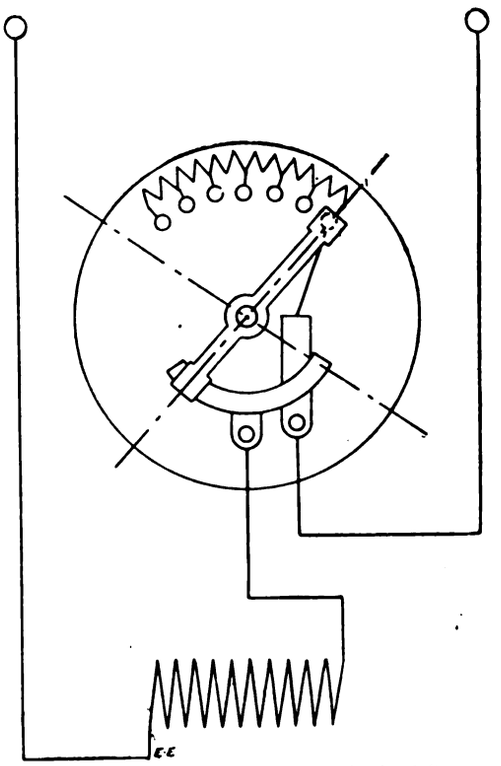

FIG. 9.—Diagram of Connections of Heating Coil.

The recording gears consists of an ordinary Morse telegraph recorder, the energising circuit being completed through a seconds pendulum and a mercury cup. The time of the spot being stationary is recorded by depressing a spring tapper key, which is in parallel with the pendulum and makes a somewhat longer dash on the tape than those made by the pendulum. The speed of the motor should

Digitized by Google

be observed once or twice while the wheels are running down by means of a tachometer.

In order to ascertain the effect of heat on the oils under test, the apparatus is provided with suitable heating appliances. To obtain the lower temperatures such as are usually met with in bearings, a copper heating coil (A, Figs. 1 and 2) is fitted in the oil container, through which hot water or steam at atmospheric pressure can be circulated. The oil should be warmed up while the machine is standing still till the temperature is raised to about 25 per cent. higher than that required while the machine is running. The cooling action which takes place when running up will then bring it down to about the right temperature. To ascertain the effect of cold, the same coil can be used for circulating cold water or brine instead of hot water.

The higher temperatures—*i.e.*, up to 200deg. C.—are obtained either by means of an electrical heating coil in the oil container or by means of a gas-burner in the pedestal. In the case of electrical heating, the coil, which takes a maximum current of about two amperes, is connected up to the regulator, as shown in Fig. 9. The maximum current should not be allowed to flow immediately through the coil, but the current should be gradually increased by cutting the regulating resistances out of circuit, thus obtaining a more gradual and uniform rise of temperature. Great care should always be taken before switching on the heating coil to see that there is a supply of oil in the container, as otherwise there is a considerable risk of the coil being burnt out. For heating by means of gas, a specially constructed Bunsen burner, B (Figs. 1 and 2), having a fan-shaped mouthpiece, C, is fitted underneath the oil reservoir, the bottom of which contains a number of copper pins, D, to facilitate the conduction of heat into the oil. Some skill, however, is required to manipulate the gas heating satisfactorily, owing to the fact that the variation of the oil temperature lags considerably behind the variation of the size of the flame. A good plan for temperatures up to about 150deg. C. is to vary the flame as little as possible and regulate by means of cold water flowing through the copper coil. The temperature of the oil is measured by a mercury thermometer, T, which passes through an aperture in the cover of the bearing and dips in the oil to about the same depth as does the lubricating ring. This thermometer, unfortunately, does not give any information as to the temperature of the bearing itself, and hence one would expect rather uncertain results, especially at the higher temperatures. This uncertainty can be minimised to a large extent by running the machine for some time at a constant temperature before attempting to take any readings.

The theory of the machine may be gathered from the following :

Let W = weight of the wheels ;
$r$ = radius of gyration of the wheels ;
$v$ = velocity of a point at the outer end of the radius gyration ;
$n$ = number of revolutions per minute made by the wheels ;
E = kinetic energy stored in the wheels ;
T = time in seconds of running down from $n$ revolutions per minute to rest.

Plot the speed vertically and the time of running down horizontally, and let the suffixes 1 and 2 refer to any two points on the time speed or running-down curve. Then

$$E_1 - E_2 = \frac{W}{2g}(v_1^2 - v_2^2);$$

and as

$$v = \frac{2\pi r n}{60},$$

$$E_1 - E_2 = \frac{W r^2}{2g \times 90}(n_1^2 - n_2^2).$$

Now $E_1 - E_2$ equals the energy used in doing work against the frictional resistance of the oil during the interval of time $T_1 - T_2$ seconds, hence the total work done per second

$$= \frac{E_1 - E_2}{T_1 - T_2}$$

If we assume the average resistance offered by the oil over this time to be R, then the work done per second equals R × distance moved by the surface of the journal per second, which is equal to $R \times \frac{\pi d n}{60}$, where $d$ equals the diameter of the journal and $n$ is the mean speed during the interval of time considered. These are two expressions for the same amount of work, and must therefore be equal ; hence

$$\frac{R \times \pi d \times n}{60} = \frac{E_1 - E_2}{T_1 - T_2}.$$

Replacing $E_1 - E_2$ by its value found above we have

$$\frac{R \times \pi d \times n}{60} = \frac{W r^2}{180\, g}\left(\frac{n_1^2 - n_2^2}{T_1 - T_2}\right),$$

or,

$$R = \frac{W r^2}{9{\cdot}4\, g\, n\, d}\left(\frac{n_1^2 - n_2^2}{T_1 - T_2}\right),$$

and since $n = \frac{n_1 + n_2}{2}$,

$$R = \frac{4 r^2}{4{\cdot}7\, g\, d}\left(\frac{n_1 - n_2}{T_1 - T_2}\right).$$

It is customary to speak of the area of the bearing as its length multiplied by its diameter. If we let $\rho$ be the specific resistance of the lubricant—that is, the resistance per unit of projected area—then

$$R = \rho\, l\, d,$$

and

$$\rho = \frac{R}{l \times d} = \frac{W r^2}{4{\cdot}7\, g\, d^2 l}\left(\frac{n_1 - n_2}{T_1 - T_2}\right).$$

Now the quantities W, $r$, $d$, $l$, and $g$ are all constant in this machine. Hence we may write $c$ for the quantity of the left of the bracket. Then

$$\rho = c\frac{n_1 - n_2}{T_1 - T_2}.$$

It will be observed that the fraction in this equation is the slope of the running-down curves between the points considered. The value of $c$ for this machine when the dimensions are measured in metric units is 0·01368, the intensity of pressure on the bearing being expressed in kilogrammes per square centimetre. It was found by Beauchamp Tower that the resistance $\rho$ is proportional to the square root of the speed when the speed is above a certain small critical value where solid friction comes in. Hence we have $\rho = m\sqrt{n}$, but $\rho$ also equals

$$c\frac{dn}{dt},$$

therefore

$$\frac{dn}{\sqrt{n}} = \frac{m}{c}\, dT.$$

Integrating we have

$$2\left[\sqrt{n}\right]_2^1 = \frac{m}{c}\left[T\right]_2^1$$

or,

$$\sqrt{n_1} - \sqrt{n_2} = \frac{m}{2c}\left[T_1 - T_2\right]$$

but

$$m = \frac{\rho}{\sqrt{n}}$$

then

$$\frac{\sqrt{n_1} - \sqrt{n_2}}{T_1 - T_2} = \frac{\rho}{2c\sqrt{n}}$$

and

$$\rho = 2c\sqrt{n}\left(\frac{\sqrt{n_1} - \sqrt{n_2}}{T_1 - T_2}\right) \quad . \quad . \quad (1)$$

The fraction $\frac{\sqrt{n_1} - \sqrt{n_2}}{T_1 - T_2}$ is as nearly as possible constant for any one running-down curve, hence we get $\rho = K \times \sqrt{n}$, where K is the characteristic constant of the oil.

When considering a point on the running-down curve, some distance from rest, the equation (1) can be written $\rho = 2c\frac{n}{T}$, where $n$ is the starting speed and T the time in seconds of running down to rest, without introducing any sensible error. And as when taking a test the starting speed is always high (1,800 to 2,000 revolutions per minute),

Digitized by Google

this equation can be used to determine the constant K, which then equals $\frac{2c\sqrt{n}}{T}$.

The machine is used in the following manner: Drain from the reservoir any oil it may contain and thoroughly clean it first with paraffin, and afterwards with benzine, the former being run off before the latter is applied. When the latter is run off, the bearing should be well blown out with a pair of bellows, while the wheels are slowly rotated by hand, to thoroughly dry it. The reservoir should now be filled up to the mark on the gauge glass with the oil to be tested, and the temperature

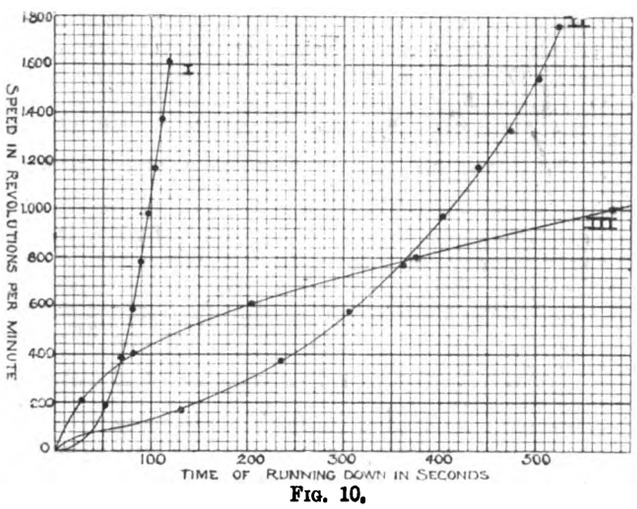

FIG. 10.

adjusted as previously described. The clutch is then thrown in gear, and the machine is ready to start. Turn the lever of the starting switch, S, on to the first contact, and allow it to remain there until the speed of the wheels does not appear to increase. The lever can then be moved on to the second contact, and so on. Especial care should be taken to see that the oiling ring is working properly, and is not prevented from rotating by the thermometer or connections to the heating resistance. When the desired speed is obtained it should be measured either by means of a tachometer or a revolution counter; the temperature should then be observed and the motor disconnected, and a stop-watch started. The motor should now be switched off, and should not be started again till the wheels have come to rest and the clutch put into gear. When the wheels come to rest, the stop-watch should be stopped and the temperature again noted. Should the mean temperature in any two trials not be the same, it may be corrected on the assumption that K varies inversely as the temperature.

Fig. 10 shows three typical running-down curves. Curve I. was taken with "Valvoline" cylinder oil, K at 30deg. C. = ·00930; Curve II. was taken with "White Loom" machine oil, K at 30deg. C. = ·00221; and Curve III. was taken with paraffin oil, K at 30deg. C. = ·000989. A few other oils may be cited to show the order of K: "Vacuum" gas-engine oil, at 27deg. C. = ·00313; vacuum cylinder oil, K at 27deg. C. = ·0139; "Vacuum" engine oil, at 30deg. C. = ·00261; "Vacuum" marine engine oil, at 30deg. C. = ·00255. Fig. 11 shows some running-down curves taken at different temperatures with "Valvoline" cylinder oil; the value of K and the temperature is marked near each curve.

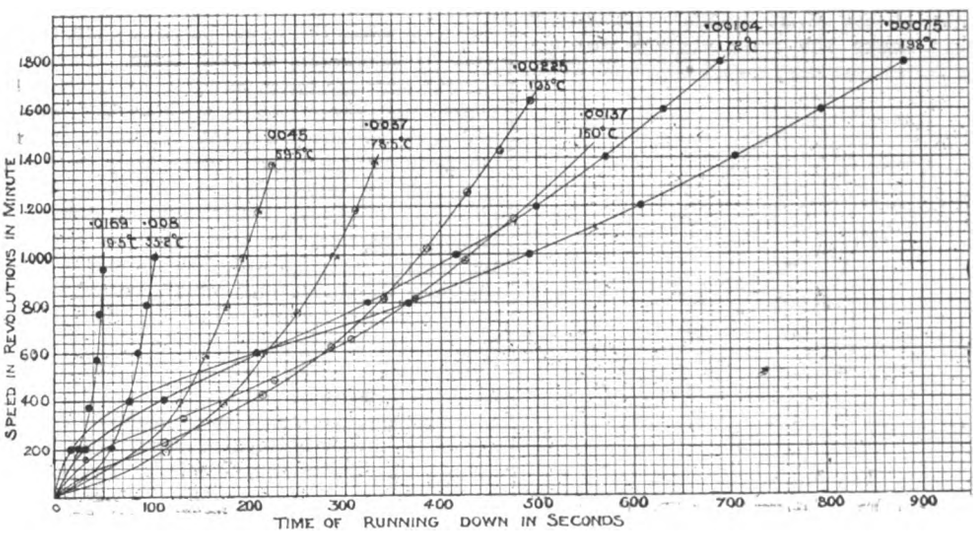

FIG. 11.

## THE ALTERNATING-CURRENT SERIES MOTOR.*

BY F. CREEDY, STUDENT.

Within the last few years much attention has been devoted to various forms of single-phase commutator motor, in the hope of finding, in some of them, a solution of the problem of electric traction by alternating currents.

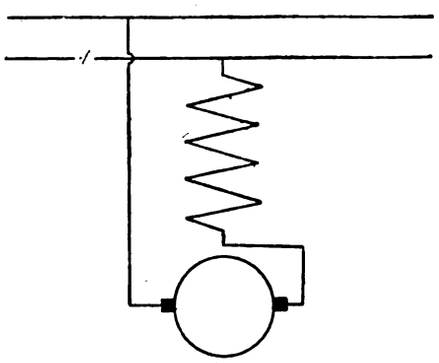

FIG. 1.

One of the most successful of these motors appears to be the old-fashioned alternating-current series motor, which is now coming into commercial use for railway work. The following paper is an account of some investigations carried out at the Central Technical College between March and July, 1904, which are intended to show the effect, on the performance of the motor, of varying the elements of the design. I propose, in the first place, to deal with the theory of the series motor; next, I give an account of a series of experiments verifying the theory; and lastly, an account of some experiments on the commutation of these machines.

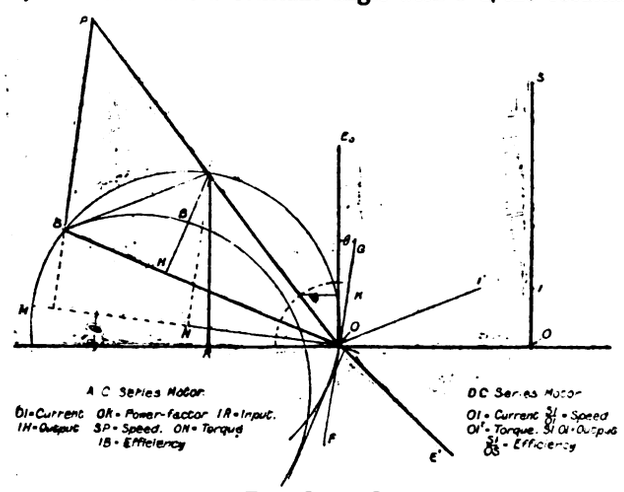
### THEORY OF THE SERIES MOTORS.

The simplest way to study the theory of the series motor is, as in the case of many other motors, by means of its circle-diagram. I describe below a circle-diagram which I worked out for this motor some time ago, showing very clearly the leading characteristics of the machine. This diagram (Fig. 1) may easily be deduced as follows: The motor at standstill is a mere choking coil, and a current, O S (see Fig. 2), will flow in it, such that the

* Paper read before the Institution of Electrical Engineers.

Digitized by Google

vector sum of all the E.M.F.'s in the circuit (the impressed E.M.F. and those induced by the current) is zero. Consequently, if another E.M.F., such as the counter E.M.F. produced by the rotation of the armature, be applied to the circuit, it will produce a further current, O I′ = S I, lagging behind it by a certain fixed angle. The vector sum of this current and of the standstill current, O S, will be the resultant current, O I. Now, since the counter E.M.F., O E′, of the motor is exactly in opposition to the resultant current, except for a small but constant angle due to the iron losses, and the current S I = O I′ lags by a constant angle behind it, S I must make a constant angle with O I, the resultant



FIGS. 2 AND 2A.

current. Since O S is constant and O I = O S + S I vectorially, O I must obviously move on a circle passing through the origin. In Fig. 2 the angle S I O is equal to the angle I O I′, since O I′ and S I are parallel. Now the angle between O S and O $E_0$ is the same as that between O E′ and O I′. Consequently, if $\theta$ is the small angle of phase difference between counter E.M.F. and current, and if O E′ leads O I by an angle $\pi - \theta$, O I′ will lead O I by $\pi - \theta - S O E_0$. Thus

$$S I O = \pi - (S O E_0 + \theta) = S O F$$

where the line F G makes the angle $\theta$ with O $E_0$; but, by Euclid, this is the condition that F G shall touch the circle at O. The diameter of the circle passing through the origin will, of course, make the same angle $\theta$ with the line of zero power factor that the tangent does with O $E_0$.

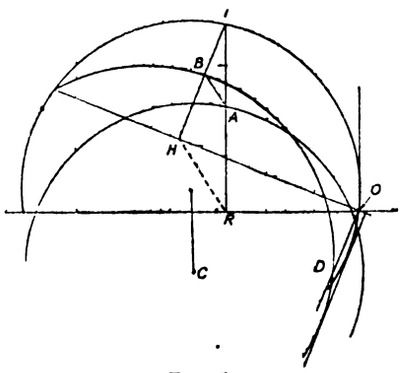


FIG. 3

Since S I is proportional to the counter E.M.F. of the motor, it must be proportional to the product of speed × flux, or, since the flux is proportional to O I, we have S I is proportional to $s \times O I$, or $\frac{S I}{O I}$ is proportional to $s$, where $s$ stands for the speed of the motor. This construction for the speed may easily be simplified as follows: Draw a line S P, such that the angle O S P equals the angle S I O, and produce O I to meet it in P. The two triangles O S P and S I O will now be similar, since the angle O S P equals the angle S I O, and the angle S O I is common. Therefore $\frac{P S}{O S} = \frac{S I}{O I'}$, and since O S is constant, the speed must be proportional to S P. Moreover, since O S P = S I O = S O F, as shown above, S P must be perpendicular to that diameter of the circle which passes through the origin. The torque, of course, is proportional to $(O I)^2$. Since output = torque × speed, we have output $= \frac{S I}{O I} \times (O I)^2 = S I . O I$. The following reductions of the torque and output constructions to a linear form I take from Blondel's paper on the series motor in *L'Eclairage Electrique* last year.

Since the angle S I O is constant, the product S I . O I is proportional to the area of the triangle S I O, which is simply proportional to its altitude, I H, since the base, O S, is constant. Thus we see that the output corresponding to any current may be represented by an ordinate I H drawn from the point I perpendicular to the standstill current. Also, since in a circle $(O I)^2 = O M . O N$* where O M is the diameter through O, and O N is the projection of O I on it, we see that the torque is proportional to O N, since O M is constant. Since we have output = I H, and, obviously, input = I R, we have efficiency = $\frac{I H}{I R}$. This may easily be reduced to a linear form as follows: Draw a circle (see Fig. 3) equal in size to the current circle, and with its centre, C, a fixed distance, measured along a line parallel to I R, below that of the current circle. This circle will cut off from I R a distance, I A, equal to the distance between the centres of the circles. Draw through A a line parallel to H R, cutting I H in B. Then $\frac{I B}{I A} = \frac{I H}{I R}$, and as I A is constant, I B measures the efficiency. Now, the locus of B, as the speed varies, is very nearly a circle, there being one circle for every position of C.† This can easily be verified by trial.

Every such circle will pass through the point S, and be tangent to a line drawn perpendicular to O S, and touching the current circle at a point near the origin. These conditions enable us to draw in a suitable circle at once on our diagram. It will be proved below that O D (Fig. 3) represents 100 per cent. efficiency. This gives us the scale of the construction (approximately). Thus the efficiency is measured simply by the intercept between the current circle and the efficiency circle of a line drawn through I perpendicular to O S. It may be seen that the efficiency continually rises from standstill to infinite speed, so that when the power factor is good the efficiency will be good also. Moreover, from the construction for the output it can be seen that when the power factor is good, the output, though past its maximum, is still large. These facts form the reasons why the series motor is so much superior to some other single-phase motors, such as the repulsion motor, in which, as the circle diagram shows, it is very difficult to get good power factor concurrently with good efficiency. It should be noted that the efficiency used above is the electrical efficiency, account being taken only of those losses proportional to the square of the current, such as the eddy-current loss—in this discussion the loss by the short-circuit current under the brushes‡ is considered as an eddy loss—the resistance loss, and (roughly) the hysteresis loss due to the alternation of the flux. No account is taken of the hysteresis loss due to the rotation of the armature or of the friction and windage.

A diagram, similar in many respects to the above, which allows of a very interesting comparison between the two motors, may easily be deduced for the direct-current series motor. At standstill a current O S = $\frac{e_0}{r}$, if $e_0$ be the impressed E.M.F. and $r$ the resistance of the motor, will flow through the circuit, the impressed E.M.F. being balanced by the resistance drop. Consequently, if another E.M.F., such as the counter E.M.F., $e_1$, of the motor, be applied, a further current S I = $\frac{e_1}{r}$ will flow in opposition to the current O S. Thus as the motor speeds up the point I moves from S

* A proof of this proposition will be given in Appendix I. The geometrical proof is as follows:

We know that $(I N)^2 = O N . N M$. Add to both sides $(O N)^2$. Then $I N^2 + O N^2 = O I^2 = O N (O N + N M)$;

$$\therefore O I^2 = O M . O N.$$

† The accuracy of this construction is discussed in Appendix II.

‡ This current is the principal cause of the phase difference between the current and the back E.M.F.

Digitized by Google

towards O, along the straight line O S (see Fig. 2*a*). For the same reasons as in the alternating-current motor, the speed is proportional to $\frac{S\,I}{O\,I}$, and the torque to $O\,I^2$. We also have efficiency $= \frac{e_1}{e_0} = \frac{S\,I \times r}{O\,S \times r} = \frac{S\,I}{O\,S}$, which becomes unity or 100 per cent. at infinite speed when S I = O S. As in the alternating-current motor, the output is a maximum when $S\,I = O\,I = \frac{1}{2}O\,S$. Thus we arrive at the well-known proposition that when the output of a direct-current motor is a maximum its efficiency is 50 per cent.

A similar investigation in the case of the alternating-current motor gives much more favourable results. In this motor the only E.M.F.'s in phase with the current are $i\,r$, the drop caused by the various resistances of the motor, and $e_1 \cos\theta$, a component of the counter E.M.F.; $\theta$ will usually be so small that it can be neglected. Thus we can express the input in the form $i\,(e_1 \cos\theta + i\,r)$, since the above are the only E.M.F.'s that consume power. Now, since $i^2\,r$ represents all the losses that we can take into account (see above), $i\,e_1 \cos\theta$ must be the output. Thus, as in the direct-current motor and in the synchronous motor, we have output = current × projection of counter E.M.F. upon it. Indeed, a proposition similar to this may be proved for any motor. Thus we get

$$\text{Efficiency} = \frac{e_1\,i\cos\theta}{e_0\,i\cos\phi} = \frac{e_1\cos\theta}{e_0\cos\phi} \quad . \quad . \quad . \quad (1)$$

where $\cos\phi$ is the power factor. Moreover, if $z$ be the total impedance of the motor, we have $e_1 = S\,I \times z$ and $e_0 = O\,S \times z$, and therefore efficiency $= \frac{S\,I\cos\theta}{O\,S\cos\phi}$. Thus, when the output is a maximum, the efficiency will be much greater than 50 per cent., because, owing to the phase

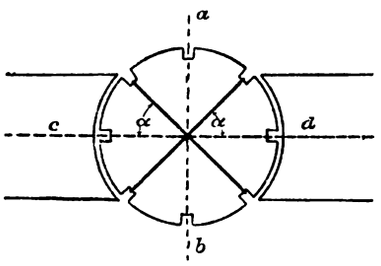

FIG. 4.

difference between the current and the E.M.F., the power consumed will be much less than that consumed in the direct-current motor under similar conditions. At infinite speed, since $\theta = \phi$ and S I = O S, we get 100 per cent. efficiency, as in the direct-current motor. This, as was pointed out above, is the electrical efficiency only.

The fact that the efficiency is 100 per cent. at infinite speed serves to fix approximately the scale to which the constructions given above measure the efficiency and output; and also, if we know the speed scale, it will give us the torque scale. The values thus obtained, however, will be a little too high, for the reason mentioned above. Thus we arrive at the conclusion that by working well beyond the top of the circle in Fig. 2 we can get good power factor, high efficiency, and good "weight efficiency." The next question which arises is how to design the motor so as to attain this end.

In the following investigation, the resistance of the motor and the small angle $\theta$ between the counter E.M.F. and the current will be neglected. Let

$n$ = number of turns on the field.

$n_1$ = " " " armature between brushes. Thus $4\,n_1$ will be the number of conductors on the armature.

$s$ = speed in revolutions per second.

$p$ = permeance of main magnetic circuit, or, in other words, the number of lines produced in it per ampere-turn. If there are more than one pair of poles, $p$ will be the sum of the permeances of all the magnetic circuits in parallel.

$p_1$ = permeance of the armature magnetic circuit.

$\nu$ = leakage coefficient.

$f$ = frequency of supply in cycles per second.

Now, if we are to have good power factor, etc., we must make the ratio $\frac{S\,I}{O\,I}$ (Fig. 2) large. Now, S I is the current produced by the counter E.M.F.,

$$\therefore S\,I = \frac{\text{counter E.M.F}}{\text{impedance}} = \frac{4 \times O\,I \times n\,p \times n_1 \times s}{2\,\pi\,f\,(n^2\,p\,\nu + n_1^2\left(\frac{2}{\pi}\right)^2 p_1)} \quad (2)$$

as the counter E.M.F. is obviously given by the same formula as in a direct-current machine.*

The reactance of the field is obviously given by the expression $2\,\pi\,f\,n^2\,p\,\nu\,10^{-8}$, since $n^2\,p\,\nu\,10^{-8} = L$, the coefficient of self-induction; but on account of the fact that the armature winding is not on a bobbin, as is the field, somewhat greater care is necessary in determining its reactance. Let $a\,b$ (Fig. 4) be the line of the brushes, and $c\,d$ a line perpendicular to it. If we consider two turns, each making an angle $\alpha$ with $c\,d$, one on each side of the brush line, we see that the magnetising force in the direction $c\,d$ due to one turn is exactly balanced by that due to the other. In the direction $a\,b$, however, the magnetising force of the two turns will be added. Since half the main current flows through each turn, the pair produce, in the direction $a\,b$, $i \sin\alpha$ ampere-turns, where $i$ is the current through the brushes. If for the sake of simplicity we suppose the winding evenly distributed, the ampere-turns produced by the whole armature will be

$$i\,n_1 \frac{1}{\pi}\int_{-\alpha}^{\alpha} \sin\alpha\,d\,\alpha = \frac{2}{\pi}\,i\,n_1.$$

Thus only $\frac{2}{\pi}\,n_1$ of the armature turns can be said to be active, and the reactance is therefore $2\,\pi\,f\left(\frac{2}{\pi}\,n_1\right)^2 p_1$, or $0{\cdot}405 \times 2\,\pi\,f\,n_1^2\,p_1$.

Thus we see that $\frac{S\,I}{O\,I}$ is increased by: (1) Raising the speed, if allowable. (2) Lowering the frequency. It will, as a rule, be much easier to design a satisfactory series motor for low frequencies than for high, though I believe it can be done for any frequency not much exceeding 50. (3) By suitably designing the winding.

The expression for $\frac{S\,I}{O\,I}$ above will have a maximum for a definite value of $n$ if we regard $n_1$ as constant. Differentiating with regard to $n$, equating to zero, and solving the equation thus formed, we get

$$n = \frac{2}{\pi}\,n_1\sqrt{\frac{p_1}{p\nu}} \quad . \quad . \quad . \quad . \quad . \quad (3)$$

Substituting in (2) we get

$$\frac{S\,I}{O\,I} = \frac{4\,n_1^2\sqrt{\frac{p_1\,p}{\nu}}\,\frac{2}{\pi}\,s}{2\,\pi\,f\left(\left(\frac{2}{\pi}\right)^2 n_1^2\,p_1 + \left(\frac{2}{\pi}\right)^2 n_1^2\,p_1\right)} = \frac{s}{2f}\sqrt{\frac{p}{\nu\,p_1}} \quad (3A)$$

This expression obviously increases indefinitely with the decrease of $p_1$, and is independent of the number of turns on the armature. We also see that the maximum value of $\frac{S\,I}{O\,I}$ occurs when the field impedance is equal to the armature impedance. Thus it is very important to make the permeance in the path of the armature flux as small as possible. The permeance of the main circuit should, as usual, be made as great as possible and the magnetic leakage as small as possible. It is in order to make $p_1$ small that the alternating-current series motor is made with salient poles, like a direct-current machine, instead of being wound like an induction motor.

If the speed of the motor and the number of turns on the armature are constant, the counter E.M.F. will be proportional to the ampere-turns on the field alone. Since

* By taking $p$ as constant, we are, of course, assuming that the iron is worked well below saturation, which is necessarily the case in alternating-current machines. $\frac{S\,I}{O\,I} = \cot\phi$ if we neglect resistance.

Digitized by Google

it is in phase with the current we may compare it to the resistance drop in the field, which is also proportional to the product of the current into the number of field-turns (if the same size of wire is used throughout). This point of view enables us to consider the effect of varying the number of turns on the field in a very simple way. Let $r_0$ be the "resistance" per turn $= 4\,p\,n_1\,s\,10^{-8}$. Then

$$\text{Efficiency} = \frac{i^2\,n\,r_0}{i^2\,(r + n\,(r_0 + r_1))}$$

where $r + n\,r_1$ is the total equivalent resistance of the motor and $r_1$ is the resistance of one turn of the field. Cancelling out $i^2$, dividing by $n$, and putting $n = \infty$ we get

$$\text{Efficiency} = \frac{r_0}{r_0 + r_1},$$

Thus we see that as the number of field-turns increases the efficiency at a given speed rises continuously.

The above investigations regarding power factor and efficiency become much clearer when regarded from a geometrical point of view (see Fig. 15), as is done in Appendix I.

### Design of the Series Motor.

In designing a series motor the following information will generally be given:

| | |
|---|---|
| Output at full load... | $= W$ watts |
| Speed ..... | $= s$ revolutions per second |
| Power factor to be not less than | $\cos \phi$ |
| Overall efficiency ... | $\eta$ |
| Impressed E.M.F. ... | $= e_0$ |
| Frequency ..... | $= f$. |

Let us first consider the design of a winding for a given carcase. We must first find the current at full load:

$$i = \frac{W}{e_0\,\eta\,\cos\phi}$$

Next we must find the counter E.M.F. For the present purpose we may neglect the small phase angle between current and counter E.M.F. We then have from equation (1)

$$\text{Electrical efficiency} = \frac{e_1}{e_0\,\cos\phi}.$$

This serves to determine $e_1$. The electrical efficiency must, of course, be estimated from experience. It should be possible to take account of a large part of the iron losses in it, but if this proves impossible they must be estimated in the usual way. With this exception, those losses which are not taken account of in the electrical efficiency will be much the same as in direct-current machines, and thus experience gained with these would apply in estimating them. We now have

$$e_1 = \frac{4\,n_1\,s\,i\,n\,p}{10^8}, \text{ or } n\,n_1 = \frac{e_1\,10^8}{4\,s\,i\,p} \quad . \quad . \quad (4)$$

Since the magnitude and phase of $e_1$ are known, we can compound it with $e_0$ graphically, and find the E.M.F., $e_2$, which actually causes the current to flow. Now,

$e_2 = i\,z$ or $\frac{e_2}{i} = z$, where $z$ is the total impedance of the motor.

Neglecting, for a first approximation, the resistance of the motor, we have

$$\frac{e_2}{i} = 2\,\pi\,f\left(p\,\nu\,n^2 + \left(\frac{2}{\pi}\right)^2 p_1\,n_1^2\right)10^{-8} \quad . \quad . \quad (5)$$

since $p\,\nu\,n^2\,10^{-8}$ is the coefficient of self-induction of the field and $\left(\frac{2}{\pi}\right)^2 p_1\,n_1^2\,10^{-8}$ that of the armature, as considered before. From this equation, together with the one above, $n$ and $n_1$ may be calculated.

Solving these two equations, we get

$$4\,\pi\,f\,p\,\nu\,10^{-8}\,n^2 = \frac{e_2}{i} + \sqrt{\left(\frac{e_2}{i}\right)^2 - \frac{p_1\,\nu}{p}\left(\frac{e_1}{i\,s}\right)^2 f^2}$$

and

$$4\,\pi\,f\left(\frac{2}{\pi}\right)^2 p_1\,10^{-8}\,n_1^2 = \frac{e_2}{i} - \sqrt{\left(\frac{e_2}{i}\right)^2 - \frac{p_1\,\nu}{p}\left(\frac{e_1}{i\,s}\right)^2 f^2},$$

two formulæ which are not so formidable as they look. It should be noticed that it will not be possible to fulfil the conditions given by equations (4) and (5) for all values of W, $\eta$, and $\cos\phi$. For instance, from equation (3A) we see that there is a maximum value of $\frac{S\,I}{O\,I}$, and therefore of $\cos\phi$, which is independent of $n$ and $n_1$. If we assume $\cos\phi$ greater than this, equations (4) and (5) will give imaginary value of $n$ and $n_1$. Having roughed out the design in this manner, we may now check back, and introduce corrections, to take into account the resistance, etc.

We may, however, if we choose, take the resistance into account from the beginning. Although in a large machine this may not be necessary, in a small one it will be more important. In order to take the resistance into account, all that we need do is to substitute the expression $\sqrt{\left(\frac{e_2}{i}\right)^2 - r^2}$ (where $r$ is the total effective resistance of the motor) for $\frac{e_2}{i}$ in equation (5), and all succeeding equations. We may easily determine $r$ from the equation

$$r = \frac{\text{input} - \text{electrical output}}{(\text{current})^2} = \frac{W\,(1 - \eta_1)}{\eta\,i^2},$$

$\eta_1$ being the electrical efficiency, and $\eta$ the overall efficiency. These formulæ furnish us with all that is necessary for designing a winding for a given carcase.

If, however, the carcase as well is to be designed, we must, of course, proceed differently. Having worked out the full load current and the counter E.M.F. as above, the next thing to do appears to be to settle tentatively the number of armature turns. In doing this three considerations must be taken into account: (1) the counter E.M.F. required, (2) the impedance of the armature, (3) the commutation of the motor.

It will be found that unless a very large and massive field magnet be employed, and also a very small air-gap, that it is practically impossible to obtain a strong flux. Thus, in order to get the required counter E.M.F., it will, in almost all cases, be necessary to use a large number of turns on the armature. It is important to notice that for a given current and given flux through a coil, far more E.M.F. will be induced in it, if the magnetic circuit has a low permeance, than if it has a high one. The reason of this is that we shall require a larger number of turns in the former case, and shall therefore get a larger E.M.F. of self-induction since this E.M.F. is proportional to the square of the number of turns in a coil, while the flux through it is proportional to the first power only. Thus we see the importance of making $p$ the permeance of the main magnetic circuit as large as possible. On account of the large number of armature turns which will, as a rule, be necessary, the impedance of the armature will be very considerable, unless we take very special precautions to reduce $p_1$, the permeance of the armature magnetic circuit, by thoroughly slotting the poles, and by using compensating coils. The best way to convince oneself of the importance of doing this is to work through an example or two, such as the one given below.

With a little previous experience of a similar machine it would be easy to settle approximately the number of turns on the armature without much risk of error. Without this, however, all one can do is to work through various designs until one gets a satisfactory one. The considerations mentioned above may serve to some extent as a guide. Having settled the number of armature turns, we can find $n\,p$ from equation (4) and then $n$ and $p$ from equation (5).

It is of considerable interest to compare briefly the design of the alternating-current and of the direct-current series motor. In both machines the number of armature turns determines the flux, and the dimensions of the field magnet, the number of turns which will be required on it in order to give this flux. In the alternating-current motor, as soon as we have determined these quantities, we have practically determined the impedance of the machine as well, according to equation (5). The resistance of the direct-current motor, on the other hand, is not determined by the numbers of turns on the field and armature, since it may be given any value, by putting sufficient copper on the machine.

Digitized by Google

Thus we see that in the alternating-current motor, since the impedance is determined by the number of field and armature turns, there are not so many independent variables as in the direct-current machine, and consequently the limits of good design are much narrower. With regard to the design of a carcase, I am at present unable to say much, since there was only one carcase at my disposal, and I was compelled to conduct all my experiments on that. The weak point of the above method of design, when we come to apply it to the design of a complete motor, is clearly the absence of any method of determining the self-induction of the armature from its dimensions. To calculate this self-induction rigorously seems impossible, and we must therefore have recourse to approximate formulæ of the same nature as those of Behrend and Behn-Eschenburg for the "dispersion coefficient" of the induction motor. To obtain such a formula it is obviously necessary to test many different machines. For instance, instead of the $\left(\frac{2}{\pi}\right)^2 p_1$ used in equations 2, 3, 3A, and 5, which is only the roughest of approximations, we should use an expression which will be a function of the air-gap, pole-pitch, shape and number of slots, etc., and should also express the effect of the compensating coils. The reluctance, and hence the self-induction, of the field, and the leakage coefficient, can easily be calculated by the well-known rules.

*Example of the Design of an Alternating Current Series Motor.*—In order to illustrate the method of design given above, I reproduce a design for rewinding the motor used in the experiments described below. On account of the unsuitability of the carcase, however, it is impossible to obtain very good results even at such a low frequency as 25. Specification:

| | |
|---|---|
| Output at full load ..... | = 1 kw. |
| Speed ..... | = 2,000 r.p.m. |
| Power factor ..... | = 0·75 |
| Electrical efficiency ..... | = 70 per cent. |
| Impressed E.M.F. ..... | = 100 volts |
| Frequency ..... | = 25 |

$$i = \frac{1{,}000}{100 \times 0{\cdot}75 \times 0{\cdot}7} = 19 \text{ amperes.}$$

$$0{\cdot}7 = \frac{e_1}{75}, \text{ therefore } e_1 = 52{\cdot}5 \text{ volts.}$$

Compounding $e_1$ with $e_0$, we get $e_2 = 64$ volts. (It must be remembered that $e_1$ is *opposite* in phase to the current.)

$\therefore \frac{e_2}{i} = 3{\cdot}37$ ohms, the permissible impedance of the motor.

As a mean of several sets of experiments on the carcase to be rewound, we obtain $p = 290$ so long as the magnetic circuit remains unsaturated, and

$$\left(\frac{2}{\pi}\right)^2 p_1 = 60.$$

$\nu$ is practically equal to 1·24. Thus we get

$$n\, n_1 = \frac{52{\cdot}5 \times 10^8}{4 \times 33{\cdot}3 \times 19 \times 290} = 7{,}180 \text{ (about),}$$

and $$3{\cdot}37 = 157\,(360\, n^2 + 60\, n_1^2)\, 10^{-8}.$$

Since there are 36 slots on the armature, we are obliged to choose some value for $4\, n_1$, the number of conductors on the armature, which is divisible by 36. The most suitable value appears to be 504, which gives

$$n = 56, \text{ and } n_1 = 126.$$

These values will be found to satisfy approximately the above equations. These values give

| | |
|---|---|
| Field reactance..... | = 1·75 ohms. |
| Armature reactance..... | = 1·49 ohms. |
| Total reactance of motor | = 3·24 ohms. |

Since the armature impedance is nearly equal to the field impedance, we see that the power factor is almost the best possible.

*(To be continued.)*

## READING ELECTRICAL EXHIBITION.

The electrical exhibition organised by the Reading Electric Supply Company, Limited, under the able management of Mr. A. T. Cooper, the engineer of the company, was opened on Monday at noon by the Mayor of Reading (Mr. Sutton).

The exhibition is held in buildings adjoining the generating station, which for the week is thrown open for inspection to the visitors. The plant consists of high-speed engines driving tandem continuous-current generators supplying current to the central portion of the town on the three-wire system, while the outlying districts are supplied with high-tension alternating current. One of the features of the station is the new gas-producer plant now in the course of erection, which is to supply gas to two slow-speed 750-b h.p. gas-engines made by Messrs. Willans and Robinson driving Siemens continuous-current generators, which will when completed take up the steady load, the existing plant taking the peak and light loads, the gas-engines under these conditions working at their most economical point, which will enable the company to reduce their rates of supply.

The local firms were well represented, as well as several from London, the exhibits consisting principally of fittings, lighting and heating appliances, and practical applications of electric driving to printing, wood-working, ice and bread-making machinery. Prominent amongst the local exhibitors is Mr. S. Griffith, of the Railway Foundry and Engineering Works, Reading, who exhibits the manufactures of his electrical department, managed by Messrs. Griffith and Biliotti, of 8, John-street, Adelphi. The machinery on this stand consists of continuous-current motors, ranging from 2½ h.p. to 25 h.p., which are seen at work. The 25-h.p. motor drives a 20-kw. generator supplying current to various polyphase motors. These motors are particularly noticeable for their substantial and compact design and excellent performance. One of these motors fixed on the ceiling drives a drilling machine, a special manufacture of the firm which will drill a ⅜in. hole through 1in. cast-iron plate in 20 seconds, and which by a very convenient arrangement allows holes to be readily drilled at any angle.

Another novelty is an electric clock which is arranged to ring a number of bells in different shops at the times of starting and stopping of work, and does not ring during the night. In addition to the above, there are a number of time element cut-outs, two of them shown at work on a two-phase motor circuit set to act within 7½ minutes with 50 per cent. overload. Two other types are also shown, one of them for quick action, specially suitable for feeders acting within 90 seconds with 50 per cent. overload, and in 30 seconds with 100 per cent. overload, the other for slow action working within half an hour with 50 per cent. overload.

The above firm has also a good show of Messrs. Johnson and Phillips's instruments and cables, for which they are sole agents for the district.

Another interesting exhibit is that of the Industrial Storage Battery Syndicate, showing the Elieson patent accumulator in various stages of manufacture. This accumulator, specially suitable for electric cars, can be charged to its full capacity within half an hour or an hour, and discharged at the same rate without injury. The exhibition, which will be open till Saturday next, was well attended during the opening days, and has every prospect of being a success.

## CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

### ELECTRIC PUMPING.

SIR,—I should like to correct a statement which appeared in my reply to Question 770, April 21. The maximum speed of the pump is given as five revolutions per minute, which obviously corresponds to five double strokes, or half the maximum number specified in the question.

London, W., April 23, 1905. E. AUSTIN.

## SINGLE-PHASE TRACTION.

We are pleased that the Institution of Electrical Engineers have under discussion the question of the use of single-phase alternate-current motors for traction purposes. The matter is one which brings out most clearly the international character of the competition in electrical engineering. The discussion which took place at St. Louis last autumn on Mr. Bion J. Arnold's address on this problem was most interesting, although somewhat general in character, and more detailed information may now be available. In fact, this is a fault which is common to most of the information given on this important subject. This charge cannot be brought against Mr. F. Creedy's paper on the alternating-current series motor, which was discussed last night with Mr. Arnold's address. In this full details are given of an interesting experiment on a motor which, although small, enabled the author's theories to be investigated and proved. The information is hence the more valuable as the whole truth is given, as cannot be the case with the information published by commercial firms, who have to depend for their profits on the superiority of their machinery over those of their rivals. Reverting to the development of the single-phase motor, this was largely due to the success of the Swiss and other Continental firms in the adaption of the three-phase induction motor for railway working. On railways through mountainous districts these induction motors give great satisfaction, and led other engineering firms to push forward their experimental work which had for its object the design of a rival system more applicable for ordinary railway working. The work carried out in connection with single-phase traction has been mostly done by American and Continental firms. The magnitude of the experiments makes the cost almost prohibitive except in the case of large manufacturers, who can afford to devote considerable sums on the development of new specialities. The results obtained on both sides of the Atlantic lead one to agree with Mr. R. G. Lamme in his statement before the St. Louis Convention—*i.e.*, that "The single-phase system is the one means presented at the present time as a solution of the heavy railway problem. It has all the advantages of the direct-current motor in the variable speed characteristics, and has also the advantage possessed by alternate current in the ability to use any line pressure desired and to vary the pressure applied to the motor, and thus vary the speed over any range desired. It has also the advantage of permitting a system of control that can be obtained without sparking." This last advantage refers to sparking at the controller and to the system by which a variable-ratio transformer in which the relative positions of the primary and secondary coils is altered to give any voltage on the motor without any step-by-step interruption in the circuit. The use of these single-phase motors for railway working is likely to be developed more quickly from the fact that so many firms are working on the problem independently. Thus, when tenders were asked for for the equipment of the trial line of the London and Brighton and South Coast Railway Company on this system to Mr. Philip Dawson's specification, the competition was almost as keen as if direct-current motors had been called for. Each of the firms who tendered have independently investigated the problems involved, and most of them have conducted trials with single-phase motors on a scale which is comparable with normal railway conditions. It seems likely, therefore, that in the future, for main-line working at least, the single-phase system will be adopted. It does not follow that there will be much change in the method of generating and distributing the energy required. Three-phase alternators

Digitized by Google

working at a frequency of twenty-five will still be applicable. All the alterations that will be necessary will be in the sub-stations. Here the static transformers now employed to feed the rotary converters can be replaced by others so connected as to convert the three-phase currents received into two-phase currents. One phase can then be used to supply the line in one direction, while the other will be connected to the overhead wires proceeding in the opposite direction. In this way the advantages of three-phase plant for generation and transmission can be retained, while single-phase current is employed on the line. The reductions in cost by the employment of a higher line voltage and the supersession of the rotary converter will make th conversion problem a much simpler one financially. It remains to be proved, however, that while the single-phase system greatly simplifies electrical running on main lines, it will also be able to compete with the direct-current motor on suburban branches or in tube railways, where the traffic is dense and the distance between stations such that the trains are always either accelerating or being braked. It is only fair to add that while this query seems a reasonable one with the information now before us, it must be remembered that we are comparing the results of a new type of motor with those from the series direct-current machines as perfected by years of trial. The newer types of single-phase motor after similar experience may be able to hold their own even when extremely rapid acceleration is required.

## UNSOLVED PROBLEMS IN ELECTRICAL ENGINEERING.*

BY COLONEL R. E. B. CROMPTON, C.B., M.I.C.E.

*(Concluded from page 562.)*

Whilst on the lighting question, I wish to mention a matter which has interested me, although it can only indirectly be called an electrical problem. Years ago I was fortunate enough to observe the following phenomenon. Whilst in a carefully closed tent with double top, and walls thick enough to exclude the faintest ray of the Indian sun, I, in the course of a severe thunderstorm, was able to distinguish minute details of the outside scenery by the walls being rendered practically transparent by intense flashes of lightning. Personally, I have no doubt of this, but the phenomenon appeared inexplicable, until it was suggested to me that the lightning flashes were so rich in violet short wave-length rays of low refrangibility that they were able to render transparent all substances which owe their opacity to the centrifugal refraction of the white or yellowish ray of sunlight. As in the Cooper Hewitt lamp we are now able to command rays of the right colour by condensing a beam of this blue light, we may hope to render transparent many vegetable substances, such as wood and similar materials, which have hitherto been considered completely opaque to ordinary vision.

A problem of real moment to both suppliers and users of electrical energy would be the discovery of a direct method of producing artificial cold by electrical means. If we had a ready means of producing artificial cold so as to obtain cold storage in our larders, and so preserve our perishable foods, vegetables, and fruit, it would obviously greatly add to the pleasure of our lives and to the economy of our housekeeping. Of course, we can now produce artificial cold by connecting an air-compressor to be driven by an electric motor, and by expanding the air into the cold storage chamber, but the method is costly and cumbrous. Probably something may be done by a well-designed high-speed air compressor, but the real solution we are looking forward to is a direct method of producing cold from the electrical energy in our supply mains, and this probably is a problem for the electro-chemist, as we may conceive the apparatus taking the form of a battery abstracting heat from the surrounding air.

The use of electricity for cleaning purposes has been considerably developed during the last year or two, as we are familiar with the vacuum cleaning apparatus, which in most cases is driven by an electric motor, but it ought to be within the power of the designer of electrical novelties to produce electrical cleaning apparatus of a simpler character which would be within the reach of all of us who have the electrical supply in our houses.

The recent experiments of Lodge in dispersing fog and collecting dust by communicating static charges to the atmosphere containing such particles deserves mention as worthy of further development.

The application of electricity to these domestic purposes will have the secondary effect of increasing the day load of our lighting companies, and will react by reducing the cost of electricity not only for these purposes, but for heating and for lighting, hence the importance of the problems involved.

A few years ago, when in India, the problem was put to me of pulling punkahs by electricity. Although I said it was a simple one I was challenged to make it good. Since that time the problem has nearly reached complete solution. Many secondary ones arose out of it, not the least being that as the slow-speed fans used were placed immediately overhead in living-rooms and bedrooms it was quite impossible to adopt any means of oiling on account of the danger of the oil dripping. The wonderful perfection recently obtained in ball bearings and in mechanical winding of armatures has enabled this problem to advance very closely to perfect solution; at any rate, I am told that since the introduction of the electrical fan, life in Calcutta during the hot weather has become far more tolerable than heretofore.

Time will not permit me to speak at any length on the interesting subject of electrical heating. At first our attention was directed to means by which our electrical energy could be used for the production of low temperatures, such as radiators for heating our rooms, boiling water, heating ovens, and similar domestic uses, and although the demand for this class of apparatus has up to the present not been great, owing to the cost of the energy being in most cases still too high, yet steady progress has been made, and in certain towns its use has been extended in a very encouraging manner; but there is another use for electric heating, and that is the production of much higher temperatures, such as those required by the chemist and metallurgist. The importance to the mechanical engineer, chemist, or physicist of being able to maintain in quite small furnaces extreme regularity of high temperature for very long periods of time cannot be over-estimated, and this problem is already satisfactorily solved; but when we deal with electrical furnaces on the larger scale, I may point out that although when Keller read his paper on electrical metallurgy before the Iron and Steel Institute in 1903, the possibility of electric smelting taking the place of heating direct by fuel was received with much incredulity, since that time so much attention has been given to the matter that this problem has already been successfully grappled with, and appreciable advances have been made in the practical application of electrical smelting. De Laval, Ross, and others have arrived at very concordant results, and already the Heroult furnace for the production of steel from scrap iron has been carried out on a commercial scale in France and in Sweden, and in both cases we are told that the high quality of steel thus obtained shows that the process is already a commercial success, and may be of great importance to those countries which possess water power, so that this direct process of electric smelting may be readily developed.

In discussing the past and future problems of the core and coil on which so much of the efficiency of our generating, transforming, and utilising apparatus depends; again, in discussing the problems of storage, of the electrical driving of our railways, and of the further utilisation of electrical energy for the needs of our daily life, I have been more struck with the extreme difficulty I feel in confining myself to matters which have been hitherto considered strictly electrical ones. I am sure all my brother engineers will feel with me that the necessities of our profession compel us to take up and study the far wider field of knowledge of general engineering. The power engineer is called

* The "James Forrest" lecture, 1905, delivered before the Institution of Civil Engineers.

Digitized by Google

upon—at all events, in this country—to deal with the problems of fuel and water supply, the use of steam, or the internal-combustion engine, and the whole range of subjects connected with the properties and strength of materials, and of the methods of manipulating them, which to many are considered purely the province of the mechanical engineer. We claim that already we have profoundly influenced that profession. Our requirements have already modified the boilers, have practically given to the world the modern high-speed steam-engine, the steam-turbine, and have been a predominating influence in developing the internal-combustion engine. For instance, in the work we are now carrying on in standardising the electrical apparatus we use so as to facilitate the manufacture and interchangeability of parts, we find electrical requirements are already so predominant that they greatly influence the requirements of other uses of mechanical apparatus.

Finally, I believe the greatest problem of all, and the one which will have the most profound influence on the well-being of our fellows, is the satisfactory development of our power schemes by which we hope to send the population back to the land. Power distribution schemes of various degrees of magnitude have already been started in many countries. In those where water power was available they have made considerable progress, but in this country, where we have to look to the generation of our power from fuel, the series of problems involved are of the highest interest, are extremely hopeful of speedy solution, and the social consequences that will follow on them are likely to be so important to the health and better development of our race that they deserve the most careful consideration of our best men.

We already see that the necessity for bringing our working population into huge factories so that they may work within the range of power allowed by revolving shafting is already at an end; that nearly all power can be supplied through electric motors, and therefore the factory units themselves can be small, spaced more widely apart, and many classes of manufacturing processes can be carried out most perfectly in the worker's own home unaided by the other members of his family.

Already in Switzerland, France, and Germany, trades are being profitably carried on under conditions very closely approaching those that have been foreshadowed to us by the promoters of garden cities. A large proportion of our workers can carry on their business at home in a workshop attached to the dwelling-house, and separated from the neighbour by the garden in which the children can grow up under the best conditions of light, air, and sunshine. The electrical engineer who has been a chief cause in bringing about this vast social change will be honoured among those who have really benefited mankind.

I hope my audience will sympathise with me in my difficulties in dealing at all adequately with this interesting subject, which really calls for a course of lectures. My choice lay between giving you a mere list of the electrical problems which are still unsolved or of treating a few in the manner I have attempted, and which I fear is wholly unsatisfactory.

In one sense the preparation of this lecture has been to me a source of keen pleasure. My correspondence with my scientific and electrical friends, not only in England, but in France and America, has made me feel quite certain that one electrical problem is already thoroughly and completely solved—that is, the kindness, sympathy, and help that we electrical engineers can count on from one another. I hope those of my friends who have helped me by advice and information will understand when they hear or read this lecture that their assistance has been appreciated at its full value.

## APPOINTMENTS VACANT.

**Foreman** of switch and controller department. See advertisement in last issue.

**Switchboard Attendant**, Swindon Corporation electricity and tramways department. Wages 25s. per week. Applications by May 3. See advertisement in last issue.

**Borough Electrical Engineer and Tramways Manager**, Southend Town Council. Salary £400 per annum.

## RECENT TYPES OF AMERICAN ELECTRIC BLUE PRINTING MACHINES.

BY FRANK C. PERKINS.

A great step in advance in the making of blue prints is the application of electric arc lights and motor-driven

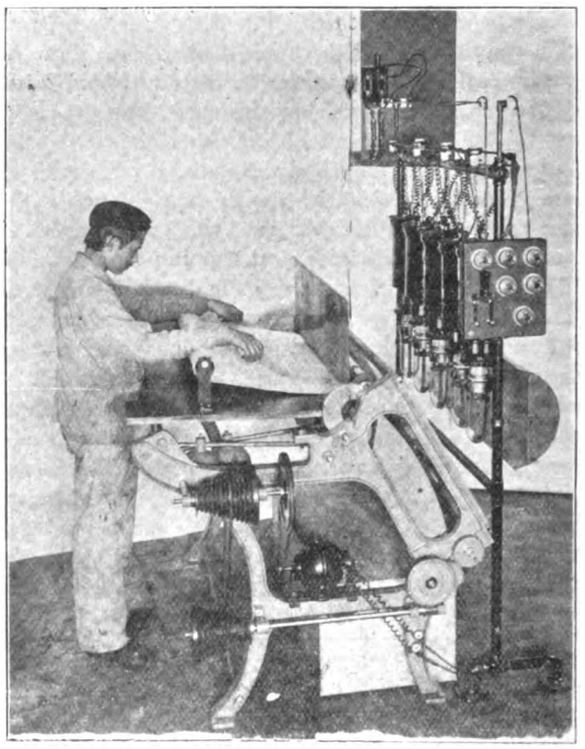

FIG. 1.—Franklin Electric Blue Printing Machine.

machinery, as it permits the production of prints made upon completion of the tracings, and the drafting-room is thus made entirely independent of weather conditions. The electric blue printing machines produce copies of uniform colour, and they have the advantage of making a continuous print of almost any length desired.

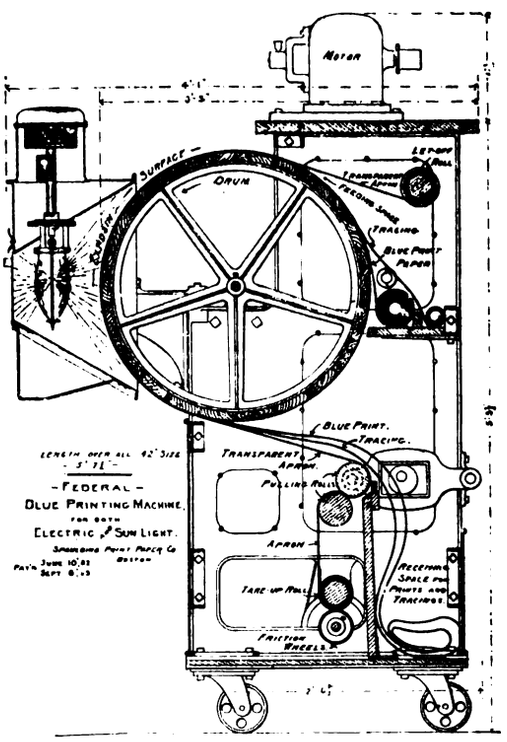

FIG. 2.—Drawing of Federal Blue Printing Machine.

The accompanying illustration (Fig. 1) shows the method of operation of the Franklin electric blue print machine, which has two continuous bands of transparent celluloid, which are held in position firmly by two rollers, one of which is the driving roller, which actuates the band, while

Digitized by Google

the other is an idler. The bands are caused to revolve synchronously, as the driving rollers are geared together and revolve at exactly the same rate of speed. As the transparent celluloid bands travel from one roller to another they pass over a convex surface shaped in a section of a cylinder, and are held by an automatic adjustable tension device in absolute contact with this surface and one another.

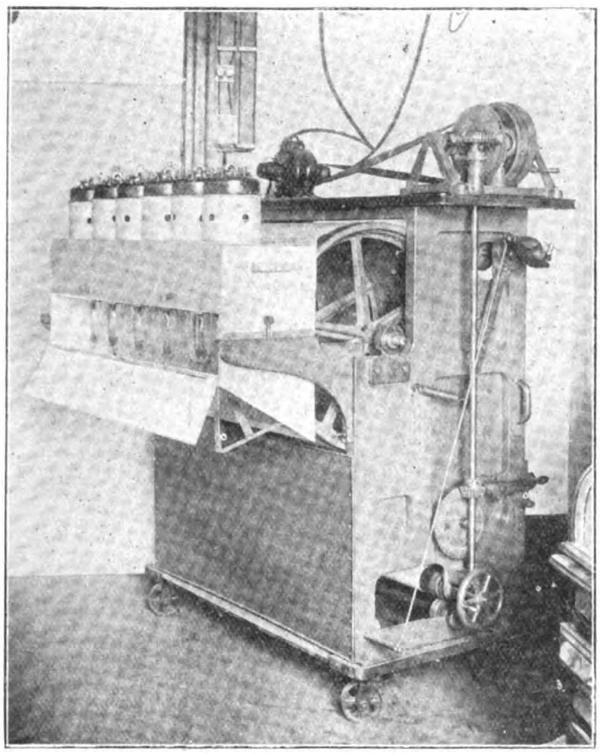

FIG. 3.—The Exposure Side of the Federal Machine, showing Arc Lamps.

The motor is of $\frac{1}{10}$ h.p. capacity, operated on a current of 104 volts or 220 volts, and the four or five enclosed arc lamps are employed, each taking a current of $2\frac{1}{2}$ amperes at 220 volts or five amperes at 110 volts. The speed of the motor may be varied by a cone device or by rheostat,

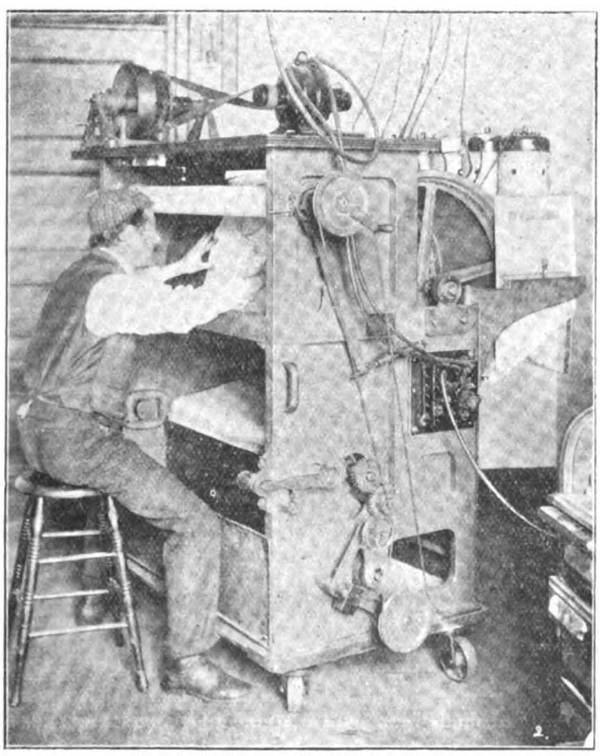

FIG. 4.—Federal Blue Printing Machine.

and in this way the bands may be operated at a slow or rapid speed, so that the tracings and sensitised paper may pass across the convex surface with a long or short exposure. The sensitised paper and the tracings are introduced between the transparent bands, which hold them in absolute contact as they pass in front of the electric lamp. It will thus be noticed that the printing is automatic in its operation and continuous as well, printing a long strip or making a number of prints from the same tracing in rapid succession. Prints may be made at a maximum speed of one minute exposure, or a minimum speed of 10 minutes, giving a wide range for all kinds of sensitised paper.

The drawing (Fig. 2) and illustrations (Figs. 3 and 4) show the construction of the "Federal" electric blue printing machine, which consists essentially of a drum revolving freely in roller bearings; a feed or let-off roll above the drum, and carrying a long, transparent, flexible apron; as well as a pair of pulling rolls under the drum and connected to the power through a speed-controlling mechanism. The transparent apron is drawn from the feed roll against a tension device around the surface of the drum, surrounding the latter about half of its circumference. The transparent apron, which is in contact with the surface of the drum, constitutes the exposing surface for printing. It will be noted that the blue print paper and the tracings are fed between the apron and the surface of the drum at the top of the machine, being carried around as the drum revolves, and are exposed to the action of electric light and then dropped automatically into a box below provided for the purpose. A roll of tracing cloth is used as a transparent apron, and this is wound upon the let-off roll, passing around the periphery of the drum to two pulling rolls, and then to a take-up roll, which winds it up automatically as fast as used. As soon as its entire length has been drawn around through the machine it is rewound ready for another run of exposure. It is claimed that the tracing cloth, when in close contact with the work, will transmit the rays of light in nearly the same time as plate glass. The ordinary roll is about 24 yards long and 42in. wide, and with this size six arc lamps are employed, each taking five amperes, and burning 130 hours continuously. With machines for printing copies 54in. in width, seven or eight electric lamps are employed. A small electric motor of $\frac{1}{4}$ h.p. capacity is used for operating this machine, and is mounted on the top of the machine and belted to a speed controller. Exposures are made either on a continuous roll of blue print paper or on separate sheets. When the continuous roll is used, the end of the paper is started under the transparent apron on the upper side of the drum, and the tracings placed one after another upon it as the drum revolves.

## ELECTRIC LIGHTING AND AIR-PUMPING ENGINE.

Through the courtesy of Mr. F. W. Baylis, the chief officer of the Manchester fire department, we are able to give the following particulars of a new engine recently bought by the department. The object of this engine, with its numerous equipments, is to enable firemen to adequately deal with fires in which large volumes of smoke are given off. In such cases the difficulty of approaching the source of the fire and of seeing in the smoky atmosphere have greatly handicapped the efforts of all fire brigades. The new engine, which has been supplied with all its accessories by Messrs. Merryweather and Sons, Limited, of Greenwich-road, London, S.E, enables the fireman to take light and air with him in such cases. The illustration which we give herewith shows that this engine is modelled after the firm's well-known fire-engines. It has the same type of water-tube boiler which enables steam to be quickly raised. This boiler supplies a vertical single-cylinder engine. The air-pump used to supply air to the helmets worn by the firemen is driven from the crankshaft of the engine. There is, however, a coupling inserted, by which the air-pump can be thrown out of gear if need be. This engine also drives, by means of a belt, a small dynamo which is placed on the fore-carriage to supply the hand lamps which are carried by the firemen when entering smoky buildings. It is capable of lighting eight lamps of 32 c.p. each. In order to regulate the voltage on these, a rheostat is provided in the shunt circuit of the dynamo. The six hand lamps used have each some 200ft. of insulated cable arranged on reels, so that it can be easily paid out

Digitized by Google

and wound up again. The air-hose used to supply fresh air to the helmets is carried on the drums shown in the illustration in 60ft. lengths. This hose is of the flexible metal type, and is used also as a conduit for the telephone conductors. Special couplings, with insulated contacts for the telephone circuit, are provided so that the lengths of hose can be quickly joined together. The most interesting feature, perhaps, of the equipment is the helmet itself. The earlier form is shown in Fig. 1, from which it will be seen that the helmets are provided with a leather mask which comes down over the firemen's shoulders. The air-hose was coupled at the back and the draught passing round the fireman's head tended to keep his eyes and nose clear of smoke. The air then passed out under the front of the mask. In the more recent types of helmet (illustrated in Figs. 2 and 3) the air connection is forked and supplies through two openings, one at either side of the helmet. It will be seen that a strap is provided to ensure a closer connection between the mask and the fireman's tunic. In this helmet also the front window is made to open, so that until the fireman enters the smoke he can breathe freely through this opening. The telephone receiver is fixed to one side of the mask, and the transmitter is in the front. As mentioned above, the wires for these telephones are led through the air-hose. The telephones are connected to an instrument on the engine itself, by means of which the officer in charge can keep in close touch with the fireman's requirements. With these helmets the men can enter buildings which would otherwise be inaccessible owing to smoke, and taking a strong light with them, they will be able to render a great service in locating the source of the fire. We understand that the engine and helmets have given satisfactory results on trial, but that up to the present the equipment has not been called upon for active service.

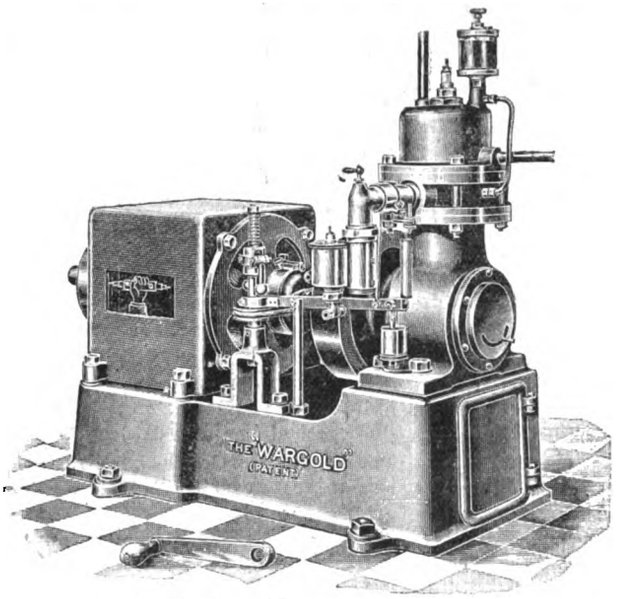
## TRADE NOTICES AND NOVELTIES

### Electric Lighting from Petrol.

The perfection of the petrol engine makes the combination of these prime movers with the dynamo an exceedingly portable one for electric lighting purposes. While such combinations were first introduced in connection with searchlight work in the army, they are becoming common for isolated installations where the number of lights required is small. Messrs. Ward and Goldstone, of Dutton-street, Strangeways, Manchester, are supplying a petrol engine connected to an enclosed type dynamo for such work.

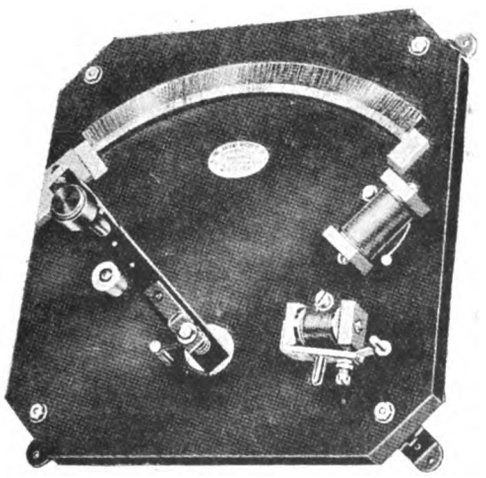


The Wargold Petrol-driven Dynamo.

The illustration herewith shows a combination capable of supplying 30 8-c.p. lamps at the same time. The engine is of the two-cycle type, giving an impulse at every revolution, which ensures an even turning moment. The makers calculate that with petrol at 9d. per gallon, the cost of fuel is equal to 1¼d. per horse-power hour, or, say, 2d. per unit. This type of plant will recommend itself to those owners of motorcars who wish to introduce electric lighting into country houses in inaccessible districts. The motorcar driver will then have no difficulty in supervising the running of the lighting plant.

### Improved Rheostats.

The Patent Rheostat Company, 18, Chapman-street, Hulme, Manchester, have sent us particulars of an improved form of starting rheostat which they are about to place on the market. In this rheostat the usual box of wire resistance coils is dispensed with, as also the contact studs, a patent contact resistance being substituted. This resistance is composed of thin sheet-metal stampings, packed into a channel in the slate base.



Front View of Motor Starter, showing Resistance mounted on the face of the Switch.

It is exposed upon the face of the switch, as shown in the accompanying illustration, and the contact lever makes contact directly with the resistance in the operation of switching on. Since the resistance is composed of a considerable number of segments, each of which represents a resistance unit, an ideal cutting-out arrangement is obtained, equivalent to that of a starter furnished with several hundreds of contact studs. Moreover, it enables a constant current increment to be maintained, and a motor to be consequently brought up to speed with perfect smoothness. For all uses the resistance is given a large cross-section, and is practically indestructible at proper current loads. It should be mentioned that the stampings of which the resistance is composed are of a non-rusting alloy. They are closely packed in the channel, and provision is made, by means of a spring inserted at the end of the resistance column, for expansion movements; also to ensure, with certainty, continuity in the resistance circuit. For the larger sizes of starters, where heavy currents have to be dealt with, two or more resistance columns are used in parallel, but all on the face of the switch, so as to obtain a large heat-dissipating surface. Special attention is drawn to the low price at which rheostats of the type in question can be manufactured.

### Accumulator Acid.

Messrs. F. W. Berk and Co., Limited, 1, Fenchurch-avenue, London, E.C., inform us that they have now registered their special accumulator acid as B. A. A. This acid is manufactured expressly for use in electrical batteries. It is made from the best Sicilian brimstone and distilled water, and is tested for chlorides, nitrates, lead, iron, and any other impurities before leaving the factory. Moreover, Messrs. Berk and Co., Limited, supply it in a concentrated form, or broken down to any degree of strength. We need not dwell here upon the importance of using suitable acid where electrical accumulators are concerned.

### Catalogues, etc., Received.

SIEMENS'S PUBLICATIONS.—Leaflet 560 just published by Messrs. Siemens Bros. and Co., Limited, York-mansion, York-street, Westminster, S.W., gives the outputs, weights, and dimensions of the firm's open-type G motors and new pattern G A motors, protected, ventilated-enclosed and fully-enclosed, the range being from 40 b.h.p. to 150 b.h.p. Specification 6A describes these G A motors.

ALTERNATING-CURRENT MOTORS.—List No. 4 (Section A) just issued by the Electrical Company, Limited, 121-125, Charing Cross-road, London, W.C., describes the firm's single, two, and three phase motors. These motors are of the semi-enclosed (protected), ventilated-enclosed, or totally-enclosed type, the windings and moving parts being well protected in all types from injury or accidental contact. They have been designed to meet the demand for motors occupying small space, of light weight, and possessing a large overload capacity, together with high efficiency, large starting torque, high power factor and low temperature rise. A special feature is the comparative small diameter of the rotor, in consequence of which its inertia is reduced to a minimum. Special consideration has also been given to the reduction of waste power by bearing and slip-ring friction, as well as to absolute safety to attendants with motors wound for high pressures.

D.C. VARIABLE-SPEED MOTORS.—Messrs. Vickers, Sons, and Maxim, Limited, River Don Works, Sheffield, have just issued section No. 2 of their new D.C. catalogue, containing prices and particulars of continuous-current variable-speed motors. The Vickers variable-speed motor is a specially constructed shunt machine, which will give on a single voltage the full power through a range of speed of 3 to 1, or even up to 6 to 1, if necessary, by shunt regulation. The motor runs with sparkless commutation at all speeds, and the efficiency is as high as that of an ordinary well-designed constant-speed motor. At the slow speed the starting torque is very high. Up to date upwards of 350 motors of this type have been made by the firm, in sizes from 2½ b.h.p. up to 90 b.h.p. The first of them were applied to a number of machine tools in 1897. Thus they have been thoroughly well tried.

## PERSONAL.

In view of his retirement on the 30th inst. as engineer and general manager of the Brighton Corporation tramways to take up the position as general manager to the Hastings and District Tramways Company, Mr. T. B. Holliday has been presented with a handsome silver bowl.

The Brighton Town Council have appointed Mr. Christie engineer and manager of the electricity undertaking in succession to Mr. Arthur Wright.

Mr. Lambert, the electric lighting engineer of Perth, has been appointed general manager of the electric tramways at a salary of £350, £75 of which is to be paid by the Tramway Committee.

We are asked to state that one of the directors of Messrs. Harris, Lee, and Co., Limited, Johannesburg, S.A. (Mr. H. M. Harris), will be in London at the beginning of next month, and can be seen by appointment at 165, Queen Victoria-street, E.C.

The Reason Manufacturing Company, Limited, have appointed Mr. F. Barnes Spencer, M.I E.E. (late sales manager to Messrs. Ferranti Limited) as their contract manager. Mr. Spencer, who is shortly visiting the United States, will take up the appointment about the beginning of June next.

Digitized by Google

## A NEW DYNAMO.*

At a recent meeting of the Elektrotechnischer Verein Prof. E Rosenberg described in detail a novel and ingenious dynamo designed by him for the lighting of railway carriages. Numerous machines of this type have already been made, and tried in actual work, and many more of various sizes are on order for the Prussian State railways, the Bavarian State railways, the Bagdad Railway, etc., and there is no doubt as to the suitability of the machine for the work.

As is well known, the chief requirement for a successful railway lighting dynamo for use either with or without accumulators, and suitable for driving from the car axle, is the production of a practically constant uni-directional voltage (current), in spite of very wide variations of speed in either direction of rotation. Once this is attained it is possible to carry out the lighting whilst the train is running from the dynamo and accumulators in parallel, and whilst the train is at rest at a station the accumulators alone would do the work. In this way, by adjusting the dynamo current once for all, it would be possible to arrange for the cells when in parallel with the dynamo to act simply as a steadying adjunct, and to receive, on the whole, a greater charging than discharging current, and so remain as fully charged at the end of the day as at the beginning. The ordinary shunt, series, or compound dynamo is, of course, quite unsuitable for such work, and the difficulty has, up to the present, been met either by the employment of complicated differential windings or by the use of special mechanical or electromechanical devices for neutralising

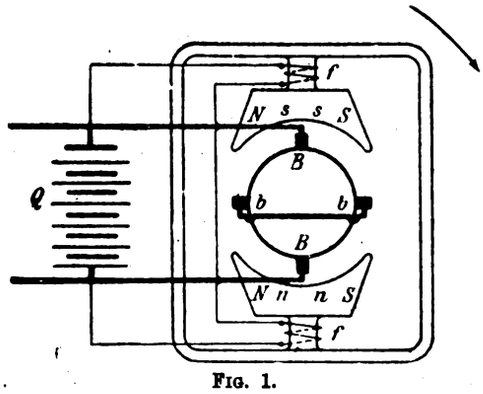


FIG. 1.

the effect of the variable axle speed—*e g*, by means of a belt or friction gear arranged to slip when the speed exceeds a fixed value. These systems can, however, only be made really automatic by the use of complicated relays and the like, and on this account cannot be considered satisfactory.

The dynamo now described is designed to avoid the use of all additional apparatus except the ordinary shunt regulating resistance, and when used with accumulators, some simple form of non-return apparatus, such as an aluminium cell, to prevent the battery sending current back through the machine when the train is at rest. Fig 1 shows the arrangement of the new machine diagrammatically. It will be seen that the chief differences from an ordinary dynamo consist in the addition of two extra sets of brushes short-circuited together and set at right angles to the main brushes, and in the proportion of pole-face area to magnet-core area. The diagram shows a two-pole machine, though the arrangement is equally applicable to multipolar ones. The armature employed differs in no way from an ordinary armature. In an ordinary dynamo the cross field set up by the armature ampere-turn at practically 90deg. to the main magnet field is found objectionable on account of its distortion of the main field, and it is suppressed, as far as possible, by saturating the pole tips, etc, but in this new machine the cross field fulfils an important function in the regulation of the output.

The machine is self-exciting, just like any shunt dynamo, but it will be simpler to consider it as connected in parallel with a battery (Fig. 1), as it would usually be when used for train-lighting. The battery sends a certain current round the exciting winding, *f f*, and produces what may be called the "original flux," shown by the small letters *s s* and *n n*, through the armature in the vertical direction. This flux produces no effect on the main (vertical) brushes because the volts induced in the different quadrants neutralise one another, but it induces a voltage between the short-circuited brushes, *b b*, and causes a current to flow through the short-circuit. This current sets up a cross flux of its own in the horizontal direction, passing from the armature into the air, through the pole-pieces back into the air and the armature, as shown by the large letters, S S and N N. This flux actually combines and forms a resultant field with the original flux, weakening the leading pole-tips and strengthening the trailing ones, but for all practical purposes the two fluxes may be considered as existing separately.

Now, the horizontal cross flux is relatively to the main (vertical) brushes in the position of the main flux in an ordinary dynamo, and consequently induces a definite voltage between these brushes. This voltage will pass a certain current through the external resistance (battery or lamps) connected to the main brushes, and this current tends to set up a vertical cross field directly opposing the original flux, *s s*, *n n*. Any reduction of this original flux, however, leads to a reduction in the short-circuit current in the horizontal cross flux, and consequently in the voltage and current of the main brushes. For every value of the ampere-turns in the coils, *f f*, there is a definite external current, and this current is always somewhat less than the current which makes the vertical (main brush) cross field ampere-turns equal to the ampere-turns in the coils, *f f*, for when this equality exists there can be no "original flux,"

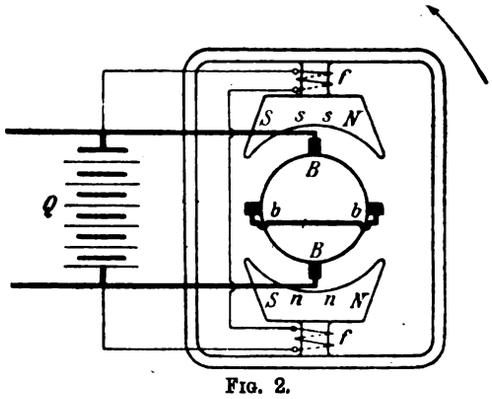

FIG. 2.

no current through the short-circuited brushes, no main (horizontal) flux, and no voltage induced between the main brushes. The external current will, in fact, always attain such a value A that the vertical flux, *s s*, *n n*, set up by the difference in ampere-turns between the exciting coils, *f f*, and the vertical cross ampere-turns due to current A will generate a short-circuit current through the horizontal brushes capable of setting up that particular value of main horizontal flux which, at the speed at which the dynamo happens to be running, and with the external resistance which happens to be across the main brushes, will produce an external current A.

The effect of reversing the direction of rotation of the machine is shown in Fig. 2. The "original flux" remains unchanged; the current in the short-circuited brushes, therefore, becomes reversed; the main (horizontal) flux consequently also reverses, and this, in combination with the reversed rotation, keeps the main external current unchanged in direction. A little consideration will show that, since the horizontal brushes are short-circuited, only a very small vertical flux would be required to produce even full-load current through the short-circuit. In the machines actually constructed it is found that at normal speed a short-circuit current equal to about 40 per cent. of the useful output current is sufficient to set up the required main flux, and in order to produce this 40 per cent. short-circuit current the ampere-turns in the coils, *f f*, have only to exceed the vertical armature ampere-turns due to the useful external current by about 10 per cent. If, therefore, the speed increases to double the normal or even to an infinite value, the utmost that can happen is the increase of the external current by something less than

* *Elektrotechnische Zeitschrift*, April 20, 1905.

Digitized by Google

10 per cent., for with a 10 per cent. increase the original flux would be entirely neutralised, and the whole action of the machine would come to an end. If, on the other hand, the speed fall to, say, 70 per cent. of its normal value, the external current tends to fall, but should it fall even as little as 10 per cent., the original flux would be immediately doubled, and this, in spite of the lower speed, would produce about 40 per cent. more current through the short-circuited brushes, and would increase the main (horizontal) flux sufficiently to compensate almost exactly for the drop in speed and leave the external current almost unchanged. The fact that the compensation for speed depends on the differential action of two almost equal quantities in this way, is the chief reason for the very exact automatic regulation obtainable with these machines.

The connection between external current and speed for one of these machines working in parallel with a battery—

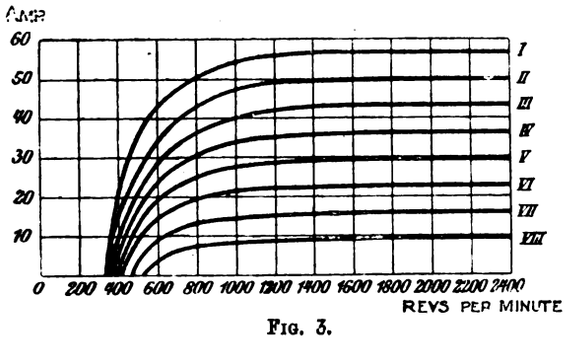

FIG. 3.

*i e*, with constant external voltage—is shown by Fig. 3. The various curves indicate the results obtained with various values of the exciting current in the coils, *f f*. Curve I. represents maximum excitation, and shows that at a low speed of about 340 revolutions (9¼ miles per hour) the terminal volts of the machine become equal to the battery volts, and that the current delivered by the machine rises rapidly with increase in speed from this point. By the time that 700 revolutions (19 miles per hour) is reached the bend in the curve is practically passed, and from there onwards the curve runs asymptotically towards a definite limiting current. Thus a change of speed from 2,400 to 800 revolutions per minute (65 to 21½ miles per hour train speed) only produces a drop in current of about 12 per cent. If the excitation of coils, *f f*, is reduced by varying the field regulating resistances, such curves as those marked II. to VIII. are obtained. At half excitation (Curve V.) the speed at which the battery voltage is reached is only slightly higher than before (390

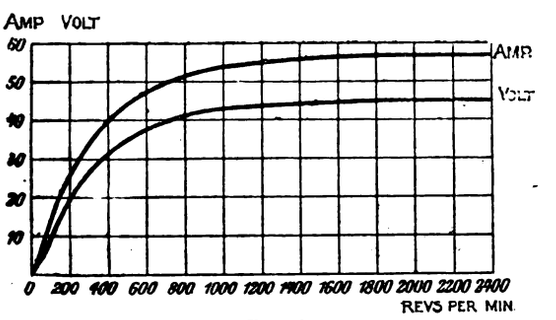

FIG. 4.

instead of 340), and the limiting value of the external current is almost exactly half that with full excitation. If the machine works direct on to a constant external resistance instead of on to a battery, the curves of volts and amperes for a given exciting current are as shown in Fig. 4. Here the curves naturally start from zero, but after a speed of 600 or 700 revolutions is reached the current curve takes almost exactly the same form as the corresponding curve in Fig. 3. When working on incandescent lamps, the effect of speed variations is even less noticeable, owing to the fall in the resistance of the lamps as they get hot. Fig. 5 shows the way in which the current through the short-circuited brushes varies with the speed. It will be seen that at low speeds (when, of course, the useful output current, which neutralises more or less of the original flux, falls off) the short-circuit current rises rapidly. In order to prevent the possibility of the short-circuit current under any circumstances reaching a dangerous value, it is found advisable to let the iron of the magnet yoke or core become saturated when the flux reaches a value corresponding to the maximum safe short-circuit current. Then, if the speed falls still lower than that corresponding to this point, the short-circuit current will decrease again, and the voltage of the machine will fall below that of the battery. In order to prevent a reversed current being sent from the battery through the machine in these circumstances, an aluminium cell is inserted between the two.

Another interesting curve in connection with this machine is given in Fig. 6. This shows the ordinary load characteristic (with constant separate excitation of the coils, *ff*) taken at constant speed, and with variable external resistance. The normal load would occur at about the

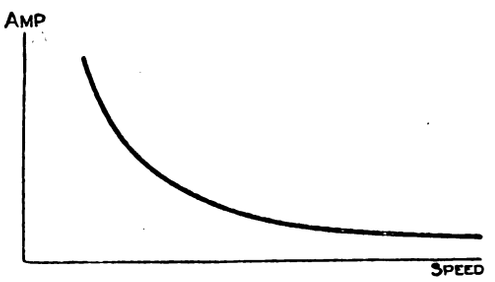

FIG. 5.

point *m*. If the machine were short-circuited the current would only rise slightly, whilst if the external resistance is increased the voltage rises rapidly in attempting to maintain a constant current. The current, however, does gradually fall off in spite of the fact that by the time open circuit is reached the terminal voltage will have risen to several times the normal value. At the same time the current through the short-circuited brushes rises correspondingly. Such a machine, therefore, needs no protection against damage through short-circuiting, but must be safeguarded against the opening of the external circuit. This can be arranged for by inserting a fuse between the short-circuited brushes.

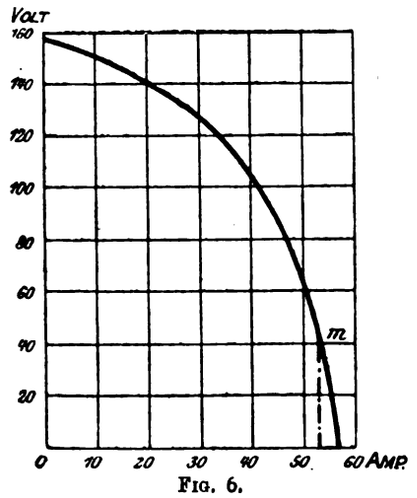

FIG. 6.

Turning next to the question of the size of such a machine as compared with that of an ordinary dynamo for the same output, a little consideration will show that the armature, in spite of the fact that it carries the additional short-circuit current, will not be appreciably affected. For instance, in the above described machine the short-circuit current at normal speed is some 40 per cent. of the useful output current, and this short-circuit current is added to the normal current in two of the quadrants of the armature, but is subtracted from it in the other two quadrants. Calling the useful current 1, the $C^2 R$ losses in an ordinary armature may be represented by 1, whilst with the same armature used in the new way the $C^2 R$ losses would be represented by

Digitized by Google

$$\frac{(1\cdot4)^2}{2}+\frac{(\cdot6)^2}{2}=1\cdot16$$

*i.e.*, they would be increased by the same amount as if the current taken from the ordinary armature were increased only some 7½ per cent.—so that if the machine is going to run most of the time at normal or higher speeds no allowance need be made, whilst if it is to run for long periods at low speeds (when the short-circuit current will be correspondingly increased) the copper sections on the armature must be somewhat increased. The commutator must be designed to carry double the usual number of brushes, and, in order to avoid crowding the brushes together too much, the brush rocker is conveniently placed over the centre of the commutator, the main brushes being placed on one side of it and the short-circuited brushes on the other side.

Coming next to the magnets, a decided saving in material is found to result from the new design. The main flux of the machine is set up in the armature, and passes from the armature into the air and the pole-shoes and back again into the armature, so that only the iron of the pole-shoes has to have sufficient section for this flux. The magnet yoke and magnet cores have only to carry the small "original flux" set up by the coils, *f f*, and can, therefore, have an extremely small section. The coils, *f f*, have only to have slightly more ampere-turns than the normal armature ampere-turns, and have only to enclose the small "original flux" iron section, so that only a very small weight of copper is necessary.

There is still the important question of commutation to be investigated. The short-circuited brushes (*b b*, Figs. 1 and 2) are working in a neutral zone, and are no worse off than those of every reversing motor—in fact, they are better off, because, as has been stated, the current to be commutated at these brushes at normal speed is only some 40 per cent. of the normal full load current. Further, the current in these brushes varies almost exactly inversely as the speed, so that the product of commutated current by speed (which determines the reactance voltage) is almost constant, and makes commutation at high and low speeds equally satisfactory. The main brushes (B B, Figs. 1 and 2) are directly opposite the middle of the "original flux" poles, but in the neutral zone of the main flux. Now the "original flux" is always only of such amount as to produce a certain limited current through the resistance of the armature and the short-circuited brushes *b b*, and the separate short-circuiting of certain sections by the brushes B B cannot cause anything more than this limited current to flow. Looked at in another way, the coils, *f f*, may be considered as helping commutation by acting the part of compensating coils, neutralising and rather overpowering the armature ampere-turns due to the main external current, just as in the Deri compensated dynamos. The compensation, however, is not very exact, for, as the external current (the current to be commutated at B B) increases, the amount by which the ampere-turns in *f f* exceed the armature ampere-turns falls off instead of increasing. On this account, as well as to allow for slight want of magnetic symmetry in the main flux, it is found preferable to cut recesses in the pole-faces just opposite the brushes B B, and so let commutation at these brushes take place in a real neutral zone. In this way the brushes B B also work under the same conditions as the brushes of an ordinary reversing motor, and, in practice, they are found to be perfectly sparkless when running in either direction.

As regards efficiency, the new machines compare favourably with ordinary machines of the same output, for the slightly increased commutator losses are neutralised by the reduced magnet winding loss. The efficiency at a given output also remains practically constant over a wide range of speed, for the increased friction losses at the high speeds are counteracted by the reduced short-circuit current loss.

In conclusion, detailed drawings and photographs were exhibited of various machines already completed, including 50-volt, 70-ampere, 240 to 1,200 revolution, four-pole dynamos (see Figs. 7 and 8) and six-pole dynamos for mounting direct on the wheel axle, and suitable for an output of 77 volts 200 amperes at from 165 to 530 revolutions.

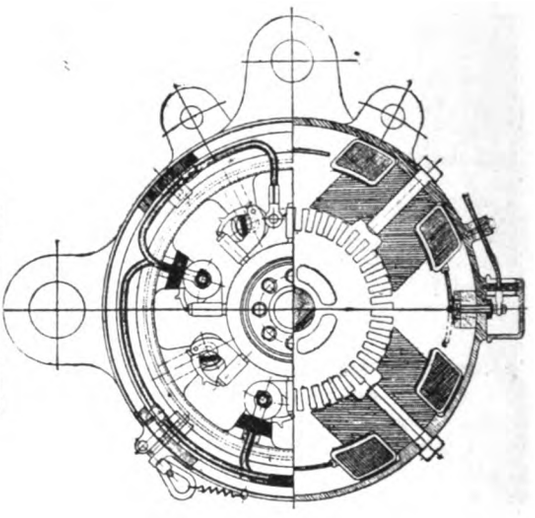

FIG. 8.

## LEGAL INTELLIGENCE.

### FIRES FROM ELECTRIC MAINS.

### Midwood v. Manchester Corporation.

This case, in which Mr. Justice Lawrance and a jury awarded the plaintiffs £677 and costs, and which was reported in our issues of March 24 and 31, was mentioned in the Court of Appeal last week.

Mr. GORDON, on behalf of the Corporation, applied for a stay of execution and also for leave to expedite the hearing of the appeal which the defendants had entered.

The MASTER OF THE ROLLS said that the application must be made to the judge who tried the case.

## COMPANIES' MEETINGS AND REPORTS.

### INDO-EUROPEAN TELEGRAPH.

The ordinary general meeting of this Company was held on Tuesday, Mr. J. Herbert Tritton presiding. Particulars of the report appeared in our issue of the 14th inst.

The CHAIRMAN said that the prospects of receipts for the next financial year were not as satisfactory as the directors could wish, mainly owing to the reductions which were possible in the rates, but he did not think it necessary to take a pessimistic view. The shareholders had been informed at the last general meeting that the Russian section of the line would pass to the Russian Government at the end of 1904. That section had become the property of the Russian Government since Jan. 31 last, and would be formally handed over to the representatives of that Government as soon as the necessary formalities were completed. As some misapprehension seemed to have arisen in that connection, he thought it would be well to mention that under the concession, which would continue until Jan. 31, 1925, the Company had the sole use of the same lines as hitherto, although they were now leased to the Company instead of being its actual property. The transfer of the Russian section from the financial point of view would, of course, be dealt with in the accounts for 1905, and would involve the writing off of the cost of that section, which stood in the balance-sheet at £313,285, against the reserve fund of £446,045. The

Digitized by Google

Company was thus entering upon a prolonged concessionary period with its capital absolutely intact, and a list of investments which could stand the most rigorous inspection.

The report was adopted.

## NORTH OF SCOTLAND ELECTRIC LIGHT AND POWER.

The annual general meeting of this Company was held at Montrose last week, Dr. Stone presiding.

The report stated that the lamp connections in Montrose had been increased from 11,670 to 15,130, and in Brechin from 7,359 to 12,081, and up to the present time 1,920 additional lamps had been applied for in Montrose and 2,050 in Brechin, making a total for the two towns of 31,181 equivalent 8-c.p. lamps. The result of the year's trading, including a balance of £469. 15s. 2d. brought forward from the previous year, showed a profit of £2,422. 4s. 9d., which, after paying interest on loans amounting to £1,659. 3s., as against £918 paid in 1903, left a balance of £727. 1s. 9d. available for distribution. The directors recommended a payment of a dividend at the rate of 2½ per cent., which would absorb £293. 12s. 3d., leaving a balance of £433. 9s. 6d. to be carried forward.

The report was adopted.

## KALGOORLIE ELECTRIC TRAMWAYS.

The first annual meeting of this Company was held at Winchester House last week, Mr. A. H. P. Stoneham presiding. Particulars of the report appeared in our issue of the 14th inst.

The CHAIRMAN remarked that, satisfactory as their profits were, they could make much more in the future. They were now paying the Kalgoorlie Electric Power Company 4d. per unit for power, which was a reasonable rate when they entered into the contract, because at that time water was very expensive, and the power company, not believing that the Government water scheme would be successfully carried through, went to enormous expense in erecting condensers. Fortunately for Kalgoorlie the Government water scheme has been successful, and the vast expenditure on condensers had proved to be totally unnecessary, so they were now putting up their own plant, and would get power a great deal cheaper than the power company could afford to supply them. He did not anticipate that the shareholders would be asked for capital.

The accounts were unanimously passed.

## CAPE ELECTRIC TRAMWAYS.

An extraordinary general meeting of this Company was held on the 19th inst. for the purpose of considering the following resolution: "That Mr. Alfred Parrish be and he is hereby removed from the office of director of the Company."

Colonel Sir CHARLES EUAN-SMITH (the chairman of the Company) reviewed the transaction in connection with the Camp's Bay line, which had not turned out so favourably as had been expected. Mr. Parrish, who had not taken a very active part in the Company's business of late, had recently issued, on his own initiative, a circular in which he sought to exonerate himself and to impugn the action of his colleagues, who, under the circumstances, could not co-operate with him any longer.

After some discussion the resolution was put to the meeting and lost on a show of hands. A poll was demanded, which was taken at once.

The poll resulted as follows: in favour of the directors' motion, 291,327 votes; against the motion, 54,711 votes. The motion was then declared to be carried by the requisite majority.

## MARKET DRAYTON ELECTRIC LIGHT AND POWER.

The annual meeting of this Company was held last week, under the presidency of Mr. R. C. Donaldson-Hudson.

Although only a little over two years since the Company commenced, it was shown that during the year the number of lamps connected with the works had increased from 4,759 to 7,161. There was a net profit of £562, which, with the balance of £75 brought forward, gave a total of £630. This it was decided to deal with by writing off £32 from the preliminary expenses, to carry £368 to the reserve fund and renewal account, and the balance of £230 to the next account.

## OSWESTRY ELECTRIC LIGHTING.

The annual meeting of this Company was held on Tuesday, Mr. Wynne Corrie, the chairman, presiding. It was reported that the increase in the receipts continued to be very satisfactory, and that the available balance of profit amounted to £538. After adding £163 to the reserve fund, it was decided to declare a dividend of 4½ per cent.

## ORIENTAL TELEPHONE AND ELECTRIC.

The report for the year ended Dec. 31, 1904, to be presented at the meeting to-day, states that including £1,737 brought forward at Dec. 31, 1903, and after deducting the interim dividends of 3 per cent. paid Nov. 1 on both the preference and ordinary shares and other charges, the amount to be dealt with is £12,422. The directors recommend a final dividend of 3½ per cent. on the ordinary shares, making 6½ per cent. for the year, transferring to reserve account £3,000 leaving to be carried forward £1,721. The Telephone Company of Egypt has been enabled to declare dividends of 7½ per cent. for the past year on both its preferred and deferred shares, which have been included in the accounts of this Company. The Egyptian company has received a further contract from the Government of the Khedive for the installation of an additional batch of provincial telephone lines. At Singapore land has been purchased for new exchange premises, which are now in course of erection. At Maulmain a suitable building has also been purchased for exchange and residential premises. The Indian local companies have paid the same dividends as for 1903. The Bombay Telephone Company's new premises will be completed very shortly. The work of underground cabling its system in the city of Bombay has already commenced. The Government of India having compulsorily acquired the premises in the occupation of the Bengal Telephone Company in Calcutta, the removal of that company's central exchange has become necessary. The Government has granted compensation for this compulsory removal. New and improved switchboards have been ordered, and it is hoped these will be installed during the autumn, by which time it is expected underground cabling operations will also be in progress. In Rangoon, Maulmain, and Madras the work will be commenced within the next 12 months. The China and Japan Telephone and Electric Company has received a license from the Hong-Kong Government for a term of 25 years. The system there will now be thoroughly overhauled and reconstructed with underground and overhead cables. The business at Hong-Kong is progressing very favourably.

## BRITISH COLUMBIA ELECTRIC RAILWAY.

An extraordinary general meeting of this Company was held at Winchester House on the 19th inst., Mr. R. M. Horne-Payne presiding, to approve an agreement providing for the electrification and operation by this Company of the railway line from the city of Vancouver to Steveston, Lulu Island, to increase the capital to £1,000,000 by the creation of 150,000 new shares of £1 each, and to adopt new regulations.

Confirmatory resolutions were unanimously adopted.

## CALCUTTA ELECTRIC SUPPLY.

The report for the year 1904 states that the number of units of electrical energy sold during the year was 2,760,457, compared with 2,044,681 for the preceding year, an increase of 35 per cent. The gross revenue from all sources amounted to £60,243, compared with £47,139, an increase of 27¾ per cent. The working costs, including provision for renewals, were £30,744, compared with £25,552, an increase of 20 per cent., and the net revenue £29,499, compared with £21,587, an increase of 36½ per cent. The directors, in view of the capital outlay, have increased the amount set aside for renewals fund account to £11,000, which is £2,500 over the amount set aside in the preceding year. Of the sum so provided, £4,092 has been expended in repairs and renewals, and £370 has been written off, leaving a balance of £21,815 carried forward as a reserve for renewals. During the year the directors made a further issue of 20,000 shares of £5 each at a premium of £1 per share. The premiums, less the cost of issue, have been added to the reserve fund, which now stands at £54,592. The available balance of net profit, after deducting the interim dividend paid in November, interest on loans, and income tax, is £21,279, and the directors recommend a final dividend at the rate of 10 per cent. per annum for the half-year, making 8 per cent. for the year, and the balance of £4,720 is carried forward.

## RAND CENTRAL ELECTRIC WORKS.

The report for 1904 shows a gross profit of £48,450, and after providing £16,670 for depreciation, there remains a balance of £31,780. From this has to be deducted the balance standing to the debit of profit and loss account, as at the end of 1903, of £11,947, and £307 balance of royalty due to the Transvaal Government under the concession, leaving a net balance of £19,525. Out of this the directors recommend a dividend of 5 per cent. per annum, carrying forward £4,525 to the new account. The power supplied during the year has yielded a revenue which exceeds that of the preceding year by £24,305, and, as a result, the working profit, before deducting the sum allocated to depreciation, amounts to £48,450, as compared with £28,540 for 1903. The receipts derived from the supply of power and rent of plant aggregated £94,818, against £70,513 for the year 1903. Interest on deposits and profit on exchange, etc., have further increased the revenue by £1,361, bringing up the gross receipts for the year to the sum of £96,179.

## WOKING ELECTRIC SUPPLY.

The report for the year ending Dec. 31, 1904, states that the total revenue was £10,356. 16s. 7d., and the expenditure connected with the generation and distribution of electricity and management amounted to £6,031. 18s., leaving a balance of £4,324. 18s. 7d., to which has been added £785. 0s. 7d., the amount brought forward from last year, making a total of £5,109. 19s. 2d. The directors propose to appropriate this as follows; payment of interest on the 4½ per cent. debentures £1,074. 15s. 1d., payment of interest on temporary loans £215. 6s. 6d., payment of dividend on the 6 per cent. cumulative preference shares to Dec. 31, 1904 (six months to June 30, 1904, having been paid on Oct. 1, 1904), £1,332. 7s. 2d., payment of a dividend of 5 per cent. per annum on the ordinary shares £771. 18s. 7d., to depreciation fund account £1,000, leaving a balance to be carried forward to the credit of profit and loss account of £715. 11s. 10d. The following table will show the rate at which the Company's business has progressed during the last four years: 1901, number of consumers 417, lamps connected 15,090, revenue £4,466. 15s.; 1902—543, 19,566, £6,276. 2s. 5d.; 1903—660, 25,010, £7,951. 15s. 10d.; 1904—783, 29,566, £10,340. 19s. During the year 123 new consumers were obtained.

## EASTERN EXTENSION TELEGRAPH.

The report for the half-year ended Dec. 31, 1904, to be submitted to the meeting on the 3rd proximo, states that the gross receipts have amounted to £331,788, against £265,259 for the corresponding half-year of 1903. Working expenses, including £35,471 for maintenance of cables, absorb £150,035, against £142,419 for the corresponding period of 1903, leaving a balance of £181,753. From this is deducted £2,793 for income tax, and £12,048 for interest on mortgage debenture stock, leaving a net profit for the half-year of £166,911. After adding £110,270 brought forward from the previous half-year there is an available balance of £277,181. One quarterly interim dividend of 1½ per cent. has been paid for the half-year, and it is now proposed to distribute another of like amount. It is also proposed to pay a bonus of 4s. per share, or 2 per cent., making a total distribution of 7 per cent. for the year 1904. The sum of £120,000 has been transferred to the general reserve fund, leaving £22,181 to be carried forward. Since the close of the financial year the capital account has been increased by a further issue of £150,000 of 4 per cent. mortgage debenture stock, thus making the total issue to date £752,400.

## BATH ELECTRIC TRAMWAYS.

The directors state that during the year 1904 the construction of the system originally contemplated under the Company's light railway order was continued, and sections of the line were opened from time to time, until, on Aug. 1 last, the final section was opened for traffic. A further order, acquired in the latter part of 1903, in connection with the extension over the Midland Railway, and known as the Midland bridge route, is still in course of construction. In November, 1904, powers were sought from the Board of Trade for the construction of two additional lines, one of which—the extension to Newton St. Loe about 1 mile 5 furlongs 9 chains in length—was authorised by the Light Railway Commissioners. The capital account of the Company shows an expenditure to Dec. 31, 1904, of £302,545, which includes, under the advice of counsel, the cost of registration and formation, all management of the Company prior to opening for traffic, and the expenses of loans, etc., raised for capital purposes. The traffic receipts for the year 1904 amounted to £33,161, which must be regarded as satisfactory, especially as in the earlier part of the year the Company was operating, under difficult conditions, only a portion of its system. After charging operating and administration expenses, there remains a balance of £11,250, from which must be deducted interest accrued on the 4½ per cent. debenture stock £737, and dividend on the preference shares to Dec. 31, 1903, paid Dec. 29, 1904, leaving a balance of £7,670. Out of this the directors recommend the payment of a dividend at the rate of 5 per cent. per annum upon the preference shares to Dec. 31, 1904, which will absorb a sum of £3,750, leaving to be carried forward £3,920.

## RIVER PLATE ELECTRICITY.

The report for 1904 states that the net revenue for the year, after providing debenture interest, writing off depreciations and the balance of preliminary expenses, amounts to £10,436. To this must be added £2,829 carried over from last year, making an available balance of £13,265. The directors recommend the payment of the year's dividend upon the 6 per cent. preference shares, that £4,000 be placed to a contingency fund, and that the balance of £3,265 be carried forward. The accounts might have permitted a distribution on the ordinary shares, but the Board are of the opinion that, pending the reconstruction of the Company's stations now in progress, it is in the best interests of the shareholders that they should carefully husband their resources. During the year the transfer of the Buenos Ayres property to the German Trans-Oceanic Electric Company of Berlin has been formally completed. The agreement between the Company and the Government of the province of Buenos Ayres for the acquisition by the Company of the Government's interest in the La Plata station and for the extension of the public lighting contract, having been approved by the Chamber of Deputies and the Senate, has been executed by the governor of the province. The Board have sanctioned the erection of a new and enlarged station upon the site acquired. It is hoped that the new station will be in operation and the transfer over from the existing station substantially complete within 15 months. Important improvements and extensions have also been authorised at Tucuman, the works in connection with which have already made some progress.

## COVENTRY ELECTRIC TRAMWAYS.

The report for 1904, to be presented at the meeting to-day, states that the net earnings for the year have amounted to £3,410, a decrease of £1,232, as shown by the following figures: gross earnings, £15,981, a decrease of £892; cost of operation, £12,571, an increase of £340. After allowing £1,190 for interest paid on the £34,000 mortgage bonds, a balance remains of £2,220, which, added to the sum of £1,373 brought forward from last year, makes a total of £3,593 available for distribution. The directors recommend a dividend of 2 per cent. for the year on the amounts paid up on the share capital, and that £500 be placed to reserve. This will absorb £2,846, leaving a balance of £647 to be carried forward. The decrease in earnings above referred to is entirely owing to the unavoidable loss of traffic and disorganisation of the tramway service caused by the reconstruction of the portion of the system referred to in last year's report. Those works were commenced in October, 1904, and the reconstruction of the tracks within the city boundary was completed in February last, whilst the extensions to Earlsdon and Chapel Fields authorised by the Act of 1903 were completed and came into operation on March 22, 1905. There only remains the reconstruction of a portion of the line from Foleshill to Bedworth, and it is expected that through traffic on that route will be resumed about the end of May.

## KALGOORLIE ELECTRIC POWER AND LIGHTING.

The report for 1904, to be submitted at the meeting on the 3rd proximo, states that contracts for power have been made during the period under review with several of the largest gold-mining companies, the full benefit from which will not be derived, however, for a few months, pending completion of the erection of the machinery ordered by them. Considering the amount of power to be taken under these contracts, and the extensions to the northern end of the field which are in progress, it is evident that the load factor of the plant will be much improved. The profit on working for the year—namely, £18,334—is nearly 100 per cent. above that of the previous year. After paying debenture interest and London expenses, the directors propose to carry to reserve for depreciation £6,750, writing off the balance of preliminary expenses £5,487, and the cost of issuing debentures £344, making provision for the premium payable on redemption of debentures £660, and carrying forward £812. The whole of the bank overdraft and bills of acceptance, amounting in the last balance-sheet to £13,651, has been paid off, and at Dec. 31 last there was a cash balance of £4,713. Although the plant is efficiently maintained out of revenue, the directors have deemed it advisable to establish a reserve against depreciation, which, with the contingency fund of £1,000, gives a total on reserve accounts of £7,750.

## AUCKLAND ELECTRIC TRAMWAYS.

The report for 1904, to be presented at the meeting on the 1st prox., states that during the year £85,100 debenture stock has been disposed of, and the issued share and debenture capital now amounts to £585,100. The total capital expenditure during the year amounted to £63,951. Traffic receipts for the year amounted to £110,573, as compared with £81,772 for the previous year, and the total revenue to £112,429. After deducting all expenses chargeable to revenue, including £12,235 for debenture and other interest, £2,521 for rental and percentage of profits payable to the Auckland City Council, and £4,658 balance of expenditure in connection with the Kingaland accident, there remains a profit of £26,275, which, added to £2,323 brought forward from the previous account, makes £28,598 available for distribution. The directors recommend that there should be reserved to meet depreciation £7,500, and after paying a dividend at the rate of 6 per cent. per annum, there remains to be carried forward £3,098. The depreciation and reserve fund will then stand at £18,050. Since the date of the last report the system has been extended by the completion of a further 1·44 route miles, which were opened for traffic on Aug. 24, making the total length of the Company's lines at present under operation 18·64 miles. It is intended to immediately construct a further extension of 0·57 mile, which will complete the system as at present determined upon. The Company has been approached by various local authorities in the vicinity of Auckland with a view to the extension of the Company's system into their districts, and these proposals are receiving the careful consideration of the Board. The serious accident which occurred on Dec. 24, 1903, involved the Company in an expenditure of £8,658 in excess of the amount covered by insurance. To meet this £4,000 has been provided by the utilisation of the amount set aside out of the revenue in 1903 for contingency provision account, the balance being debited to profit and loss account for 1904. To meet improving traffics the rolling stock has been increased to 55 by the purchase of 12 additional passenger cars; only four of these were available up to the end of the year. An additional 600-kw. set has been installed in the Company's generating station, which is now capable of an output of 1,525 kw. The resolution of the Auckland City Council extending the Company's tenure of the lines in their district until June 1, 1932, has been confirmed by the ratepayers and embodied in a further deed of delegation dated May 18, 1904.

## NEW COMPANIES REGISTERED.

**Richardson Electrical Company, Limited.**—Capital, £2,500. Objects: to carry on the business of electrical, gas, and mechanical engineers, electricians, suppliers of electricity, etc. Registered office: 16, Dorset-street, Baker-street, W.

**Edinburgh Suburban Electric Tramways Syndicate, Limited** Capital, £10,000. Objects: to construct, lease, or otherwise acquire, equip, maintain, and work by electricity, steam, horse, or other power tramways between any part of Edinburgh or Leith and any places within the counties of Midlothian, East Lothian, and West Lothian, etc. Registered office: 45, Victoria-road, Seacombe, Cheshire.

**Dundee, Broughty Ferry, and District Tramways Company, Limited.**—Capital, £90,000. Objects: to purchase or otherwise acquire the control of the statutory rights and powers under the Dundee, Broughty Ferry, and District Tramways Order (Confirmation Act) for the construction and working of certain tramways in the county of Forfar, and to construct and maintain any tramways or railways in the United Kingdom or elsewhere.

**Wandsworth Electrical Manufacturing Company, Limited.**—Capital, £4,000. Objects: to acquire the business of electrical manufacturers carried on by E. T. Davies, A. Reynolds, F. J. Ritchie, A. B. Smith, M. H. Galsworthy, and S. S. Galsworthy, trading at 9, St. Paul's-square, Birmingham, as the Wandsworth Electrical Manufacturing Company, and to carry on the business of art metal workers, manufacturers of and dealers in all kinds of electrical fittings and

Digitized by Google

accessories, electricians, engineers, suppliers of electricity for light, heat, motive power, and other purposes, etc. Registered office: 9, St. Paul's-square, Birmingham.

### Liens Registered.

**Auto-Electric Rifle and Target Company, Limited, London, W.** Lien registered April 11 for £100 7 per cent. debentures, part of £5,000; amount previously issued, £2,700; no trustees; charged on the undertaking and all the property, present and future.

**Yorkshire Electric Tramways Construction Syndicate, Limited.**—A debenture, dated March 24, 1905, to secure £50,000 has been registered. Property charged: the company's undertaking and property, present and future, including uncalled capital (if any), subject to a debenture dated July 22, 1904, for securing £70,000. Holder: H. S. Leon, Bletchley Park, Bucks.

**Kidderminster and District Electric Lighting and Traction Company, Limited.**—A trust deed, dated April 5, 1905, to secure £30,000 debenture stock (with power to issue further debenture stock, ranking *pari passu*, up to a total amount not exceeding the issued capital for the time being) has been registered. Property charged: the company's undertaking and property, present and future. Trustees: E. Garcke, Litton House, near Maidenhead; and C. S. B. Hilton, 41, Roland-gardens, Kensington.

## CONTRACTS FOR ELECTRICAL SUPPLIES.

**Portsmouth.**—The Council require annual stores for tramways. Tenders by May 1.

**Edinburgh.**—The Corporation invite tenders for water-tube boilers. Tenders by May 8.

**Dublin.**—The Port and Docks Board invite tenders for an electric generating station. Tenders by May 15.

**Bournemouth.**—The Town Council invite tenders for Contract No. 6—11 electric cars. Tenders by 29th inst.

**Cataquoxes (Spain).** — The local light and power company require tenders for electrical plant. Tenders by July 1.

**Montreal.**—The Montreal Water and Power Company, 107, St. James-street, require tenders for machinery for a pumping station.

**Johannesburg.**—The time for sending in tenders for this contract (particulars of which appeared in former issues) is May 8 (London).

**Hull.**—The Trustees of the William-street Primitive Methodist Chapel invite tenders for lighting premises by electricity. Tenders by April 29.

**Baeza (Spain).**—The Municipality require tenders for supply and maintenance for 10 years (from Aug. 4) of public electric lighting. Tenders by May 3.

**Paris.**—The Colonial Office, 4 bis, Rue Jean-Nicot, require tenders for the supply of lamps and lighting accessories for three years. Tenders by May 23.

**Glasgow.**—The Corporation invite tenders for the electric light wiring and fittings complete required in connection with the reception house in Braid-street. Tenders by May 1.

**Cork.**—The Cork Electric Tramways and Lighting Company, Limited, invite tenders for the supply of white wood casing and capping. See advertisement.

**Liria.**—The Municipality require tenders for installation of electric lighting; 2,000 c.p. are required for street-lighting, for which it is proposed to pay 6,000 pesetas per annum.

**Dax (Province of Landes, France).**—The Municipality require tenders for their concession to erect and work electric lighting for 35 years. Tenders to the Mayor by May 14.

**French West Africa.**—The Governor-General of French West Africa, at Dakar, requires tenders for the erection and equipment of a central station at that place. Tenders by May 15.

**Laventhem (Belgium).**—The Municipality require tenders for erection of central station, laying of mains, etc. Particulars (3s. 4d.) may be obtained from the Secretary of the Mayor of that place.

**Bournemouth.**—Tenders are invited for the following, for the Corporation Tramways (Christchurch extension): Contract No. 5—feeder cables, troughing, excavation, etc. Tenders by April 29.

**Wimbledon.**—The Urban District Council invite tenders for the supply and erection of a 1,000-kw. steam-driven turbo-alternator, with condensing plant, high-tension switchgear, and pipework. Tenders by April 28.

**Antwerp.**—Tenders will shortly be invited by the Belgian State Railways for the installation of electric light in their local railway station. Specification No. 619 may be obtained from the Government Railways Office, Brussels.

**Bristol.**—The Docks Committee invite tenders for the construction, delivery, erecting in place, fitting, testing, and maintenance for 12 months after completion of two electric goods lifts and one electric passenger lift. Tenders by May 1.

**London.**—The London County Council invite tenders for the supply, erection at its generating station, East Greenwich, S.E., and maintenance for a period of 10 years, of a battery of 280 accumulator cells having capacities of 645 ampere-hours at a three-hour discharge rate and of 450 ampere-hours at a one-hour discharge rate. Tenders by May 16. Full particulars in advertisement columns.

**Switzerland.**—M. R. Vontobel, of Winterthour, and M. Charles Probst, of Lucerne, have obtained a concession for the construction of a narrow-gauge electric railway from Meiringen to Gletsch. The total cost of the enterprise is estimated at £241,600; £19,600 is to be expended on rolling-stock.

**Irvine (Scotland).**—The Corporation invite tenders for the supply and erection of the following plant: (Contract 1) buildings; (Contract 2) power-house plant—(Section A) suction gas plant, gas-engines, and generators; (B) balancers and boosters; (C) battery of accumulators; (D) switchboard; (E) crane; (Contract 3) mains—(Section A) cables, trenches, etc.; (B) converting street lamps; (C) meters. Tenders by May 15.

**London, N.**—Tenders are invited for the road work, platelaying, and paving, etc., required for the construction for electrical traction on the overhead trolley system of the short length, equivalent to about three-fourths of a mile of single track, of authorised tramway in Archway-road, Highgate, between the Archway Tavern and the Highgate Archway, in the metropolitan borough of Islington, for the London County Council. Tenders by May 8.

### RESULTS OF TENDERS.

**Croydon.**—The County Council have accepted the tender of W. Cory and Son for the supply of coal to the electricity works.

**Hull.**—The Telephones Committee have accepted the tender of the Electrical Company, Charing Cross-road, London, at £3,374. 4s. 4d., for the supply of cables required for extensions.

**Morecambe.**—The Town Council have accepted the tender of C. Lindley and Co. for blowers for the electricity works, and instructed the engineer to carry out the work at a cost of £50.

**Barrow-in-Furness.**—The Corporation have accepted the tender of W. Gradwell and Co., Barrow-in-Furness, at £4,271. 8s., for erection and completion of extensions to the electricity works, Buccleuch-street.

**Liverpool.**—The Mersey Docks and Harbour Board have accepted the tender of the Electrical Company for the supply and erection of arc lamps, posts, cables, etc., required for lighting the entrance to Sandon Dock, the north and south passages to Huskinson Dock, and the Huskinson Dock and branches.

**Pontypridd.**—The Directors of the Great Western Collieries have accepted the tender of the Electrical Company, Limited, for the electrification of their Penhriw colliery and the supply of the following materials: high-tension transmission lines, sub-station equipment, switchboards, power and lighting transformers, motors for electric haulages and dip pumps, motor-generator, and motor-driven high-lift centrifugal pump.

**Woolwich.**—The Council have received the following tenders for lighting the union infirmary and nurses' home, etc., by electricity:

| | | | |
|---|---|---|---|
| Barlow and Young | £1,983 | 0 | 0 |
| A. H. Marshall | 1,500 | 0 | 0 |
| Bosz | 1,250 | 0 | 0 |
| J. C. Berry | 1,194 | 0 | 0 |
| Bean Company | 1,154 | 14 | 0 |
| Lightfoot | 1,027 | 15 | 0 |
| National Electrical Construction Company | 998 | 0 | 0 |
| Woolwich Borough Council | 892 | 16 | 0 |
| Lea, Son, and Co. | 845 | 0 | 0 |
| A. H. Wood | 817 | 0 | 0 |
| Clements, Booker, and Co. | 747 | 15 | 0 |

## BUSINESS NOTES.

### TRACTION.

**Salford.**—The route from Heaton Park to Bury, linking up the two towns, was opened last week.

**Leith.**—A recent *plébiscite* shows the inhabitants to favour Sunday running by a majority of two to one.

**Tyneside Tramways.**—The extension from Front street, Whitley Bay to the Links has been opened for traffic.

**Exeter.**—Major Pringle last week inspected and approved on behalf of the Board of Trade the St. Thomas and Heavitree sections.

**Dartford.**—The contractors, Messrs. J. G. White and Co., expect to commence the construction of this tramway system in a few weeks.

**Gorton.**—The Urban District Council publish formal notice of the provisional order for the construction of tramways just issued by the Board of Trade.

**Luton.**—The Corporation have published the statutory notice of the grant of a provisional order by the Board of Trade for the construction of tramways.

**Erith.**—The consulting engineers reported at last week's meeting of the Urban District Council that satisfactory progress is being made with the construction of the track.

**Aberavon.**—The Aberavon District Tramways Syndicate publish formal notice of the provisional order for the construction of tramways just issued by the Board of Trade.

**Sunderland.**—New offices and headquarters, erected at a cost of £6,000, for the Corporation tramways were opened last week. A recreation room for the employés and a reading-room are included.

**Perth.**—The tramway reconstruction is progressing. A number of poles for the overhead equipment have been erected in the Glasgow-road, and in the centre of the town the fittings are well advanced.

**Rochdale.**—There is a loss on the year's working—or, rather, non-working—of the Corporation tramways amounting to £8,358. Owing to the work of reconstruction only one or two small sections have been in operation.

**British Electrical Engineering Co.**—The directors propose to pay the full dividend of 6 per cent. on the preference shares, to place £7,000 to the general reserve, to transfer £6,500 to the depreciation reserve, and to carry forward £3,060.

Digitized by Google

**Bath.**—At the meeting of the Bath Electric Tramways, Limited, on Wednesday, Sir Vincent Caillard, who presided, said that the directors proposed to introduce a system of motor omnibuses to feed the tramways, as they would be able to penetrate much further into the country than the trams.

**Edinburgh.**—The Dolter Surface-Contact Company have exhibited at Edinburgh a model installation of their system, which was inspected by several members of the Corporation. As various electric lines in and around the city are projected, considerable interest was manifested in the system, especially from the æsthetic point of view.

**Clydesdale.**—It is reported that the engineers representing the Caledonian Railway have been engaged in surveying the Carluke, Orchard, and Crossford districts, with a view to the extension of the Caledonian line into the extensive fruit-producing district of Clydesdale. A tramway extension has also been in contemplation.

**City of Birmingham Tramways Co.**—In their annual report the directors recommend a further dividend of 2½ per cent. and a bonus of 5 per cent., making 10 per cent. for the year, and leaving a balance of £54,007 to be carried to the reserve fund (increasing it to £296,751) to provide for depreciation of assets, redemption of debentures, and for general purposes.

**Parcel Traffic.**—A proposal to develop parcel traffic by car was considered at a meeting of the Dundee Tramway Committee on Tuesday. A suggestion was made that at certain points on the routes shopkeepers and others should be arranged with to take in and receive parcels, and that the department should make provision for their delivery. The manager was instructed to formulate a scheme.

**Chester.**—The annual report for the year ending March 25 gives total receipts, £9,221. 10s. 9d.; average per day, £25. 5s. 3·4d.; receipts per car mile, 8·1d.; passengers, 2,095,518; mileage, 271,718·25; total units used, 251,760; current used per mile, ·92 of a unit. No serious injury to any passenger occurred throughout the year. The rolling-stock has been maintained in good condition.

**Blackpool.**—Colonel Druitt has visited Blackpool on behalf of the Board of Trade, and inspected the double line of electric tramways which the Corporation have constructed along the newly-widened promenade between the north and central piers. With the exception of a small section near to the Hotel Metropole, there is now a double line along the whole length of the promenade from South Shore to the Gynn (three miles).

**Tranent.**—The committee recently appointed at a public meeting in Tranent to act conjointly with the Town Council for the purpose of inducing the National Constructive Electric Tramways Company to stretch their system from Levenhall to Tranent have now finished their canvass. The petitioners for the electric tramway system from Tranent, Elphinston, Ormiston, Macmerry, etc., number over 6,000. These numbers do not include some 2,500 from Wallyford and Drumore.

**Tramways and Light Railways Estates Co.**—The report of the Tramways and Light Railways Estates Company, Limited, for 1904, to be submitted at the meeting to-day, states that the total revenue for the year, including £176 brought forward, amounts to £1,276, and expenses to £847, leaving a credit balance of £429. The directors propose to apply in reduction of goodwill account £100, and after paying a dividend at the rate of 2½ per cent. per annum, there remains to be carried forward £78.

**Easter Traffic.**—Although the clerk of the weather was none too well disposed during the holidays, some of the tramway systems succeeded in beating their records. At Salford the receipts for the week ending Monday amounted to £4,803. 2s., an increase of £98 as compared with the corresponding week last year, and £426. 8s. 3d. over the amount earned during Easter week last year. At Bradford the receipts were nearly £650 in advance of the revenue during Easter last year. For the five days from Good Friday to Easter Tuesday the receipts totalled £4,634, against £3,986.

**Municipal Trams.**—At the eighth annual meeting of Thomas Tilling, Limited, last week, Mr. R. S. Tilling, who presided, continued the attack on municipal trams which his company initiated recently in a circular. It will be remembered that this elicited a spirited reply from the Chairman of the London County Council Highways Committee. After congratulating the shareholders upon the progress of the motor 'bus, Mr. Tilling stated that municipal tramways were instituted for the relief of the rates, and yet in only 12 of the 43 boroughs possessing them was any contribution made to the rates.

**Crowding at Termini.**—The Easter holidays have again illustrated the difficulty that arises, particularly on special occasions, in dealing with tramway traffic at the termini. The queue erected at the Blackfriars termini some two years ago has been found very satisfactory, but the idea has not been generally adopted in the Metropolis. The arrangement of the passengers in queues by means of pens, so that they are kept in position, has answered excellently in the provinces, notably at Sheffield, where it has been in use for several years; and this method seems to provide the rational solution of the problem.

**North Staffordshire Railway Co.**—In order to compete successfully with the electric trams the North Staffordshire Railway Company are establishing a system of steam motor vehicles, which will run on their ordinary rails. At present the service of trains between many of the North Staffordshire towns and colliery districts is very inadequate, and the object is to link up the entire north of the county by a frequent service of these motor trains. The vehicles will stop almost anywhere to pick up and set down passengers. The cars, which are being built in Manchester, have a seating capacity for 40 passengers each, and accommodation for a large quantity of luggage.

**Belfast.**—At an extraordinary general meeting of the Belfast Street Tramways Company last week, the Chairman recapitulated the result of the arbitration, and the directors' scheme for distributing the amount awarded was unanimously agreed to. It is reported that another strike has occurred in connection with the work of reconstruction, the paviors claiming time rates on the ground that sufficient material was not forthcoming to justify piece rates. At the meeting of the Tramways Committee, Mr. Nance, the general manager, said that the present rate of progress of their cars was six miles per hour. He proposed to start the electric cars at eight miles per hour.

**Accidents.**—A fatal accident occurred on the Manchester Corporation tramways on Saturday. A labourer named James Callary was running across Oldham-road when a car knocked him down. Presumably the lifeguard failed to act, as the deceased was stated to have been dragged along for seven or eight yards. When conveyed to the Manchester Royal Infirmary he was suffering from fracture of the skull, and death occurred shortly afterwards. On arriving at the Bradley terminus of the Huddersfield Corporation system on Sunday a driver of one of the trams lost control of the car, which left the rails, and crashed against a wall, finally falling into a garden. The driver jumped from the platform and was seriously injured, and the conductor was also badly hurt, but the only passenger escaped uninjured.

**Bury.**—At the monthly meeting of the Tramway Committee, a letter was read from the Radcliffe District Council asking when the committee would be prepared to go on with the negotiations in connection with the Radcliffe tramways extension to couple up the system with Bolton and Bury by way of Bolton-road. A discussion followed, and it was decided to report to the Town Council that the committee were unanimously of opinion that the Bolton-road extension should be proceeded with, and asking for the instructions of the Council. It was also decided to ask for the instructions of the Council with regard to the extensions of Jericho and Limefield sections to the borough boundaries. It was reported that the Black-lane section would probably be ready for inspection in a fortnight, and that the Dumers-lane section would be ready by Whitsuntide.

**Glasgow.**—A slight obstacle is reported concerning the extension of the tramways from Thornliebank to Barrhead, the parties being the Glasgow Corporation (as the tramway owners) and the Upper District Committee of Renfrewshire (who are the municipal authority in the district affected). The result of previous negotiations between these bodies was recently chronicled in our columns. The extension in question necessitates the rebuilding of Spier's Bridge, Thornliebank, and the District Committee stipulates that the ground for this purpose shall be provided by the Corporation, who will not agree to the request. Meantime a petition has been signed in Thornliebank in favour of the extension, and the volunteers who shoot at the Patterton and Darnley Ranges, which adjoin the proposed new line, are also being asked to adhibit their names. The petition will be presented in a short time to the Tramway Committee. The negotiations between the District Committee and the Paisley Tramways Company have not yet been completed. The company object to doubling the line between Cross Stobbs and Barrhead, and the county authorities insist that this shall be done.

**Heywood.**—At a meeting of the Tramways Committee last week, the suggested agreement with the Bury Corporation for the running of the electric cars between Bury and Heywood was submitted and approved. The terms which have been provisionally accepted by Bury and Heywood are that Heywood shall construct and equip the tramways, which shall be worked by Bury at a charge of 4½d. per car mile, Heywood taking balance of receipts, maintaining the track, and supplying current, while Bury will be responsible for maintenance of overhead equipment. It is understood that in view of the agreement originally arrived at between Bury and Rochdale, the provisional agreement has been submitted to the Rochdale Committee, who, it is expected, will agree to run cars to the Heywood Market-place on similar terms. If, however, Rochdale does not agree to these terms, there is a probability of Bury running cars as far as the Rochdale boundary. An interview has taken place between committees of Heywood and Bury, at which the proposed terms were discussed and a friendly tone prevailed. Apparently there is some hope now that an arrangement will be come to, as both parties seem disposed to take a reasonable view of the position.

**Broughty Ferry.**—An early start is expected to be made with the construction of the Dundee, Broughty Ferry, and District Tramways, which received the Royal assent in August, 1904. Messrs. J. G. White and Co.'s contract includes complete construction and equipment of the permanent way, overhead cars, power-house, car-shed, cables, etc. The price is £68,250. There are 5¼ miles of route, equivalent to 9¾ miles single track. The gauge is standard. The rails are British standard No. 1, 45fc. long, fitted with continuous rail joint and intermediate anchors. The points are 10ft. 6in., having a radius of 100ft. Crossings are iron bound. One mile of the track will run on a new road through the Craigie and Home Estates. This portion of the track will be laid with the usual 6in. bed of concrete and paved with tar macadam and granite edging. The bridge over the Dighty will be widened. The overhead construction will consist mostly of bracket arms. There will be double-trolley wire 2/0 B. & S., height from the ground 21ft. The cables will be laid on the solid system. The power-house will be a brick building, with a chimney shaft of 110ft. The plant will consist of two 200-kw. railway generators with high-speed engines. There will be three Lancashire boilers, superheaters, and usual condensing plant. The car-shed will be a brick building 176ft. long and 45ft. wide. The tracks in the car-shed will consist of Vignoles rails laid on sleepers. There will be 12 single-truck, double-decked cars, fitted with two 37-h.p. motors. The consulting engineer is Mr. J. W. Speight.

**Swansea.**—Major Druitt, on behalf of the Board of Trade, has inspected the permanent way of the company's extension, it being understood that the overhead equipment would be examined a few days later. A considerable party participated in the trial, including Messrs. D. James (manager of the tramways), C. A. L. Prusmann (Corporation electrical engineer), G. Bell (surveyor), Johnson (residential electrical engineer to the company), Gale (permanent-way

Digitized by Google

engineer), J. Foley, Begg, and Schofield (Messrs. Dick, Kerr, and Co.), and Hudson (Messrs. Callender). The car, one of the new type single-deckers, went at a smart rate up High-street, through the Hafod, and thence on to Morriston, where, at the Swan, the course was steered past the church and through Woodfield-street, where the populace were in strong force. At the county boundary line the car retraced its way to the Palace, High-street, thence down Llangyfelach-road, through the Pentre, up to Cwm Level-road, and back to the town. The company have decided to issue transfer tickets on the Sketty and Brynmill section of the new tramway. At a meeting of the Tramways Committee it was reported that the company had returned the draft leases and required the lessors to bear the expense of providing and maintaining the mains between the generating station of the lessors and Villiers-street. This referred to such mains as are necessary to supply the current. The Corporation have agreed to bear the expense of so much of these mains as is necessary to supply the existing tramways of the company from Prince of Wales-road to Morriston, but do not think that they should be called upon to bear the whole expense. The only other point at issue was a proposal by the company to pay ·625 of 1d. per unit for current supplied to the Morriston section until the St. Thomas section is working. The committee were disposed to meet the company in this respect.

**Chester.**—We reported recently that the Tramways Committee had decided to adhere to their recommendation that the electric trams should be extended in lieu of introducing motor 'buses. The Corporation's officials were instructed to present their views on the matter, and these were embodied in reports by Mr. Sydney E. Britton, the electrical engineer; Mr. John Gardner, tramways manager; and Mr. L. M. Jones, city surveyor. Mr. Britton stated that though a certain amount of competition would take place, just as tramways competed with suburban railways, the motor 'bus would no more displace the tramcar than the latter would the railway train. That the motor 'bus had made great strides could not be denied, and there was every reason to believe it would yet be greatly improved upon in the near future; but its field of usefulness was not in the same category as the electric tramcar. Both systems had their special features and ways of catering for the transportation of passengers. British makers of motor 'buses frankly said that 'buses could not compete with, and generally speaking were not intended to deal with, such traffic as the tramcars dealt with. It was beyond their true province of utility. Comparing the two forms of traction, Mr. Britton states: "The two forms of mechanical traction are extensively different, and there can be no doubt as to which is the most reliable, the cheapest to run, and maintain in good repair. On the one hand you have the self-contained motor omnibus carrying its power generator, with multifarious mechaniam and moving parts, consuming practically as much fuel whether running light or at full load; vibrating, whether standing or travelling; and difficult to satisfactorily light. On the other you have the tramcar, with very little mechanism and few moving parts, deriving its energy from a power station as and when required; smooth running, and easily lighted and ventilated. The motor 'bus would show to greater advantage were it merely a question of the smallest capital required to inaugurate a town's system of transportation, but the working expenses are so heavy that it is difficult to see how it can profitably be used in such places as Chester." He estimated that at Chester for the past year motor 'buses would have entailed a loss of £3 000, as against a surplus of £340 earned by the trams. He felt confident that tramways giving a five to ten minutes' service could be worked more efficiently and infinitely cheaper than motor 'buses giving the same service. Mr. Gardner quoted the opinions of Mr. Clifton Robinson and Mr. J. Allen Baker in favour of electric trams, and that of Mr. E. A. Rosenheim, engineer to the Road Carrying Company, Limited, in favour of motor 'buses. It appeared to him that the whole question depended on the volume of traffic. Motor 'buses might pay very well with heavy metropolitan traffic, which was no dependable guide for a small place like Chester. He concluded with the following information: "At Torquay the District Motor Omnibus Company paid for the first year a dividend of 7½ per cent. There the total actual cost on 44,000 miles run was 8·4d. per mile; add 1·5d. for tyres (estimated), and 1·29d. for depreciation (at 10 per cent. per annum), and the revenue 12·68d. per mile. This gives net profit of 1·49d. per car mile. The Eastbourne Corporation motor 'bus department have furnished me with statistics, which show that there the cost of maintenance per car mile for the six months ending Sept. 30, 1904, including capital charges, was 10·4d. The gross income per car mile was 11·3d., which gives net earnings per car mile of 0·9d." If motor 'buses were adopted he suggested either the single-deck type for 18 or 20 passengers, costing £850, or the double-deck 'bus, costing £950. Mr. Jones, who visited the Olympia Motorcar Exhibition, recommended that, should the Corporation decide on motor 'buses, the double-deck type, carrying about 36 passengers in and out, should be adopted as the most suitable for Chester. After summing up the position generally, he returned an "open verdict," saying, in effect, that the question must be decided by the circumstances of the particular district, and that in the case of Chester the motor 'bus was at least worth a second thought. The matter came before the Corporation on Wednesday, when the committee's proposals were confirmed by a large majority.

## LIGHTING AND GENERAL.

**Bristol.**—Sanction has been received to the borrowing of £126,000 for electric lighting.

**Whitby.**—An enquiry has been held into the Urban District Council's application for sanction to borrow £1,500 for electric lighting.

**Glasgow.**—The Guardian Society for the Protection of Trade have agreed to present a petition to Parliament praying that the proposed telephone agreement be not ratified.

**Rawtenstall.**—The Corporation have entered into an agreement, subject to the approval of the Board of Trade, to take current from the Lancashire Electric Power Company for a period of five years.

**Bury.**—The borough electrical engineer (Mr. S. J. Watson) in his last report stated that he anticipated that after all expenses and charges had been met there would be a profit on the electricity works for the past year of about £3,000.

**Horsham.**—The Urban District Council have now 8,375 electric lamps connected with their system. It has become necessary to considerably increase the machinery plant in order to cope with the demands of new subscribers.

**South London Electric Supply Co.**—The company reports having sold during the quarter ended Lady Day last 2,457,880 units, realising £20,640. The figures for the corresponding quarter in 1904 were 2,120,539 units realising £18,600.

**Stock Exchange.**—Application has been made to the Stock Exchange Committee to allow the Electric Lighting and Traction Company of Australia further issue of £70,000 5 per cent. first debenture stock to be quoted in the official list.

**Woolwich.**—The cost of the erection of the electricity sub-station in Eltham-road, Lee, is estimated at £450, and that in Red Lion-lane, Shooters' Hill, at £740. This work is to be carried out by direct labour, under the supervision of the borough engineer.

**St. James's and Pall Mall Electric Light Co.**—The current sold during the quarter ended Lady Day, 1905, totalled 2,332,361 units, estimated to produce £34,985, as against 2,330,724 units, which produced £35,320, for the corresponding period of last year.

**Faversham.**—The Town Council have resolved to extend the electric supply cables into three new roads at present unlighted at a cost of £357 for the private service and £205 for the public service. The engineers are to obtain orders for the required supplies.

**Fire.**—We regret to learn that a large amount of damage has been done by a fire at the Morley Electrical Engineering Company's works at Stanningley. Patterns and drawings were destroyed, and dynamos and motors were drenched with water. The premises were insured.

**Brush Electrical Engineering Co.**—The directors recommend, subject to audit, payment of the full 6 per cent. dividend on the preference shares for the year ended Dec. 31, 1904, placing £7,000 to general reserve, £6,500 to depreciation reserve, and carrying forward £3,080.

**Southwark.**—The Borough Council are not out of the wood yet with regard to their electric light undertaking. At Wednesday's meeting notice was given of a resolution to sell the electric light undertaking as a going concern, in view of its heavy cost to the ratepayers.

**Torquay.**—The Local Government Board have suggested to the Town Council that, instead of spending £42 000 on a new electrical station, an endeavour should be made to utilise the existing station for six or seven years longer. In this case the current for the proposed trams would have to be provided by a company.

**Electric Pumping.**—The Electrical Company, Limited, 121-125, Charing Cross-road, have just completed the supply of a high-tension electrical pumping plant, with high-lift centrifugal pumps, at Messrs. Bolckow, Vaughan, and Co.'s, Limited, Shildon Lodge Pit. This plant is of special interest, being the largest of its kind installed in England.

**Stirling.**—The report of Mr. A. C. Hanson, electrical engineer, for the four weeks ending March 18 shows that 22,946 units have been generated, as compared with 20,236 for the corresponding period last year. The total number of equivalent 8-c.p. lamps connected for all purposes is 16,549, as compared with 14,110 at the corresponding date last year.

**Penrith.**—A letter from Messrs. J. and J. Enright, asking if the Urban District Council would be prepared to consider the transfer of the electric lighting provisional order on the understanding that the cost of the order would be refunded and the Council to have opportunity of purchasing the undertaking from time to time, is before the General Purposes Committee.

**Dunfermline.**—On Wednesday the Town Council discussed reports by Mr. W. B. Sayers, electrical engineer, Glasgow; Mr. Alexander Waddell, gas manager, Dunfermline; and Mr. Nigel H. Cohen, electrical engineer, London, on schemes for the provision of electric energy and light for the burgh. Eventually it was agreed to adjourn consideration of the reports and proposals.

**Telegrams.**—The Postmaster-General has stated that there is at present no likelihood of any reduction being made in the charges for inland and foreign telegrams. It appears that while it is not at present proposed to introduce the cash-on-delivery system in the United Kingdom, the question of introducing it between England and the British Colonies and possessions and Egypt is under consideration.

**Fraserburgh.**—A committee has been appointed to consider a letter of the Pneumatic Tool Company asking if the Town Council would require any electric current before the company quoted for supplying the harbour and railway authorities. If the Council required it, the company would take it into consideration in laying their cables. The Town Council may probably adopt electric lighting for one or two of the main thoroughfares.

**Longton.**—The Corporation Gas and Electricity Committee have made the following reduced rate at which current will be supplied for electric motors: for 500 units per quarter or less, 2½d. per unit; above 500 units, and under 1,000, 2¼d. per unit; above 1 000 units, and under 1,500, 2d. per unit; above 1,500 units, and under 2,000, 1¾d. per unit. The price paid by consumers of electricity for lighting purposes last year averaged 4¼d. per unit, a price which is cheaper than lighting by gas.

Digitized by Google

**Exeter.**—The electrical engineer, in his last report, states that during the 12 months' working now completed there has been no failure of supply due to defects in the machinery at the new generating station. The tramway generators are particularly satisfactory in work. A sub-committee has been appointed to consider the question of the Council supplying motors on the hire-purchase system. It is proposed to erect a wood fence and gates at the power station at an estimated cost of £300.

**Wisbech.**—The Town Council have been informed, with regard to their electric lighting order, that certain questions having arisen with regard to the powers of local authorities to enter into contracts under Section 11 of the Electric Lighting Act, 1882, in which the Board have found it necessary to seek the opinion of the law officers of the Crown, the Board are unable to give a decision on the matters which have been referred to them by the Local Government Board until that opinion has been received.

**Brockenhurst.**—The Board of Trade have issued a provisional order with a view to the same being included in a Confirmation Bill, about to be introduced into Parliament, to Messrs. Christy Bros. and Middleton, of Chelmsford, authorising them to transfer the powers granted by the Brockenhurst order to a registered company to supply electrical energy for both public and private purposes within so much of the parish of Brockenhurst in the rural district of Lymington as is described in the first schedule to the said order.

**Underground Telegraphs.**—Satisfactory progress has been made during the past two months with laying the underground telegraph to the North, and the permanent cable will probably be ready for opening in a month or two. The permanent cable has been completed between London and Warrington, Warrington and Liverpool, and Warrington and Manchester. A temporary cable has been drawn into the pipes between Manchester, Leeds, and Bradford. The permanent cable has also been drawn in between Warrington and Carlisle *via* Preston, but that section of the work is not yet finished. The pipe line from London to Glasgow was completed a few weeks ago, except a small section on which the work was interrupted owing to a dispute with the road authorities.

**Dundee.**—At the last meeting of the Tramways Committee Mr. Richardson, the engineer, reported that he anticipated that next winter the Corporation electricity department would have to meet a maximum load of about 2,000 kw. There was only available plant of 2,300 kw. capacity to meet this demand, and the load on the outlying points had grown so rapidly that the long feeders to these districts would require to be considerably enlarged. Increased requests were coming in from parts at the extremities of the area for power and lighting, but these points were so far away from the station that it was both uneconomical and dangerous to try to connect them up to the present low-tension station. The committee have instructed the engineer to prepare a detailed report and alternative schemes, and as to the general policy of extension.

**London Gazette.**—The last day for receiving proofs in the estate of Arthur Edgar Brooks, electrical engineer, 110, Cheapside, London, is May 10. Arthur Stewart Maples, Trinity House-lane, Hull, has been released from trusteeship in the estate of Charles Wallis, electrical engineer, 121, Cleethorpes-road, Great Grimsby. Thomas Henry Peake, 6, Athenæum-terrace, Plymouth, has been released from trusteeship in the estate of Samuel Henry Thompson and James Edgar Thompson, electricians, trading as Thompson Bros. and Co. at Plymouth. The partnership between Charles Herbert Offord and Frank Clemens Wilson, carrying on business as electrical engineers at Woodcock-street, Birmingham, has been dissolved by mutual consent. A receiving order has been made out on creditors' petition in the estate of Arthur Driffell Poulter, printers' and electrical engineer, New Bridge-street, London, E.C.

**Dover.**—The Board of Trade have issued a provisional order with a view to the same being included in a Confirmation Bill about to be introduced into Parliament to the Corporation of Dover authorising them to supply electrical energy for all public and private purposes within the parishes of River Ewell, Whitfield, St. Margaret's-at-Cliffe, West Cliffe, and Guston in the rural district of Dover, and so much of the parish of Alkham in the said rural district as lies to the east of a line drawn from the south-eastern boundary of that parish at the junction of Minnis-lane and Abbey-road in a northerly direction to the road leading to Ewell Minnis at the point where the north-eastern boundary of the parish running in a south-easterly direction meets the said road. A proposal to light Folkestone-road by electric arc lamps at an increased cost of £165 was discussed at the last Council meeting, and a recommendation to light half the road in this manner as a test was carried.

**Ferranti Limited.**—A scheme of reconstruction has now been carried through, and the new company, "Ferranti Limited," has been registered. The directors and principal officials of the new company are as follows: directors—A. W. Tait, chairman (director of Messrs. Bruce Peebles and Co., Limited), Arthur Whittaker, J. M. Henderson (director of Messrs. Thos. Bolton and Sons, Limited), S. Z. de Ferranti, M.I.M.E., M.I.E.E., M.I.C.E.; general manager—A. B. Anderson; chief engineering staff—Michael B. Field, M.I.E.E., A.M.I.C.E., A.M.I.E.E. (America), W. Hamilton, B.Sc., W.Sch., C. C. Garrard, Ph.D., A.M.I.E.E. The business of the company will henceforth be confined to the manufacture of switchgear (with all necessary accessories), transformers, instruments, and meters; but in order to meet the convenience of the customers of the old company, arrangements have been made for dealing with the maintenance and repair of engines and alternators supplied by them.

**Cardiff.**—Mr. Arthur Ellis, the electrical engineer and manager, in his last report states that there are now 1,128 consumers whose premises are connected with the mains, with a total equivalent of 129,362 8-c.p. lamps, as against a total of 109,570 at the corresponding period last year. The estimated revenue was as follows; revenue from street-lighting, £595. 16s. 6d.; from private supply, £2,294. 8s. 4d.—making a total of £2 890. 4s. 10d. The estimated revenue for the corresponding month of last year was £2,576. Mr. Ellis reported the new sub-station at the docks is now completed, and we understand supply to the docks from the new sub-station has been commenced. The sub-station has been fitted up in such a way that the docks district can be entirely disconnected from the town, or, in the case of an accident, the docks sub-station can assist the town lighting by means of a battery which has been installed.

**Croydon.**—The following resolution has been carried: "That, having regard to the heavy expenditure involved in the present mode of lighting the borough, the Lighting and Electricity Committee be requested carefully to consider the matter, and to make such suggestions to the Council as may tend to a considerable reduction in the cost of street-lighting." During the year 1904 the Council have paid to the Croydon Gas Company and the Crystal Palace Gas Company for street-lighting £7,065, and for electric light £7,357, making a total of £14,423. There are 2,131 gas lamps, and 2,614 electric lamps. During the last 10 years the cost of the public lighting has greatly increased. In 1894 the total cost was £6,590, and in 1904 it was £14,423. In 1894 the lighting rate was 3d. in the £, and now it is 4½d., and 1d. in the £ on the district rate now amounts to £3 500. This is, of course, mainly due to the growth of Croydon during this time; in 1894 there were 132 miles of streets, and there are now 150½ miles.

**Edinburgh.**—An exhibition of a working model and full-sized section of the Dolter electric surface-contact system was opened at 100, George-street last week. The Electric Lighting Committee estimate that the ordinary expenditure for the year from May 15 will be £53,890 against the estimated expenditure of £49,265 last year, and an actual expenditure last year of £43,129. The revenue was estimated at £128,705 against the actual revenue last year of £116,178, and an estimate of £117,310. The sum for capital expenditure is estimated at £48,820. The committee have agreed to recommend that the charges for electric energy during the year from May 15 be as follows: for private lighting, 3½d. per unit; for motor power, 1½d. per unit; for the present public lamps, £10. 15s. per lamp; and for new public lamps, £10 per lamp. The committee agreed to recommend that a special charge of 1$\frac{1}{10}$d. per unit be made for consumers for motor power not using motors during the four winter months when the lighting is heaviest—November, December, January, and February.

**Stepney.**—The annual report of the Borough Council's Electricity Committee shows a gross profit of over 6¾ per cent. on the capital employed at the end of the year. After providing for interest, sinking fund, and other charges, a net profit of 2¾ per cent. has been made. The committee point out also that this profit has been earned in spite of additional charges for reduction in price to consumers, £2,300; interest, £1,208; sinking fund, £1,126; the net surplus being only £91 less than that of last year, although the revenue per unit has dropped from 2·36d. to 2·11d., a figure below that charged by any other undertaking (not supplying tramways) in the country. The charge for public lighting current has also been reduced to 1·55d. from 1·61d. This figure is also claimed to be lower than that of any other undertaking in London. On the expenditure side the cost of production has been reduced from ·94d. to ·85d. per unit sold, while the total cost, exclusive of interest and sinking fund, is 1·10d. per unit, which is also a reduction on the previous year.

**Luton.**—An enquiry has been held into the Town Council's application for sanction to borrow £5,000 for extension of the electric light works. The Town Clerk said the population was estimated at 38,500, and the total amount of outstanding loans was £116,106. The assessable value was about £162,000, and a penny rate produced £650. The poor rate in the past three years had been 3s. 3d. and 3s. 6d., the Corporation's district rate being 2s. 6d., and the borough rate 8d. last year. Mr. G. Sell, the electrical engineer, stated that the extension of the plant was absolutely necessary to supply next winter's demand. The total capital expenditure on the electricity works up to date was £32,000. The number of units sold increased from 160,844 to 276,458 in the last two years, the consumers from 154 to 235, lamps connected from 10,535 to 14,425, motors from 160 h.p. to 327 h.p. The present capacity of the works was 297 kw., and there were two Lancashire boilers. They proposed to add another boiler and a 225-kw. set. We understand that the Council expect next year to apply for another £7,000 for further extensions.

**Chester.**—The Lighting Committee have recommended to the Town Council as follows: That (1) the present charge of 4½d. per unit, with discounts, for current lighting be reduced to 4d. per unit, and that the discounts remain unaltered, and that the reduction take effect from June 30 next; (2) for all classes of meters a fixed charge of 1s. per quarter for each meter be made, to take effect from June 30 next; (3) under the powers conferred by Section 78 of the Chester Corporation Act, 1901, the Corporation provide and sell to consumers and contractors incandescent and Nernst lamps; (4) the uses to which electricity can be put, and the willingness of the department to give advice free of charge, be advertised in the local newspapers and by circulars, and that it be referred to the town clerk and the electrical engineer to prepare, from time to time, draft advertisement and circulars, with estimates of the cost, and submit them to the committee for approval; (5) the electrical engineer prepare and issue a model specification and schedule dealing with wiring work, stating the quality of the materials and the way in which the work should be executed; (6) the committee be authorised to rent and fit up a room in a central position in the city, wherein to exhibit and demonstrate the most improved and up-to-date electrical appliances, such as fittings, lamps, motors, stoves, ovens, kettles, pans, irons, and other heating and cooking apparatus, to be lent by manufacturers of these appliances; (7) an exhibition of all kinds of electrical appliances be held in the Assembly Room at the town hall for about 10 days in September next.

Digitized by Google

**Manchester Exhibition.**—An exhibition and demonstration of motor vehicles and electric and pneumatic appliances is to be held from May 2 to 5, from 10 a.m. to 6 p.m., at the Key Engineering Company's showrooms, Scottish Insurance-buildings, 33, Deansgate, Manchester. The exhibits will comprise J. I. Thornycroft and Co.'s steam wagon, touring car, cylinder launch engine, etc.; Elliott Bros.' new patent moving-coil ammeters and voltmeters for direct and alternating currents and other instruments; Cowans, Limited, high-tension oil-brake mechanically-operated switch panel, equipped with Andrews patent discriminating cut-out and current direction indicator (in operation), motor starter, etc.; Witting, Eborall, and Co., Limited, reversible controller and a Heyland single-phase alternating-current motor with special starting switch for same. The Fibre Conduit Company will exhibit specimens of screwed and socketed conduits for electric cables and other purposes. There will be also a Reavell patent 60 cubic feet electrically-driven air-compressor and a pneumatic hoist (in operation). The Industrial Engineering Company will show patent valveless pneumatic hammers, rivetters, caulking tools, electric motors, etc. A demonstration will be given of the Harris combined chemical and mechanical process of removing oil and other impurities from condensed water. Other exhibitors will be the Delafon Batteries Company, Limited, the Reason Manufacturing Company, Limited, the Otis Elevator Company, Limited, the Phœnix Art Metal Engineering Company, the Bat Meter Company, Crosier, Stephens, and Co., and the T.P. Ford Company. A special day is to be set aside for a visit of electrical engineers. The Key Engineering Company are introducing a new conduit for electric cables. A considerable portion of 34 miles of this conduit has already been laid in Manchester, and Mr. Pearce, the Corporation electrical engineer, has arranged to lay some during next week.

**Greenock.**—At the last meeting of the Corporation the electrical engineer reported on the supply of electricity to the new combination hospital at Gateside that, the distance from the Corporation generating station to the hospital being 2,750 yards, in order to ensure constant pressure of supply under all conditions at this distance it would be necessary to run the cables direct from the works to the hospital. If a three-way system of cables be laid to give current at the same pressure as it was supplied in Greenock, the cables being of sufficient capacity to supply the equivalent of 1,600 lamps of 16 c.p., the capital cost would amount to £1,850. As it was probable, however, that a supply would also be required for Smithston Institution within the next few years, it would be advisable to lay a cable of sufficient size to supply current to this institution also, at an additional cost of £400, or say, a total of £2,250. He estimated that the average consumption of electricity by the hospital would amount to about 38,000 units per annum. If the supply was given at the ordinary rates, the system under which the current would be charged for would be method C—*i.e.*, maximum demand system. Under this system the average price to the hospital would probably amount to not more than 3d. per unit, and on this basis the income to the Corporation would be £475 per annum. He was of opinion that, in order to properly safeguard the interests of the Corporation, it would be necessary for the hospital authorities to enter into a contract with the Corporation for a period of not less than 10 years, to use or pay for electricity of a value at the above rates of not less than £400 per annum. The report was adopted, and it was decided to purchase a new generating set and a storage battery. The Corporation some time ago decided to adopt a scheme of free wiring to induce customers for electricity, and there are now so many applicants that the committee can select whom they think most desirable. During the last three months more electric lamps have been connected in Greenock than during the previous year.

**Blackpool.**—In his last monthly report, Mr. C. Furness, the borough electrical engineer, estimates that there will be an available balance from his department of approximately £5,000 towards the reduction of the rates. There is a large increase in the tramway receipts, amounting to £6,469, from April 1, 1904, to March 31, 1905, as compared with the corresponding period in 1903-4. The returns for the month of March showed a net increase in the works output over the corresponding month of last year of 16,445 units, made up as follows: Private lighting: 1904, 79,564; 1905, 75,027—decrease, 4,537. Public lighting: 1904, 14,711; 1905, 14,034—decrease, 677. Lytham and St. Annes trams: 1904, 9,892; 1905 4,466—decrease, 5,426. Corporation tramways: 1904, 72,748; 1905, 99,833—increase, 27,085. Total for month: 1904, 176,915; 1905, 193,360—net increase, 16,445. The total works output for year ending March 31 shows an increase of 257,967 units over last year. The figures are as under: Private lighting: 1904, 1,052,440; 1905, 1,086,272—increase 33,832. Public lighting: 1904, 231,296; 1905, 248 916—increase 17,620. Corporation tramways: 1904, 1,009,015; 1905 1,110,082—increase, 101,067. Lytham and St. Annes trams: 1904, 93,063; 1905, 115,763—increase, 22,700. Used on works: 1904, 39,569; 1905, 114,219—increase, 74,650. Losses, etc: 1904, 145,507; 1905, 153,665—increase, 8,098. Totals for year: 1904, 2,570,890; 1905, 2,828,857—increase, 257,967. New consumers in 1905, 55; against 68 in 1904. Mr. Furness points out that there has been a decrease in private lighting for the month of March of 4,537 units as compared with the corresponding month of last year, and he trusted that the revised charges recommended would be adopted at an early date. There has been a big reduction in the consumption of coal during the past year, as will be seen from the following figures: 1902, 15,289 tons, £7,867; 1903, 15,000 tons, £7,319; 1904, 14,869 tons, £7,202; 1905, 10,869 tons, £4,946. In the concluding paragraph of his satisfactory report Mr. Furness says: "Comparing the years 1902-3 and 1904-5, the coal saving represents £2,921, whilst, on the other hand, the works output has increased by no less than 566,000 units, or 25 per cent., and I anticipate that after meeting all loan charges and sinking fund, etc., we still shall have an available balance of approximately £5,000."

**Reading.**—An electrical exhibition, with which we deal in another column, was opened in the Exhibition buildings, Vastern-road, Reading, on Monday, and will remain open until Saturday, April 29, from 11 a.m. to 10 p.m. each day. The Reading Electric Supply Company have hired one of Edmundson's travelling exhibitions *en bloc* to form a nucleus, and have secured the co-operation of about 30 private exhibitors as well, among the firms occupying stands being J. S. Henry, Limited; Saunders's Launch Building Company, Limited; Vernon, Davenport, and Co., Limited; Industrial Battery Syndicate; Harper's Automatic Company; Simplex Conduit Company; Waygoods, Limited; Reason Company; Broom and Wade; Windsor Electric Company; Isometric Lens Company; Botley and Lewis; S. Griffith; W. H. Baugham and Co.; Verity's, Limited; Singer Manufacturing Company; A. E. Felgate; Hawkes and Sons. The company's own machinery room forms an annexe to the exhibition. The following reduced rates for the supply of electrical energy will come into force on July 2 next: For lighting purposes (supplied at 200 volts)—to consumers using 1,000 units and under during the half-year ending June 30 or Dec. 31, 6d. per unit, with a minimum charge per quarter of 5s.; to consumers using more than 1,000 units, but not exceeding 2,500 units, during the half-year, 5d.; to consumers using more than 2,500 units, but not exceeding 5,000 units, during the half-year, 4½d.; to consumers using more than 5,000 units, but not exceeding 7,500 units, during the half-year, 4d.; to consumers using more than 7,500 units, but not exceeding 10,000 units, during the half-year, 3½d.; to consumers using more than 10,000 units during the half-year, 3d. Meters supplied free. Special rate for basement lighting by separate meter, for which a rental of 3s. 6d. per quarter will be made, 3d. For motive power—for all demands up to and including 4 b.h.p., supplied at 200 volts direct current, 2d. (a minimum charge of 7s. 6d. per quarter will be made, which will include a meter rental of 3s. 6d.); for all demands above 4 b.h.p., supplied at 200 or 400 volts direct current at the company's option, 1½d. (a minimum charge of 10s. per quarter will be made, which will include a meter rental of 3s. 6d.). For heating, etc.—for all demands, 1½d. (a minimum charge of 5s. per quarter will be made, but no charge will be made for the use of meter). Also special terms will be quoted on application for installations requiring a long hour supply.

**Islington.**—The borough treasurer has prepared the following statement with regard to income tax: Income from all sources, £48,436; deduct income derived from street-lighting, £15,647—£32,789. Expenditure, £47,309; deduct expenditure in respect of street-lighting, £11,623; interest on loans, £12,180; repayment of loans, £6,173; income tax, £706; interest on deposits, £13—£16,614. Taxable income, £16,175. Three years' average amounted to £15,057; deduct amount allowed for depreciation on capital expended on boilers and machinery, electrical instruments, transformers, etc., £2,474—total, £12,583. Reporting on this statement the Finance Committee say: "Income tax at 1s. in the £ on this sum amounts to £629. 3s. There is, however, a substantial set-off against this charge in the amount of income tax deducted by the Council from interest on loans raised for the electricity undertaking. In a recent decision of the House of Lords in the case of the Attorney-General *v.* the London County Council, it was held that where the interest on the loans is paid out of profits the person who makes the payments and deducts the income tax is not accountable to the Crown for the duty deducted. The figures for the current year are not available, but we may mention that last year the amount of income tax deducted from interest on loans was £393. 16s. 3d. We are satisfied that the amount of £629. 3s. is properly payable, and we have accordingly included it in our list of proposed payments." In consequence of an application from the Westinghouse Brake Company for an additional supply of electricity to their premises in York-road, additional mains are to be laid and two transformers procured at a total cost of £390. An additional extension is to be made at a cost of £76. The electrical engineer has reported to the effect that an extension of generating plant is required, and the committee find that the present total capacity of the works is approximately 3,600 kw., and that the maximum load demanded during the past winter was approximately 2,400 kw., leaving a reserve of 1,200 kw. Islington at the peak of the load last winter had only a reserve of 33 per cent. The committee say that since the maximum load of last year was attained an equivalent of 5,000 lamps, or about 150 kw., has been connected, in addition to which they have recently received an application for an extension for supply to the Post Office premises in Upper street of 250 kw. Assuming that half of the 5,000 lamps mentioned are running at one time, there would be considerably over 300 kw. to add to the peak of the load next winter, apart from any other connections that may be made in the meantime, leaving with the present plant a bare 25 per cent. reserve. As it had taken in the past some 12 months to get plant into commission, they think that it would be running a serious risk to delay the extensions any further. They recommend the following expenditure: one 1,500-kw. turbo-alternator, including turbine, alternator, exciter, condenser, pumps, etc., £9,000; foundations for above, £250; steam-pipes, hot feed apparatus, etc., £1,500; one cooling tower capable of dealing with water for above, £3,750; motors, fans, piping, etc., £500; contingencies, £500—total, £15,500. The electrical engineer has reported as follows: "The 1,500 kw. turbine proposed would run the bulk of the evening load, and would in any case be practically fully loaded for about four hours every day. This would mean an output of about 6,000 units on this machine alone. As the majority of makers are prepared to guarantee a consumption of between 18lb. and 20lb. of steam per unit generated against an average of 35lb. of steam per unit generated consumed by the existing non-condensing plant, it will be seen that about 40 per cent. of the steam hitherto used to run the above section of load—viz., 6,000 units—would be saved, and as steam, even when generated by mechanical stokers, would cost 6d. per 1,000lb., it will be seen that if we assume a consumption of 20lb. of steam per unit

Digitized by Google

for 6,000 units, which is a reasonable figure for turbines, and we assume 35lb. of steam per unit for the section of 6,000 units with the existing plant, we should effect, by the use of the turbo-generator, a saving each evening of 90,000lb. of steam, or representing in value at 6d. per 1,000lb. £2. 5s. To allow for the necessary cleaning of the plant, and machine being out of commission for other causes, it would be advisable to assume a weekly run to consist of five days. This would mean a saving of £11. 5s. per week in reduced steam consumption, or sufficient to pay the interest and redemption charges on the cost of the turbo, say £9,000. The charges on the new turbo would therefore be entirely paid for by the economies effected, and the department would therefore have the advantage of an additional revenue-earning machine without extra cost. The cooling tower estimated for will be more than sufficient to provide circulating water for the turbine, and the additional capacity will be utilised for an extension of our present condensing system, thereby effecting a reduction in the coal bill of some £300." The committee are of opinion that when the new plant has been running for 12 months there will be a marked difference in the cost of production.

## PROVISIONAL PATENTS, 1905.

APRIL 11.

**7645. Improvements in electrical transformers and the like.** Gordon Hanchett, 4, St. Ann's-square, Manchester.

**7700. Improvements in magneto-electric machines.** Edward Benthall Gray, 6, Bream's-buildings, Chancery-lane, London.

**7707. Improvements in lifting magnets.** Arthur Clarke Eastwood, 47, Lincoln's-inn-fields, London. (Complete specification.

**7720. Improvements in the manufacture of electric accumulators.** Henry Leitner, 4, South-street, Finsbury, London.

**7721. Improvements relating to electric single-phase motors.** The Phœnix Dynamo Manufacturing Company, Limited, and Wilhelm Oelschläger, 322, High Holborn, London.

**7732. New or improved means for electrically indicating and recording at a distance changes in level of liquid in reservoirs and for giving warning of any prearranged maximum or minimum level.** Paul Virgile Vaudrey, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents Act, 1901, April 11, 1904, being date of application in France.) (Complete specification.)

APRIL 12.

**7814. Improvements in appliances for lighting gas lamps and the like by electricity.** William Phillips Thompson, 6, Lord-street, Liverpool. (Oscar Freudenthal, Belgium.)

**7819. Improvements in coil-winding machines.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (General Electric Company, United States.)

**7822. Improvements in systems of control for electric motors and apparatus therefor.** The British Thomson-Houston Company, Limited, 83 Cannon-street, London. (General Electric Company, United States.)

**7841. Improvements in and relating to telegraphic system and to apparatus therefor.** Walter Polk Phillips, 7, Southampton-buildings, Chancery-lane, London. (Complete specification.)

**7842. Improvements in flexible armoured electric cables.** Walter Claude Johnson and Sydney Paterson, Norfolk House, Norfolk-street, Strand, London.

**7843. Improvements in electric arc lamps.** Leon Galas, 18 Buckingham-street, London.

APRIL 13.

**7856. Improvements in or connected with electrically-propelled railway vehicles or locomotives.** John Paul Barker, 15, Water-street, Liverpool.

**7872. Improvements in magneto-ignition devices.** Edward Russell Clarke, 35, Leinster-gardens, Hyde Park, London.

**7874. Improvements in and relating to apparatus for the control of electric circuit breakers and like devices.** Leonard Andrews, 38, Deansgate, Manchester. (Complete specification.)

**7879. Improvements relating to trolley heads in connection with overhead electric transmission.** Joseph Wyatt Handcock, 17, Belvoir-street, Leicester.

**7892. Improvements in vapour electric apparatus.** Percy Holbrook Thomas, the Westinghouse Patent Bureau, Westinghouse-building, Norfolk-street, Strand, London. (Date applied for under Patents Act, 1901, April 14, 1904, being date of application in United States.) (Complete specification.)

**7903. Improvements in electric accumulators or secondary electrolytic cells.** William Fennell and William Pagden Perry, 33, Cannon-street, London.

**7919. Improvements in and relating to electric rheostats.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

**7920. Improvements in electric switches.** Sherard Osborn Cowper-Coles, 4, South-street, Finsbury, London.

APRIL 14.

**7956. Improvements in lifeguards for electrically-propelled vehicles and the like.** Edgar Ashley Greaves, 9, Tempest Hey, Liverpool.

**7987. Improvements relating to adjustable brackets or arms for supporting electric lights or the like, and applicable also to brackets or supports for other purposes.** William Henry Pick, trading as Collins and Co., 43, King-street, Leicester.

**7972. Improvements in or relating to electrical regulating, testing, and measuring apparatus.** Robert William Paul and George William Harris, Newton Avenue Works, New Southgate, London.

**8002. Improved construction of apparatus for winding coils and bobbins for electrical and other purposes.** Harry Bourne, 175, Fleet-street, London.

**8026. Improvements in starting devices for alternating-current dynamo-electric machines.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

**8027. Improvements in block signal systems for railways.** The British Thomson-Houston Company, Limited, London. (The General Electric Company, United States.)

**8028. Improvements in electric motor-controlling switches.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

**8033. Improvements in terminals and connections for electric wires.** Alan John Downes, 412, Munton-road, New Kent-road, London.

APRIL 15.

**8049. Improvements in and relating to the working of electric or other tramway or railway points.** Wilfred Bruce Docharty, 96, Buchanan-street, Glasgow.

**8051. Improvements in and relating to electrical circuit breakers.** Veritys, Limited, and Arthur Edgar Gott, 11, Burlington-chambers, New-street, Birmingham.

**8071. Improvements in automatic electric circuit breakers.** James Ernest Spagnoletti, Palace-chambers, Westminster, London.

**8090. Improvements in and relating to trolleys for electric railways and the like.** Arnaldo Paolo Zani, 18, Southampton-buildings, Chancery-lane, London. (Complete specification.)

**8095. Improvements in and relating to electric switch mechanism.** The British Thomson-Houston Company, Limited, and Frank Holden, 83, Cannon-street, London.

APRIL 17.

**8122. Improvements in the construction of electric tramways.** Samuel Green Bennett, Clyde House, Heath Town, Wolverhampton, Staffs.

**8127. Gasproof disconnecting plug for electrical switches.** Albert Ernest Carter, 6, Gardner-street, Brighton, Sussex.

**8168. Improvements in and relating to electric telegraph apparatus and in particular to devices for indicating at a distance the position of a pointer, needle, or the like.** Hans Usener, Thanet House, Temple Bar, London. (Complete specification.)

**8190. Improvements relating to electric batteries.** Henry Harris Lake, 7, Southampton-buildings, Chancery-lane, London. (La Société Anonyme le Carbone, France.)

**8198. Improvements in or relating to multiple-unit control for electric motors.** Thomas Steel Perkins and Ray Philip Jackson, The Westinghouse Patent Bureau, Westinghouse Building, Norfolk-street, Strand, London. (Date applied for under Patents Act, 1901, June 6, 1904, being date of application in United States.) (Complete specification.)

**8200. Improvements relating to the transmission of electrical energy.** Henry Harris Lake, 7, Southampton-buildings, Chancery-lane, London. (Nikola Tesla, United States.) (Complete specification.)

APRIL 18.

**8215. Improvements in the regulation of the voltage of alternating electric current systems and in apparatus therefor.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

**8253. Electric light hanger for walls.** Willy Harz Lau, 65, Chancery-lane, London. (Date applied for under Patents Act, 1901, April 23, 1904, being date of application in United States.) (Complete specification.)

**8267. Improvements in and means for electrically recording weights lifted by a crane or the like.** Charles Russo and Edward Caro Feinstein, 33, Chancery-lane, London.

**8278. Improvements in electrical switches.** Walter S. Mayer, 7, Southampton-buildings, Chancery-lane, London. (Complete specification.)

**8305. Improvements relating to electric wiring and controlling systems.** Alfred Blackmore, 322, High Holborn, London.

## COMPLETE SPECIFICATIONS ACCEPTED.

*To be published May 4.*

1904.

**14087. Box or cell and lid for electric accumulators on board ships, motorcars, and the like.** Smethurst and Bishop.

Digitized by Google

**13180. Electric radiaters.** Dowsing[1]

**20351. System and apparatus for electrically operating bulkhead doors, hatches, or the like.** Jones. (Long Arm System Company.

**20536. Bath for therapeutic treatment by means of electric and other forms of radiant energy.** Smyth.

**23012. Enclosed dynamo-electric machines.** Newbold. (Date applied for under International Convention, Nov. 3, 1903.)

1905.

**47. Magnetic compasses.** Wilke.

**315. Plates for secondary batteries.** Thompson. (Pflüger Accumulatoren-Werke Act.-Ges.)

**1378. Telephony.** Buell.

*To be published May 11.*

1904.

**9190. Arc lamp electrodes.** Weedon. (Date applied for under International Convention, April 21, 1903.)

**10459. Electric control systems.** British Thomson-Houston Company, Limited. (General Electric Company.)

**10672. Gas or vapour electric apparatus.** Le Tall. (Cooper Hewitt Electric Company.)

**10962. Electromagnetic apparatus for operating railway signals and points.** Timmis.

**11093. Electric meters.** Atkinson.

**11284. Counterweights for electric light fittings and the like.** Hirst and Collings.

**11633. Electromagnetic selecting or distributing device for use in type-distributing and other machines.** Wagner.

**11842. Apparatus for lighting railway vehicles by electricity.** Wright.

**12136. Manufacture of welded conduits for electric wiring.** Taylor.

**12214. Electrical cooking and heating apparatus.** British Prometheus Company, Limited, and Skipwith.

**12418. Electric switches.** De Veulle.

**13072. Electric condensers.** British Thomson-Houston Company, Limited. (General Electric Company.)

**13277. Coil-winding apparatus for electrical purposes.** British Thomson-Houston Company, Limited. (General Electric Company.)

**13516. Mechanical ear, used for the suspension of overhead trolley wire.** Taylor.

**13569. Electric controllers.** British Thomson-Houston Company, Limited. (General Electric Company.)

**13596. Electric alarm clocks.** Baynes.

**13686. Clocks controlled by reversals of electric current.** Howorth. (Firm Magneta, Fabrik Electrischer Uhren.)

**13720. Electrical traction overhead conductor equipment.** Schierwater.

**13864. Construction of dynamo-electric machines.** British Thomson-Houston Company, Limited. (Allgemeine Elektricitäts-Ges.)

**14128. Method of preliminary treatment for electric accumulator plates.** Leitner.

**14196. Electrodes for arc lighting.** British Thomson-Houston Company, Limited. (General Electric Company.)

**15294. Process of electrodepositing antimony.** Betts.

**22808. Alternating-current electric motors.** Lundell.

**25619. Wireless telegraphy.** Howorth. (Squier.)

**27982. Secondary batteries.** Gardiner.

**28370. Electric switches.** Harrison. (Guett.)

1905.

**352. Protective apparatus for alternating-current circuits.** Davis and Conrad. (Date applied for under International Convention, Jan. 20, 1904.)

**2266. Construction of spring jacks for telephone switchboards.** Siemens Bros. and Co., Limited. (Siemens und Halske Act.-Ges.)

**4832. Electrical fittings.** Dugdill.

**6865. Micro-telephones or instruments containing a telephonic receiver and transmitter in one casing.** Birnbaum. (Telephon Fabrik Akt.-Ges. vorm. J. Berliner.)

## NOTES.

**The Electrical Engineers (R.E.V.).**—The Electrical Volunteers are holding a regimental Bohemian concert at the Caxton Hall to-morrow night, this being the last of the season. The chair will be taken by Colonel Crompton at 8 p.m.

**The American Institute.**—We have received a copy of this institute's *Proceedings* for April, the contents of which include papers on "Polyphase Metering," by D. J. Nies; "The Use of Instruments on Switchboards," by F. P. Cox; "The Oscillograph and its Uses," by L. T. Robinson; "Maintenance of Meters," by W. J. Mowbray; and "Cement in Central-Station Design," by E. B. Clark; also the discussions on "Two-Motor *versus* Four-Motor Equipments" and "Track Bonding."

**Personal.**—The council of the City and Guilds of London Institute have conferred the fellowship of the institute on Mr. H. Cecil Booth in recognition of the original and valuable engineering work which he has done since he gained his diploma of associate of the City and Guilds Institute in 1892. Since Mr. Booth left the institute's Central Technical College he has been engaged in many branches of engineering work, and is the inventor of the vacuum cleaning machine for cleaning carpets and furniture without removal.

**Tramways and Light Railways Association.**—We have received a copy of this association's *Official Circular* for April, which contains a paper by Mr. W. F. Parish on "Friction as affected by Lubrication." There is a synopsis of the information received from various tramway undertakings, private and municipal, as to their practice regarding the limitation of liability in cases of accidents to third parties. From the latest correspondence between the association and the Board of Trade it appears that the latter intend to adhere to the existing practice as to fixing tramway speeds.

**The Telephone Transfer.**—The future of the company's staff has been the subject of communications between the Post Office and the National Telephone Company. The Postmaster-General has practically promised to include the whole of the existing staff when the undertaking of the company is taken over by the Government, but no definite arrangement in regard to pensions has yet been arrived at. An association of employés, numbering 13,000, has been formed, and promises have been given by members of Parliament to support the movement for placing their pensions on an equitable basis.

**Electrical Radiography.**—From an abstract appearing in the *Journal* of the Chemical Society of an article by Mr. V. Gabritschewski it appears that if a radium preparation and any flat object are brought for a few minutes into the immediate neighbourhood of an electrified ebonite plate, and the latter is dusted with a finely-divided mixture of sulphur and red lead, a sharply-outlined dust figure of the object is formed on the ebonite plate. It is not necessary that the object should be in contact with the ebonite plate, nor with the radium preparation. If the latter is placed on the opposite side of the plate, the figures make their appearance. The author attributes this to the existence of a special force which attracts the electrical charge of the plate towards the object in its vicinity.

**Germany's Minerals.**—A preliminary statement has been issued by the German Imperial Statistical Bureau, showing the mineral and metallurgical production of the Empire for the year 1904. The output of coal in that year was as follows: coal, 120,815,503 metric tons, of the value of £51,700,000; lignite, 48,632,769 metric tons, of the value of £5,599,900—totals, 169,448,272 metric tons and £57 299,900. Compared with 1903, there was an increase of 3·5 per cent. in the output of coal and of 6·1 per cent. in that of lignite. The quantities of other minerals and salts produced in 1904 were: iron ore, 22,047,297 metric tons; zinc ore, 715,732 metric tons; lead ore, 164,440 metric tons; copper ore, 798,214 metric tons; silver and gold ore, 10,405 metric tons; cobalt, nickel, and bismuth ores, 14,016 metric tons; manganese ore, 52,886 metric tons; pyrites, 174,782 metric tons; asphalt, 91,736 metric tons; petroleum, 89,606 metric tons.

**Electricity in British Columbia.**—It is reported that the British Columbia Electric Railway Company's great hydro-electric enterprise at Coquitlam is now completed by the successful boring of its 2½-mile tunnel. The work was commenced in July, 1902, and it was estimated that it would take three years to complete, but the engineers have accomplished their task in three months less than the allotted time. The tunnel, which runs out of Lake Coquitlam into a smaller lake called Lake Beautiful, passes under a spur of the Cascade Range of the Rocky Mountains, 3,400ft. in height, has a fall of 32ft., is 12,775ft. in length, with dimensions 9ft. by 9ft. From Lake Beautiful to the power-house on Burrard Inlet the fall is 410ft. Thence the electric energy is conveyed to the railway company's sub-stations. The overhead wires are carried from twin steel towers where they pass over navigable waters in the route. The plant is capable of developing 35,000 h.p.

**Rontgen Rays.**—A congress was opened at Berlin at the commencement of the week to commemorate the decennium of Prof. Röntgen's great discovery. A great number of scientists, statesmen, and medical men assembled to do honour to the distinguished physicist, the medical element especially gathering in force in recognition of the valuable adjunct to therapeutics provided by the professor's researches. The opportunity was taken to survey the great achievements rendered possible during the past 10 years by the discovery of Prof. Röntgen, who, it may be mentioned, has persistently refused any personal reward, feeling satisfied by the service he has rendered to suffering humanity. In the German capital, however, a public monument has been erected in his honour while still alive—a rare distinction. Numerous papers were read, these being of interest to the medical rather than the electrical profession, but all testified to the beneficence of the discovery of a scientist who has deserved well of his fellowmen.

**Electro-Therapeutics.**—In the *Lancet* for April 29 Drs. Bain, Edgecombe, and Franklin detail some extensive investigations conducted by them with a view to ascertaining the effect of certain baths and other applications of electricity on the blood, blood-pressure, and metabolism. The tests were not conducted in this instance for curative purposes, but purely in the interest of research, the authors being themselves the subjects. The authors first describe their experiments with a high-frequency current, which was administered by auto-condensation at 350 to 450 milliamperes for 30 minutes on four successive days, followed by the effleuve of the maximum intensity obtainable without sparking, applied to the whole surface of the body in succession for 30 minutes on two consecutive days. An elaborate description of the various effects follows, and we gather that the authors favour this treatment more particularly for local affections of the nerves and skin. Then follow accounts of experiments with various electric baths, including the Dowsing, Greville, immersion, and the light and ozone types, and the article concludes with a

Digitized by Google

summary of results showing the advantages of these various electrical treatments.

**Glasgow Section.**—Mr. E. G. Tidd, the hon. secretary, forwards us the fifth annual report, to be submitted at the general meeting on Tuesday next. At the same time the officers for 1905-6 will be balloted for, additional nominations having been received. The committee expresses its gratification at the satisfactory position and the progress made in the course of the past session, during which the interest manifested in the papers and discussions has been greater and more sustained than in any previous session, the attendance of members exceeding a hundred on two or three occasions. The table of membership for the last five years shows a progressive increase, the total of all grades now reaching 211, but, as is pointed out, there are many more qualified engineers in the district, and the committee express a hope that some at least of these will come into line. Special regret is expressed at the resignation of Mr. W. A. Chamen, who has quitted the post of electrical engineer to the Glasgow Corporation to enter into private practice. The social side has also been a distinct success, the inaugural dinner quite eclipsing previous functions of the kind. If the papers submitted during the session have been rather below the average in number, they have fully compensated for this in point of quality, the parent Institution having already accepted for publication Dr. Henderson's paper on "Armature Reaction in Alternators," Mr. H. B. Maxwell's paper on "Street-Lighting by Electric Arc Lamps," and Mr. W. W. Lackie's paper on "Earthing." The section is to be congratulated upon a capital season's work. Some interesting papers have already been offered for next session, and the committee hope that all members will co-operate both by such contributions and participation in the discussions.

**Niagara.**—His Excellency the Governor-General visited Niagara Falls last week to inspect the work of the Electrical Development Company of Ontario, of which Colonel Pellatt, of Toronto, who commanded the Canadian Coronation contingent, is president. This energy will be transmitted to Toronto, Hamilton, and the principal towns and cities of Ontario within a radius of 100 miles of Niagara. Lord Grey expressed himself highly upon the company's undertaking, and at the luncheon to which he was entertained His Excellency congratulated Colonel Pellatt and his fellow-directors on the progress made in their great enterprise. Reports in the daily Press state that horse-power to the extent of 25,000 will be developed by this plant, but a communication to the *Times* from Mr. J. G. Colmer explains that the company has the right to take water from the Niagara River for the purpose of generating electricity to the extent of 125,000 h.p., that the works are being constructed on that basis, that the machinery to be provided in the first instance will be sufficient for the generation of 65,000 h.p.; and that the further 60,000 h.p. can be readily made available at a comparatively small expense when it is required. The company has now obtained a concession from the Government of Ontario, subject to ratification by the Parliament of the Province, enabling it to develop an additional 125,000 h.p. The question of cheap power is attracting much attention all over Canada, and the utilisation of the numerous water powers to be found in every province for the generation of electrical power at a moderate price is confidently expected to give an enormous impetus to the development of the manufacturing and other industries of the Dominion and of local transportation facilities within the next few years.

**Radium.**—Various panaceæ for the dreaded cancer germ have been advanced from time to time, only to prove a qualified success at best, but the *Daily Telegraph* reports from America a new method which apparently contains more efficacy, solvent radium being the destroying agent. The treatment, as demonstrated at the Flower Hospital in New York, comprises the insertion of celluloid pencils coated with a solution of radium, differing from the use of radium in tubes as a destroyer of cancerous cells. Statements of the good results secured were treated with considerable suspicion until Dr. King lent the authority of his name to the value of the new treatment. That greater radioactivity is shown by radium in solution used as coating on pencils than in tubes has been clearly demonstrated. It is stated that the radium pencils inserted in the cancerous growth have destroyed the cancerous cells without breaking down the living tissues. The pencils are left in contact for 24 hours, or longer, and most satisfactory results are reported to have been obtained. Dr. William Harper, president of the University of Chicago, is cited as a notable example of the efficiency of the radium cure. A few weeks ago the doctors gave up hope in his case, declaring that he was suffering from fatal internal cancer. Since he has been under treatment by radium and X-rays he has progressed remarkably. The size of the cancerous tumour is rapidly diminishing, and has already been reduced from 18 to 7 square inches. Two cases guaranteed by Dr. King as genuine radium cures are those of a man treated for cancer of the tongue and of another for cancer of the foot. In both instances the growth has disappeared. Important experiments with the new agency are now being conducted at the leading hospitals in New York.

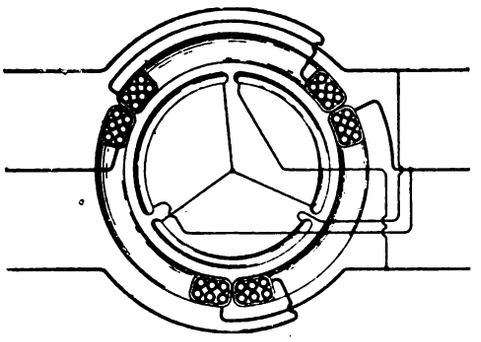
**Electric Lighting in the States.**—The Legislative Committee is proceeding with its investigation into the electric light and gas services of the city of New York. Evidence was given by Mr. Arthur Williams, of the New York Edison Company, that if the average hours in use were taken into consideration, current in bulk would cost the city 30 per cent. more than it does now, the average number of hours of service in the city buildings being very low. In reply to a question as to whether the company had a single customer who used approximately the same amount of current as that furnished to the city buildings, Mr. Williams replied that they had, and that the rate of supply was 1½d. per kilowatt-hour. Evidence was then given as to the financial relations of the Empire City Subway Company and the New York Telephone Company with the New York Edison Company, from which it appears that the latter are paid £40 per mile annually for maintenance of ducts by the Empire Company. The assets of the New York Edison Company were stated to total 5½ million pounds, exclusive of goodwill. The finances of the companies are being investigated in some detail, owing to suggestions of large profits through exorbitant charges. The situation in Brooklyn, the large New York suburb, was then dealt with. The treasurer of the United Electric Light and Power Company stated that the amount written off for depreciation averaged ½d. per unit, the same as the amount allowed by the New York Edison Company. This brought the average cost per kilowatt-hour sold up to 2·86d. Colonel Robert Grier Munroe, ex-commissioner of water supply, gas, and electricity, who had made allegations against the companies of excessive charges, admitted that his assertion was not based upon investigations, and that a comparative list of rates in different cities which he had published contained several discrepancies.

**Polyphase Meters.**—The American Institute of Electrical Engineers received on the 28th ult. a paper by Mr. J. D. Nies, entitled "Some Notes on Polyphase Metering." In these the author deals with the various ways in which the energy supplied to consumers by the three-phase

Digitized by Google

system may be measured. He deals particularly with large consumers, whose demand may range from 200 kw. up to 1,000 kw. It seems that in America polyphase meters have been largely used for such consumers, and that it is the practice to put two of these meters in series. As is to be expected, the results obtained in such cases are by no means concordant. The reason of this is that with a polyphase meter so many elements enter into the final reading that a large variety of errors can easily be introduced. The author goes into these, and shows the influence of current transformers on the accuracy of the reading throughout the full range of the meter and with differences in the power factor of the demand. At light loads and with low power factors the error caused by the use of current transformers may be serious. He also deals with the influence of the drop in the common return if a two-meter method is used. His conclusion after going into the various errors which can be introduced is that the most accurate method is to use three single-phase meters and to take independent records from each. It is true that there are errors which would affect all these three meters in the same way, but the chances are that they will not develop the same defect simultaneously. Under normal conditions, therefore, one should get equal readings from each meter, and if this is not the case it shows that there is something about either the meters or the installation which requires attention. Each meter should be connected between one wire and the neutral of the system. In those cases where the neutral conductor is not available it can be easily obtained by using pressure transformers, since the secondaries of these can be connected up in star fashion.

**Phase Indicator.**—A novel form of phase indicator has recently been patented in the United States by Mr. P. G. Watmough, jun., of Schenectady, and assigned by him to the General Electric Company. The device, which is described in the *Electrical Review* of New York, is of particular value for use in connection with



multiphase circuits for showing the phase difference between current and E.M.F. The instrument comprises two relatively rotatable members, the windings of one being connected in series with the polyphase mains, while the windings of the other are connected in shunt. Two connections are so made that the windings of each member when traversed by current set up a rotary magnetic field, the direction of rotation of the fields being the same. The movable member of the indicator assumes a position such that the polar line of the magnetic field due thereto is brought into coincidence with the polar line of the magnetic field due to the stationary member of the instrument. Since the two magnetic fields revolve at the same speed, the two members of the instrument remain in fixed relation to each other so long as there is no change in the phase relation between the currents in the two members. As soon, however, as the current in the polyphase mains begins to lag or lead, the field due thereto shifts backward or forward to correspond, thereby causing the movable member of the indicator within the influence of this field to shift correspondingly. The angle of displacement of this movable member thus furnishes a measure of the phase displacement between the current and the E.M.F. of the polyphase circuit.

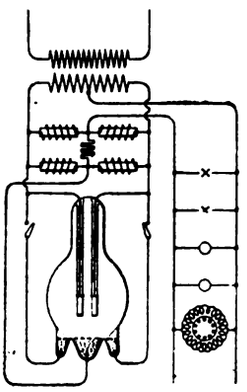
**Royal Institution.**—The annual meeting of the members of this institution was held on Monday afternoon, the Duke of Northumberland, K.G., president, in the chair. The annual report of the Committee of Visitors for the year 1904, testifying to the continued prosperity and efficient management of the institution, was read and adopted, and the report on the Davy-Faraday Research Laboratory of the Royal Institution, which accompanied it, was also read. Seventy-one new members were elected in 1904. Sixty-three lectures and 19 evening discourses were delivered in 1904. The books and pamphlets presented in 1904 amounted to about 267 volumes, making with 721 volumes (including periodicals bound) purchased by the managers a total of 988 volumes added to the library in the year. Thanks were voted to the president, treasurer, and the hon. secretary, to the Committees of Managers and Visitors, and to the professors, for their valuable services to the institution during the past year. The following gentlemen were unanimously elected as officers for the ensuing year: president—The Duke of Northumberland; treasurer—Sir James Crichton-Browne; secretary—Sir William Crookes; managers—Sir William de W. Abney, the Right Hon. Lord Alverstone, Henry E. Armstrong, Esq, Shelford Bidwell, Esq, Sir Alexander Binnie, the Hon. Sir Henry Burton Buckley, the Right Hon. Charles Scott Dickson, Francis Elgar, Esq., Maures Horner, Esq, Dr. Ludwig Mond, Sir Andrew Noble, Bart, the Right Hon. the Earl of Rosse, Sir Thomas Henry Sanderson, Alexander Siemens, Esq., and Silvanus P. Thompson, Esq.; visitors—Dr. William Arthur Brailey, Dr. John Mitchell Bruce, Sir John George Cragge, Dr. James Mackenzie Davidson, Francis Fox, Esq, Robert Kaye Gray, Esq., Lord Greenock, Charles Edward Groves, Esq., A. Kirkman Lloyd, Esq., M.P., Sir Philip Magnus, Carl E. Melchers, Esq, Emile R. Merton, Esq, George Johnstone Stoney, Esq., John Jewell Vezey, Esq., and George Philip Willoughby, Esq.

**Electrolytic Estimation of Arsenic.**—The *Journal* of the Chemical Society contains an abstract of an article by Messrs. Carl Mai and H. Hurt, in which the authors describe their investigations regarding the electrolytic estimation of small quantities of arsenic and the apparatus employed. This latter consisted of a wide U-tube, in which the decomposition is carried out, and a six-bulb absorbing tube. Between these two parts, and connecting them, is placed a tube filled with pumice-stone soaked in alkaline lead solution. The electrodes consist of pure sheet lead. The ends of the U-tubes are closed with caoutchouc stoppers, through which pass glass tubes, elongations on the lead plates being cemented in these tubes, so that a plate is suspended in each limb of the U-tube. A safety tube passes through the cork of the anode limb, whilst the cork of the cathode limb is pierced by the capillary stem of a tapped funnel and the delivery tube of the apparatus. The U-tube is about two-thirds filled with a 12 per cent. sulphuric acid solution, and 10 c.c. of N/100 silver nitrate solution are placed in the bulbs of the absorption tube. The current may be obtained direct from the main and should be controlled by a suitable resistance. The solution to be examined is introduced drop by drop from the tapped funnel. Should arsenic be present, the silver solution is darkened, and at the end of two, or at the most three hours, the reduction is completed. The reduced

Digitized by Google

silver is collected on an asbestos filter, washed with a little water, and the excess of silver in the filtrate titrated with N/100 thiocyanate solution. One c.c. of N/100 silver nitrate solution is equivalent to 0·124 mg. of metallic arsenic. For quantities of less than 0 02 mg., the titration method fails and a calorimetric one must be employed, when 0·001 mg. of arsenic may be estimated and 0·0005 mg. detected. For the detection of minute traces, the absorption tube may be replaced by the combustion tube of a Marsh apparatus and a mirror obtained in the usual way. The authors state that all organic matter must be destroyed before estimating arsenic in such articles as beer, urine, etc. The results appear to be similar to those described some months ago by Mr. W. Thompson, to which we referred in our issue of July 1 last.

**Frequency Changer.**—An interesting application of the mercury-vapour rectifier embodied in a patent recently granted in the United States to Mr. O. O. Kruh is described in the *Electrical World* of New York. Although the inherent characteristics of the rectifier are such as to deliver a pulsating unidirectional current, the inventor proposes to use the rectifier in combination with inductance coils to obtain an alternating current of double the initial frequency. The connecting circuits are shown in the accompanying diagram. The two carbon anodes are



connected to the secondary leads of the main supply transformer. Owing to the selective behaviour of the mercury cathode, the current flows alternately through the anodes in a constant direction to the cathode. The inductance coils store energy during the time when current is flowing from one anode to the cathode, and discharges this energy in such a manner as to cause the current to continue to excite the cathode until the wave of E.M.F. has so far reversed as to start the flow of current from the other anode. The effect of the inductance coil in the circuit of the cathode is normally to fill up the gaps in the unidirectional current waves, and thus to produce a more or less even direct current. Instead, however, of merely filling the gaps in the current waves in the consumption circuit, the inductance coils as here arranged deepen the depressions, so to speak, and cause them to extend across the neutral line of current, and so produce an alternating current. The object of the use of four inductance coils and the connecting resistance is to equalise the waves due to the direct flow of current from the source and the waves of opposite polarity produced by the discharge of the inductance coils. The inventor claims that when the apparatus is arranged as here indicated all dissymmetry of the current is eliminated, and a smooth double-frequency current is obtained.

**The Italian Railways.**—Between the question of State control or the leasing of the lines and difficulties with the employés the Italian Government has had little opportunity for taking into serious consideration the suggestions for electrifying the railways of the peninsula which have been made from time to time. The country's bountiful water supply has been a considerable factor in the great expansion industrially which electricity has undergone in Italy during the past decade, and this has encouraged the idea that the same source of power might be utilised to drive the railways. Apart from technical questions, however, the commercial phase enters largely into the matter. In 1885 the railways were leased to companies for a term of 60 years, determinable by either party at the end of 40 or 20 years. It has long been known that the arrangement has not been satisfactory to either party, and at the end of next month the administration of the system will revert to the State, as negotiations with the companies for amended contracts proved abortive. The companies have been greatly handicapped by the demands of the railway employés, and the State seems likely to find the concessions to the staff provided for in the Bill which has just passed through the Italian Parliament a serious incubus for some years. In a memorial to the Throne last October it was claimed that "the State would be in a better position than a private undertaking to find a solution for the vexed question of the status of railway employés, and by guaranteeing their rights and exercising a just but rigid disciplinary control, to remove once for all any further occasion for strikes." The means taken by the Government to allay discontent consist of the establishment of a widows' pension fund, an advance in pay, and from the beginning of next year a share in any profits. If the receipts show a material improvement, it will probably be easier for the Government to provide a solution of the labour difficulty than for the companies, as stated in the above-mentioned memorial, because the Government will not now have to share any profits with lessees. On the other hand, if the financial position does not improve, the concessions to the employés are likely to entail further taxation upon Italy's overburdened citizens. It will be some recompense, however, if the new *régime* succeeds in averting such dislocations of the system as the labour troubles of a few weeks ago entailed Provision is made in the Bill for the improvement of the railways during the next 10 years, but the reforms are apparently in the nebulous stage at present. The measure is of a tentative character, and the future of the railways is left in a rather hazy condition; but by the time economic considerations permit of a general electrification scheme being entertained, the relative advantages of three-phase, single-phase, and direct currents for such work should be definitely determined.

**Testing Alternating-Current Generators.**—Messrs. H. M. Hobart and F. Punga contribute to the *Electrical World* of New York an article in which they describe a new method of testing large alternating-current generators. As one of the primary guarantees given by dynamo manufacturers is that the temperature elevation of the machine under continuous load shall not exceed a stated amount, the importance of such tests is obvious. Little difficulty in this respect occurs with small dynamos, but when the capacity reaches 1,000 kw., it usually becomes quite impracticable to supply the required load for the test in the factory, especially as the time during which the machine mounts up to its final temperature elevation is much larger. This renders it necessary to devise some convenient arbitrary method of testing for temperature elevation that shall not involve the waste of large amounts of energy. The authors commence by briefly reviewing the difficulties attending heat tests of large alternating-current generators, and allude to the drawbacks of the pro-

Digitized by Google

posals of Mordey and Behrend, which involve special connections of the armature windings or of the field windings, in order to reduce the amount of power required for the test to the reasonable value represented by the internal losses of the machine. Such systems, moreover, have the great disadvantages that the method of reversed field windings is applicable only when the number of poles is very great, and it is not permissible to subdivide the field winding into two groups only, such connections being attended by a considerable degree of mechanical vibration. The authors' method requires no alterations to the windings, and no greater expenditure of energy than is necessary for covering the internal losses, and it has the advantage that the heating at all parts of the generator will be identically the same in distribution and amount as under actual full-load conditions. It is necessary that the component losses in the machine shall be determined in advance, as would in any event be done in the ordinary course of the tests. Instead of maintaining a steady testing *régime*, they test the machine on short-circuit and on open circuit alternately. During the short-circuit periods they send excessive current and energy into the armature copper with very weak field excitation, while during the open-circuit periods they send excessive energy into the field-magnet circuits with over-excitation. The cycle of operation is made 15 minutes, and the average power thus expended in the machine is made equal to that steadily wasted during the full-load operation. Although the thermal conditions of double or treble current strength with intermissions are not the same as those of steady normal current strength, the difference between them is likely to be insignificant in the case of very large machines, and in any case it is probably less than in other forms of test. The method promises much utility, and in any case it would be highly interesting, as our American contemporary remarks, to have it thoroughly tested.

**The Institution.**—Last week's meeting of the Institution was occupied with the discussion of Mr. F. Creedy's paper on "The Alternating-Current Series Motor," taken in conjunction with the presidential address delivered at St. Louis by Mr. B. J. Arnold. The ball was set rolling by a visitor in the person of Mr. T. H. Schoepf, who stated that Mr. Creedy's experiments had vindicated the theory of the alternating-current series motor. More difficulty was likely to be experienced in designing such motors for high than for low frequency. There were difficulties in the way of designing 100-h.p. or 150-h.p. motors of this type for traction, and he considered that the maximum frequency practicable in motors of large capacity for such purposes would be limited to 25 cycles. Sparking and unsatisfactory commutation were factors which confronted the railway engineer in this connection. The design of the winding was an important feature in the single-phase motor. He then defined the essentials of a good motor, which needed to be efficient and to possess the highest power factor possible. These two factors were influenced by the shape of the speed curve, which must yield good general results. Describing tests he had conducted upon an equipment comprising two 150-h.p. motors, he stated that the most important point related to the power factor. At the moment of starting this was about 26 per cent., and a maximum of 96 per cent. was attained. The rate of acceleration was one mile per hour per second. He anticipated favourable results from a 225-h.p. motor designed for a frequency of 18 cycles. Mr. Alexander Russell, who took exception to the author's method of calculating the efficiency of the series motor, considered that the paper clearly demonstrated the inferiority of the simple alternating-current series motor to the direct-current series motor. The next speaker was a youthful visitor from the States, Mr. L. Calisch, who has had personal experience of the series motor as operated upon the new line from Schenectady to Ballston. The motor used there can run with either direct or alternating current, and possesses a high power factor. He described a motor in use on the line which had an efficiency of from 70 to 79 per cent. with alternating current, and between 70 and 85 with direct current. With alternating current the power factor was 95 per cent. In conclusion, he expressed the conviction that the alternating-current motor had come to stay. The views of the speaker, who, like the author, is an ex-pupil of Prof. Ayrton, were enunciated with conspicuous precision, and the professor's countenance assumed an expression of gratification at the enthusiastic applause accorded his erstwhile *protégé*. Prof. Carus-Wilson remarked that in consequence of trade rivalry it had been rather difficult to obtain information on the subject of the alternating-current series motor. The power factor of motors of this type might be anything that was required, the question being whether a high power factor permitted of a form of design which provided a good railway motor. An improved power factor could be obtained by decreasing the number of armature turns—a conspicuous feature in the tendency of modern design in railway motors—if the limitations of rating were borne in mind, and this yielded what was considered a good design for railway operation. It appeared to him that the alternating-current series motor had not as high an overload capacity at starting as the direct-current type. Apparently the sphere of usefulness of alternating-current motors would be for high-speed running over long distances where few stops occurred. Prof. Ayrton stated that he thought Mr. Russell's criticism was based upon a misconception. He emphasised the point brought out by the author that the armature of the motor, not the field magnet, was relatively the more important consideration. Mr. Mordey alluded to the warning given at St. Louis by Mr. Arnold against the idea that electricity would ultimately lead to the extinction of the steam locomotive. He believed electrical engineers were agreed that the latter must at any rate remain on lines where the service was infrequent and the cost of electrification heavy; but he rallied Colonel Crompton upon a remark which he understood the colonel had made in his "James Forrest" lecture, to the effect that the steam locomotive could do all that electric traction could. He imagined that as Colonel Crompton was addressing the Civil Engineers on that occasion he desired to himself be a very civil engineer. Particularly in regard to acceleration and climbing heavy gradients Mr. Mordey did not think the former could compete with its rival, nor was it likely to attain the remarkable speeds achieved during the Marienfelde-Zossen trials. It appeared, however, that these remarks of Mr. Mordey's were based upon misapprehension—as, indeed, the speaker thought might be the case—Colonel Crompton's remarks applying to comparatively level tracks. It appeared to Mr. Mordey that the alternating-current motor could do all that the direct-current type could; and if some loss of efficiency occurred, there were ample compensating gains. Mr. Creedy replied in summary form, claiming that the alternating-current series motor permitted of an increased voltage for a short period, thus solving the overload problem. The President gave the audience some reminiscences bearing upon the subject, from which he drew the moral that young engineers should not despair if they did not immediately achieve a commercial success when carrying out experimental work, and then the proceedings concluded with a hearty vote of thanks to the author.

## THE VALTELLINA RAILWAY.

### Working Costs and Test Figures obtained with Three-Phase Traction.

BY E. CSERHATI.

The main railway in the North of Italy, generally known as the Valtellina line, was opened for regular service on July 10, 1904, and is now operated by the Rete Adriatica. This railway company has taken over the whole plant erected by Ganz and Co., of Budapest, three months prior to the expiration of their period of guarantee. As this line had previously been worked regularly and opened for public traffic for 21 months, the experience obtained allows of the different items of working cost being ascertained with fair accuracy. On the other hand, thorough tests have been made by the engineers of the railway company in regard to the working efficiency and other important features of three-phase railway working. In the following article there will be given a brief summary of the results obtained by irregular working and on special tests.

The working cost for staff and material in the Morbegno power plant for the period from July 1, 1903, to June 30, 1904, amounted to 21,553 lire. During this period 3,420,502 kilowatt-hours were generated. Thus the works cost for generating a unit amounted to 0 63 centesimi, or about 0·66d. The cost for labour and material incurred for maintaining and inspecting the overhead conductors, poles and transformer stations included, amounted to 329 lire per kilometre of permanent line—*i e*, about 17s. 4d. per mile per annum. Expenses for maintenance and repairs of rolling stock, including electrical equipment and mechanical parts, per locomotive or motorcar kilometre amounted to 4·36 centesimi—*i e*, about 0·66d. per locomotive or car mile. The total expenses for service, including oil, stores, and management expenses, amounted for the period with but partly electrically-driven goods trains to 1·97 lire, for the period with trains conveyed exclusively electrically to 1·71 lire per 1,000 ton-kilometres—*i e*, 2s. 6d and 2s. 2d. per 1,000 ton-miles respectively.

The corresponding expenses on a steam line in Austria, selected by way of comparison owing to its representing conditions similar to the Valtellina as regards curves and gradients, although with a 30 per cent. denser traffic, amounted to 4 20 lire per 1,000 ton-kilometres. From the capital cost figures it has been calculated that the saving effected in traction expenses on the Valtellina line correspond in the first case to 3·98 per cent. on the capital expenditure, and in the second case to 5·53 per cent. The free lighting of all stations and motorcars, as well as heating of the latter, is also given by the electrical equipment.

*Current Consumption Tests.*—During the two years' operation of the Valtellina line thorough tests have been made as to current consumption and recuperation on levels and on gradients, as well as the energy consumed at starting the trains. These tests were undertaken by the engineers of the Rete Adriatica, Messrs. Novi and Donati, under the co-operation and superintendence of Mr. Celeri, engineer to the Italian General Inspection Service. The results of the same were published for the first time at the Congress of Italian Electricians held at Bologna in 1904. The test figures given herewith are taken from the reports of this congress. As mentioned above, 3,402,502 units were generated at the Morbegno power plant during the year. The number of ton-kilometres, including weight of locomotives and the electrical equipment of motorcars for the same period, amounted to 76,845. Therefore, the energy consumption per ton-kilometre averaged 44·3 watt-hours measured at the distributing board of the power station—*i e.*, 71·4 watt-hours per ton-mile. In these figures are included: (1) the energy required to drive the trains; (2) all the losses between the distributing switchboard of the power station and the driving wheel of the rolling stock; (3) the current for lighting all stations, for which 1,254 incandescent lamps of 16 c.p. are used; (4) the current for lighting and heating the motorcars and locomotives; (5) the consumption in the accumulator charging stations equipped with two motor-dynamos each of 21 kw. capacity on the continuous-current side; (6) the consumption for driving the machinery in the workshop at Lecco; (7) the energy required for the shunting service; (8) energy consumed during various tests made for the purpose of inspecting the electrical apparatus and equipment. The above-mentioned figures showing the average energy consumption of 44 3 watt-hours per ton-kilometre were ascertained by the above-named engineers of the Rete Adriatica.

The net consumption per ton-kilometre was ascertained by means of a motorcar specially equipped for the purpose, being fitted out with ammeter and recording wattmeter for both overhead phases. The average of 20 tests showed a consumption of 31 watt-hours per ton-kilometre—*i e*, 50 watt-hours per ton-mile measured in the car. This figure quite agrees with the test results obtained by the staff of Messrs. Ganz and Co. These tests were extended with a view to establishing the net consumption in the power station, the train used for the purpose having run during the night after the termination of the regular service. The current consumption per ton-kilometre amounted to 34 9 watt-hours, and, therefore, the working efficiency of the system to 88 8 per cent. In order to duly appreciate the importance of the figures quoted, it must be borne in mind that the profile of the Valtellina is a very unfavourable one, the average gradient of the whole line, as taken for both directions, amounting to ·25 per cent.—*i.e.*, a train running through all sections in both directions, from one end to the other, and returning to the starting point, must be lifted about 527·5m., which height corresponds to the mentioned average gradient, the length of the run being $2 \times 106{\cdot}5 = 213$ km. The section between Lecco and Colico on which the energy consumption tests were carried out had an average gradient of 0 21 per cent., hence the 31 watt-hours must be regarded as the specific consumption per ton-kilometre at a speed of 60 km., or 37·2 miles per hour on a constant gradient of 0·21 per cent, including starting. For acceleration from rest to a speed of 60 km., 95 watt-hours are required per ton weight; losses arising in the motor and rheostat amount to six watt-hours per ton-kilometre. Assuming an efficiency of 85 per cent. for the motors, the motor losses amount to 4 6 watt hours, so that there remain but 1·4 watt-hours for rheostat losses—*i e*, 4½ per cent. of the total specific consumption.

A 120-ton train consumes 31 watt-hours per ton-kilometre at a speed of 60 km. per hour while continually running on level track. A motorcar running singly requires 48 watt-hours per ton-kilometre, including starting energy. The large difference as compared with the 31 watt-hours for a 120-ton train is due to air resistance, which is diminished for a given weight by the increase in length of a train. It will be seen that from economical considerations it does not appear to be advisable to replace heavy trains by numerous light trains or cars. Moreover, it shows that rheostat losses at starting are on this line very small compared to the whole energy consumption.

*Recuperation of Energy.*—It is well known that alternating-current induction motors have the power of restoring energy to the line when running on down grades over a certain decline, which varies according to traction resistance, while the speed is thus maintained practically constant. The commercial value of this property has very often been doubted. However, the respective tests not only proved the possibility of recuperation, but settled at the same time the quantity of energy which could be returned to the line. On a section with a down grade of 2 per cent., with a 120-ton train and a speed of about 30 km. per hour, 28 2 watt-hours—*i.e*, about 80 per cent. of the energy—has been recuperated which otherwise would have been lost by the braking. The exceedingly favourable result in regard to energy consumption of the Valtellina line is due chiefly to this circumstance. The question as to how to utilise the energy recuperated has likewise been often discussed. The simplest solution would evidently be to equip for electric traction not only the steep grades of mountain lines, but also the adjoining level sections, in order to assure the utilisation of the return current from descending trains. The energy recuperation may be taken advantage of not only when trains run on down grades, but also when stopping the same, provided that the motors are designed for cascade working; in

Digitized by Google

this case the speed will be reduced to within a fraction of synchronous speed when switching over to the cascade connection, and the energy which has been required for train acceleration from rest to full speed is partly given back by the momentum of the train. The current recuperated in this way amounts to from 35 to 40 per cent. of the energy for acceleration, and to about 10 per cent. of the total consumption. This advantage becomes of utmost importance in suburban railway service, where heavy trains have

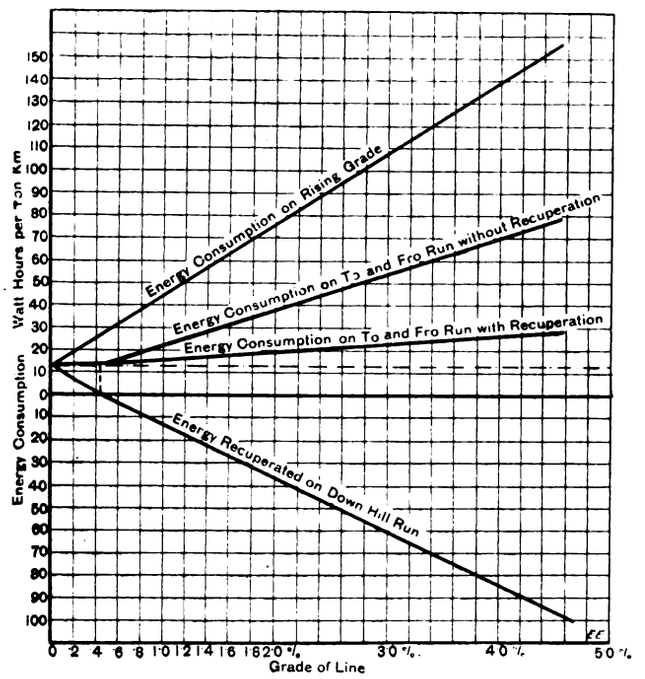

FIG. 1.—Curves for speed of 31 km. or 19·3 miles per hour. Drawbar pull, 8,000 kg. Traction resistance, 4 kg. per ton.

to be started and stopped in relatively short distances. It has, for instance, been proved—in a scheme worked out for the Vienna suburban lines—that with a four-step cascade connection, by means of one or two parallel working primary and two secondary motors connected in different combinations, more energy would be given back at stopping than the rheostat losses amounted to at starting. The importance of these facts cannot be denied either in the case of main railways when looking at the matter from an economical point of view, inasmuch as mixed and local

very simply as a function of the gradient. Assuming that the motors work with an efficiency of 100 per cent., the energy consumption per ton-kilometre expressed in watt-hours will be

$$s = c\,(w \pm l),$$

$c$ being a constant, $w$ the resistance on the level, and $l$ the gradient represented in metres per kilometre. The upper sign is to be applied on up grades, the lower one on down grades. The equation represents two straight lines cutting the ordinate axis at the same point. Halving the sum of

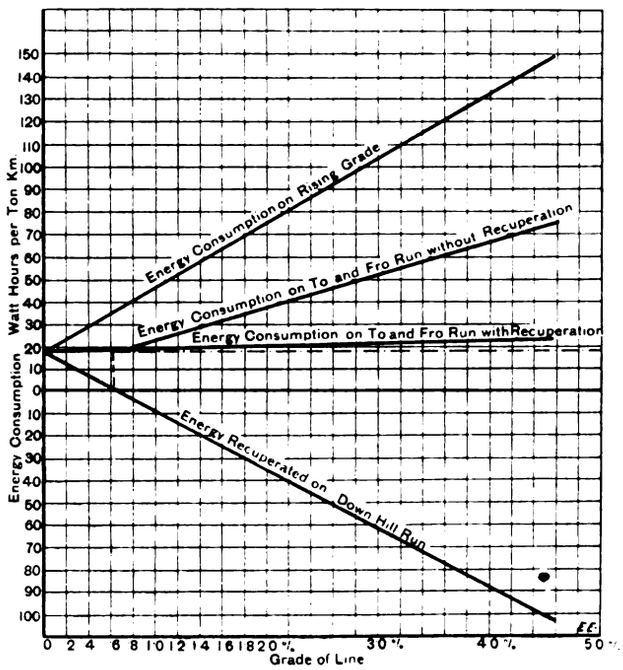

FIG. 2.—Curves for speed of 62 km. or 33·6 miles per hour. Drawbar pull, 5,000 kg. Traction resistance, 6 kg. per ton.

the ordinates, we get the average current consumption for a complete run to and from over a given section with due regard to recuperation. The equation shows that, provided motors would work with an efficiency of 100 per cent., the average current consumption would be the same on lines with grades as on level ones. By means of these equations and the curves showing motor efficiency at different loads the curves Figs. 1 and 2 have been drawn. They show the current consumption and recuperation on down grades from 0 to 4·5 per cent., and for speeds ranging from

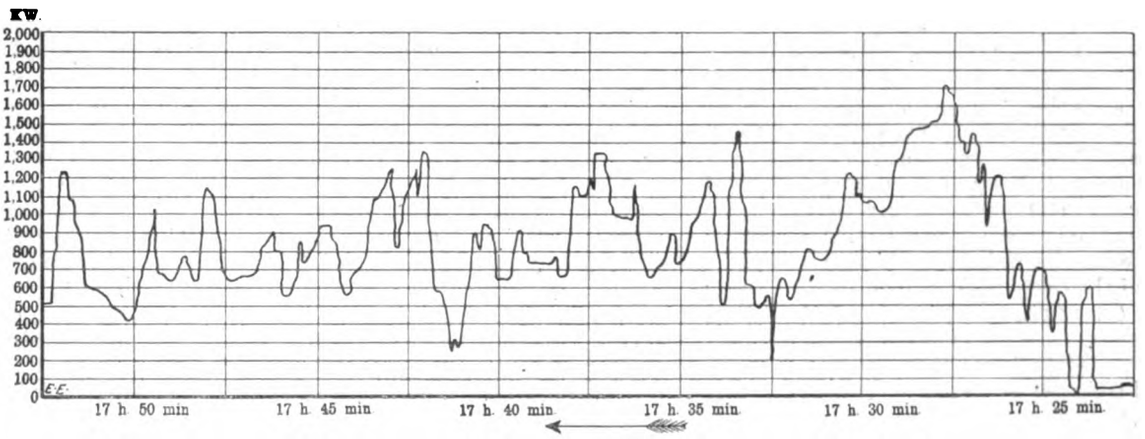

FIG. 3.—Record taken from the Registering Wattmeter at the Morbegno Power Station.

trains must be stopped rather frequently from high running speeds. The acceleration of these trains represents an important part of the total energy required. With simple cascade working, 35 to 40 per cent. of this energy, as above mentioned, may be saved, with four-step connections even more. In the case of water-power stations the energy recuperation is so far of importance, as it allows of a line with denser traffic or greater length being worked from the same plant than would be the case without recuperation. With steam plants much saving is effected in working cost.

*Energy Consumption as a Function of Gradients.*—For a certain speed the energy consumption may be represented

30 km. to 60 km. per hour. The half of the algebraic sum of ordinates represents also in these cases the actual consumption of a complete run up and down the hill. As will be seen, the consumption increases with the gradient relatively slowly. Where the curve cuts the abscissæ, when running down the hill, we get the down grade on which the train takes no energy from the line. In Figs. 1 and 2 a curve has likewise been drawn which gives the average energy consumption for a complete run when the train descends without recuperation, as no energy is required in the latter case. We therefore get the average consumption for a cycle by halving the ordinates for the up-grade run.

Digitized by Google

From the above it will be clearly recognised how the economy increases with a system affording recuperation compared with one lacking that quality. The difference in favour of a three-phase system allowing recuperation on down grades is as follows:

| | | | | | |
|---|---|---|---|---|---|
| With gradients of ..... | 1·0 % | 2 % | 3 % | 4 % | 4·3 % |
| At a speed of 30 km. per hour | 40 % | 100 % | 132 % | 165 % | 169 % |
| ,, ,, 60 km. ,, | 90 % | 150 % | 200 % | 250 % | — |

*Flywheel Effect.*—As will be seen by the watt diagram (Fig. 3) taken at the Morbegno power station, the current rushes due to the starting of even the heaviest trains do not represent higher peaks than about 70 to 80 per cent. of the energy requirements corresponding to the average consumption of the train when running on the line. This favourable circumstance is due, in the first place, to the use of water rheostats, which give such a smooth starting that it is not easy to tell the exact starting moment. At the same time no sudden current rushes can arise due to this method of control. In the second place, it is due to the peculiarity of induction motors to take no current from the line as soon as the periodicity of the supply is reduced by about 1 to 2 per cent. If the latter is further diminished, then current is given back to the feeding conductors by the running trains. When starting a heavy train, the number of revolutions of the generators and prime movers is reduced and the periodicity diminished. Consequently, the short-circuited motors of the running trains will take no current until their speed drops below the value corresponding to the number of revolutions at the power plant. In this way the latter is relieved when starting up a heavy train. Should it happen that the number of revolutions of the generators is reduced suddenly by more than 2 per cent., current would be returned to the feeding line by the motors of all moving trains—that is to say, the whole of the moving train masses would represent a huge flywheel, having the effect of reducing very considerably the current rush from the power plant. This is an exceedingly valuable peculiarity of the three-phase traction system, which should be duly appreciated, as up to the present time very little attention has been paid to it.

On the latest type of the Valtellina locomotives* the slip-rings are not placed between the locomotive frames, but outside of them, as by this arrangement accessibility for supervision is facilitated, also the space inside the frame is then available for the motors, which can be made more powerful than would be the case with slip-rings arranged inside. This arrangement necessitates the three ends of the rotor winding being taken through the hollow crankshaft, the crank arm, and pivot, and also through the counter-crank to the three slip-rings. It is not difficult to carry out this arrangement with three conductors insulated from each other. If, however, the collector of a continuous or single-phase alternating-current motor were arranged in this way, more than 100 conductors would necessarily have to be brought out. This, although it would not be impossible in a technical sense, is at all events a very difficult matter. The possibility of thus equipping the locomotive with very powerful motors should be well appreciated, for the smaller the number of motors for a given total horse-power, the less the weight, and the simpler the mechanical features of the electric locomotive.

*Energy Consumption Compared with that of other Systems.*—The current consumption per ton kilometre is influenced by a great many circumstances, such as speed, gradient, curves, weight of train, length of train, distance between stations, etc. It is, therefore, difficult to compare the figures showing consumption of different railways equipped for different traction systems. Moreover, very little information has been published as to energy needed for the main-line railways or on lines with main railway traffic. This information applies usually to the consumption measured in the car, but not on the distribution board of the power plant. The gross consumption of 44 watt-hours per ton-kilometre, which includes all losses and the supply to other electric apparatus on the Valtellina line, must be regarded as a very low one, as most of the figures known concerning other lines and representing the consumption in the car are higher. Further, it must be considered that with direct-current lines the losses between the switchboard of the power plant and the line side of the rotating transformer sub-stations amount to about 20 per cent. On other systems a net consumption as low as 31 watt-hours (measured in the car) has never been reached before and with a profile similar to that of the Valtellina Railway. Figures relating to consumption on direct-current lines do not offer any particular interest, as nobody is likely to think nowadays of equipping any line of great length with the direct-current system, as this system is more expensive both as regards first cost and working expenses. More attention should be paid to the respective figures of single-phase railways, which, on the whole, offer the same advantages in regard to energy transmission on an extensive railway system as the three-phase traction system. In the *Street Railway Journal* of Aug. 24, 1904, are published the interesting results of tests carried out by the General Electric Company on an experimental line equipped between Schenectady and Ballston. A test run has been made there with the same motors, the latter having been fed first with direct and then with single-phase alternating current. The results show the following energy consumption: 53·5 watt-hours per ton-mile for direct current, and 78·1 watt-hours per ton-mile for single-phase alternating current. Hence 46 per cent. more current has been consumed by the same motor under identical conditions for single-phase alternating current than for direct current. Three-phase motors may be built with at least as high an efficiency as that of direct-current motors, and therefore conclusions may be drawn from the above test results as to the mutual behaviour in reference to energy consumption of three-phase and single-phase traction motors. The latter will require about 40 to 50 per cent. more energy than three-phase motors, provided that conditions be the same as those prevailing as the mentioned tests. According to Glaser's *Annalen*, 1904, No. 3, the Niederschoneweide-Spindlersfeld monophase railway of 4·1 km. length requires 45 watt-hours per ton-kilometre with a distance of 908m. between stations, a maximum speed of 34·6 km. per hour, and with a train weight of 170 tons. It must be remembered, however, that this line has no gradients, except one of 0·2 per cent. on a 500m. section.

In a scheme worked out by Ganz and Co. for the Vienna Suburban Railway, the watt consumption of a train of the same weight at a maximum speed of 31 km. per hour, and an average distance of 906m. between stations, has been stated at 30·7 watt-hours, and the firm was prepared to guarantee that figure. Also in this case the difference in energy consumption amounted to 45 per cent. in favour of the three-phase system, although on the Vienna line there are gradients up to 2·9 per cent. According to a publication in the *Zeitschrift für Elektrotechnik*, No. 3 of 1905, the Stubaithal Railway requires 70 watt-hours per ton-kilometre. The corresponding energy consumption has been figured out on the basis of an exact profile of the above line for three-phase traction with the same speed as that given in the mentioned publication, and without using cascade connection. For a complete cycle run in both directions with a train supposed to come back to the level of departure, an average consumption of 29·4 watt-hours per ton-kilometre has been arrived at in the car, thus about 31 watt-hours measured at the feeding point. This low figure is accounted for by the recuperation when trains run down the hill, and which amounts to 27·6 watt-hours, whereas the consumption on a run up grades is 57 watt-hours per ton-kilometre. The above figures relating to energy consumption on single-phase railways are taken from publications of the contracting firms. Those relating to the three-phase system have been ascertained by official tests of the Rete Adriatica, or, at least, represent conclusions drawn from the latter.

The peculiarities of the three-phase traction system as discussed in the foregoing represent the following advantages: (1) the possibility of recuperating both the energy stored up in the moving trains when the speed is being reduced at stopping, and also the energy available with the train running on down grades (this results in a low total consumption energy); (2) the reduction by flywheel effect of the current rushes arising owing to the starting of trains; (3) the possibility of arranging the slip-

* See description in the *Electrical Engineer*, vol. xxxv., pp. 155, 261, 403.

Digitized by Google

rings apart from the motors, and thus to utilise the whole space available inside of the locomotive frame for motors. These advantages are obtained only by the use of induction motors amongst the different types, of which the three-phase motor. By choosing a motor other than of the induction type all the before-enumerated advantages are forfeited. On the other hand, with three-phase motors one is restricted as to variable speeds. Steam locomotives, as is known, may run with any desired speed within certain limits, which are fixed by the capacity of the boiler and the security of service. The behaviour is similar with direct and single-phase current series motors, whereas polyphase motors will run but at a few determined speeds according to the frequency, number of poles, and diameter of driving wheel. This feature of polyphase traction has been regarded as a drawback; but since the results of the operation and the experience gained during a two years' service on the Valtellina Railway have become known the peculiarity in question is recognised as an advantage by experienced railway men. The chief condition for a regular traffic is an exact observation of the time-table. All working systems allowing the staff to vary the speed require a highly trained staff, which, as it were, grow to living tachometers. Such experienced drivers will only give a safe service on lines with which they are well acquainted, and therefore their employment is limited. The polyphase alternating-current traction system does not require such a thorough training of the personel, owing to the speed remaining automatically constant without regulation after having reached the value peculiar to the system. Indeed, even on lines with a variable profile, the speed diagrams taken from actual service are almost horizontal lines. Thus individual skill of the staff is nearly eliminated, being restricted to correct starting and stopping. The property alluded to of the three-phase traction system is likewise important from a strategical point of view; besides, it materially facilitates the drawing-up of new time-tables.

## RELAYS FOR DIRECT AND ALTERNATING CURRENT CIRCUITS.

[CONTRIBUTED.]

The most important requirement of the modern central station is continuity of supply, which must be maintained under all conditions and at all costs. It is this fact, perhaps, more than any other which has led to the development of relays which operate in conjunction with circuit breakers, the primary object of these devices being to cut out faulty lines or apparatus only when they become a source of danger to the system rather than the protection of the apparatus itself. The large modern unit is much less liable to damage on the occurrence of trouble than were the small sets of a few years back, and although it is certainly desirable to protect all apparatus wherever possible, it is of first importance that the system be kept in continuous operation. For this reason time-limit relays have been developed which do not allow apparatus or circuits to be cut out until they are actually a source of danger.

The ordinary circuit breaker in its simplest form meets usual conditions with a certainty that has made it an indispensable accessory to practically every generating set; but its scope is limited to the function for which it was originally designed, hence, when other conditions have to be met, a suitable relay becomes a necessary addition. The opening of a circuit breaker under no load, overload, reverse current, or under or over voltage may be beyond the powers of the ordinary tripping coil, but any one of these conditions can be effectively met by the inclusion in the circuit of a specially designed relay actuated by the main current and controlling an auxiliary circuit for tripping the circuit breaker. Apparatus to cope with all the above widely different conditions necessarily varies materially in design, and, as will be seen from the following description of a series of direct and alternating current relays manufactured by the British Westinghouse Company, presents many ingenious and interesting features.

Figs. 1 and 2 illustrate two types of overload relay, both of which are operated from series transformers in the main circuit. Usually, they are mounted on the circuit breakers they control, but, if desired, they may be fixed separately on the switchboard. When the main current exceeds a predetermined value the relay contacts close a low-voltage circuit, which actuates the tripping coil of the circuit breaker, causing it to open. It is standard practice to apply direct current to this purpose, but coils can be specially designed for alternating-current tripping if necessary. The type shown in Fig. 1 is constructed on the induction principle. At the base of the slab are two laminated electromagnets, and projecting between the poles

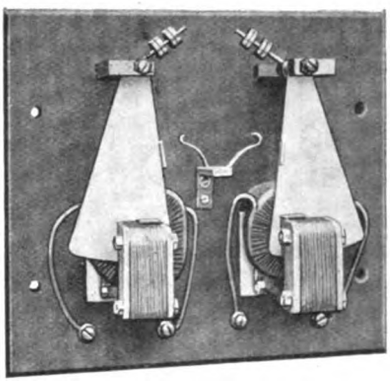

FIG. 1.—Overload Relay, Induction Type.

of each of these is an aluminium sector carrying the movable portion of the auxiliary contact. Part of each pole of the magnet is surrounded by a short-circuited turn of copper, which has the effect of producing a lag in that portion of the magnetic field passing through it, and, therefore, a shifting of the field across the face of the pole. This results in the generation of eddy currents in the aluminium sectors and their repulsion through an angle.

Until the current is of sufficient intensity to make them move, and so close the contacts of the tripping circuit, the vanes are practically stationary, having simply a tendency to deflect. The motion of each sector is opposed by an adjustable weight, as shown, and by means of this the

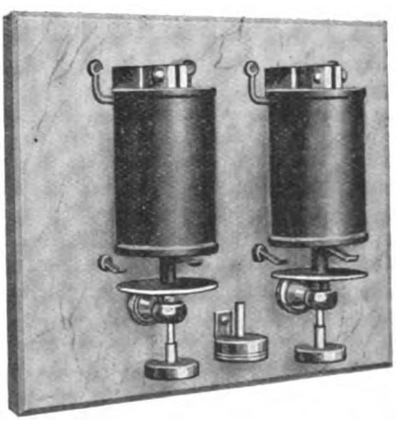

FIG. 2.—Overload Relay, Solenoid Type.

amount of current necessary to close the relay circuits may be varied. The two sectors work quite independently of one another, and either will operate the tripping coil. When used on a two-phase circuit, the movements are connected separately in the two phases through the medium of two series transformers. In three-phase working a series transformer is placed in each phase, and the secondaries are so connected to the relay that it will operate upon the occurrence of an overload in one or all of the main cables exceeding that for which adjustment has been made. For a single-phase circuit, a relay with but one vane is used. This relay is made for high or low frequencies as desired, but it is particularly suitable for high-frequency circuits, and may be connected in series with ammeters which operate from the secondaries of series transformers.

Digitized by Google

It is adjustable over a wide range of action, extending from 80 per cent. to 150 per cent. full-load current.

The method of adjustment by weights and the operation of the solenoid type (Fig. 2) is evident from the illustration. The core of the solenoid carries a disc, which, upon the former being drawn up, closes the auxiliary tripping circuit by means of the contacts shown. Although not confined to them, this type is particularly suitable for low-frequency circuits, but cannot be operated with meters from the same series transformers. The function of a

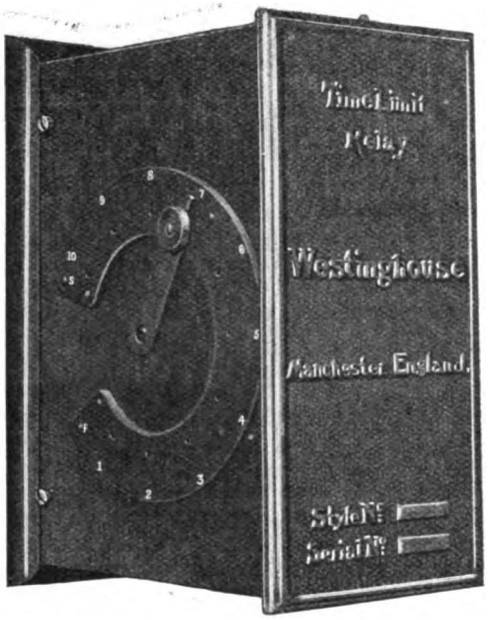

FIG. 3.—Time Limit Relay, Electro-Mechanical Type.

time-limit relay is to allow a certain small interval of time to elapse between the occurrence of an overload or reverse current and the tripping of the circuit breaker. Thus no interruption of the supply will take place if the overload or reverse current does not continue beyond the number of seconds for which the relay is set.

Figs. 3 and 4 illustrate two varieties of this instrument, termed respectively the electro-mechanical and electrical types. The essential part of the former is a spring motor, which is started by an electromagnet placed within the relay, and this magnet may be controlled by a reverse-current relay, an overload relay, by contacts on the circuit breaker, or by a push button. When the overload continues until the end of a predetermined time, varying from two to ten seconds, the auxiliary tripping circuit is closed by

FIG. 4.—Time Limit Relay, Electrical Type.

the spring motor, and the circuit breaker opened; should the overload, however, not continue throughout the time for which the relay is set, it will automatically reset itself, and resume precisely its former condition. With this type of relay it is necessary to keep the spring motor wound up, but it is so designed as to trip the circuit breaker when the spring runs down, and will not allow it to be reset until the motor is wound up The contacts which close the auxiliary tripping circuit will open one ampere at 125 volts.

The electrical type of time-limit relay requires no winding, and consists essentially of a dash-pot, the plunger of which is connected to a moving arm carrying contacts, which move through an adjustable distance to close the circuit of the tripping coil. The motion of this plunger is controlled by an electromagnet placed within the instrument, and the latter may be operated from the main circuit either by an overload or reverse current relay. The predetermined time during which the overload is allowed to continue may be varied from one to five seconds, at the expiration of which period the tripping circuit is closed and the circuit breaker opened. As before, the relay automatically resets itself if the overload is of a shorter nature than that which it is set for. The contacts which close the auxiliary tripping circuit will open 2½ amperes at 125 volts, or a proportionately smaller current at a higher voltage.

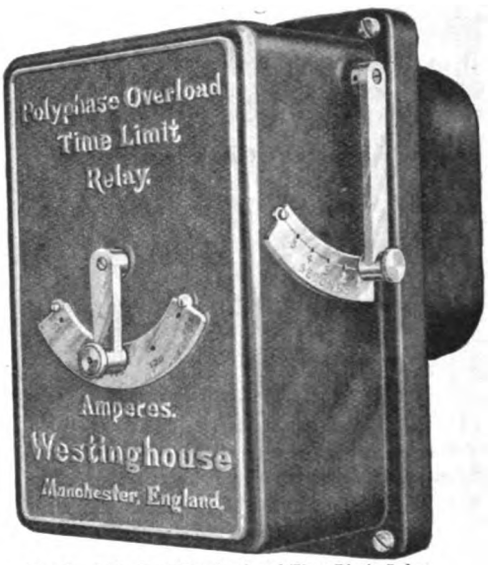

FIG 5.—Polyphase Overload and Time Limit Relay.

The polyphase overload and time-limit relay shown in Fig. 5 consists of a combination in one case of the solenoid type of overload relay and the electrical type of the time-limit relay. It is connected to the circuit containing the circuit breaker by means of series transformers, and is entirely automatic, resetting itself if the overload does not continue throughout the prearranged time, which may be varied from one to five seconds. The overload and time adjustments are made separately by the handles shown in the illustration.

Fig. 6 illustrates a form of direct-current reverse-current relay designed to control circuit breakers the current

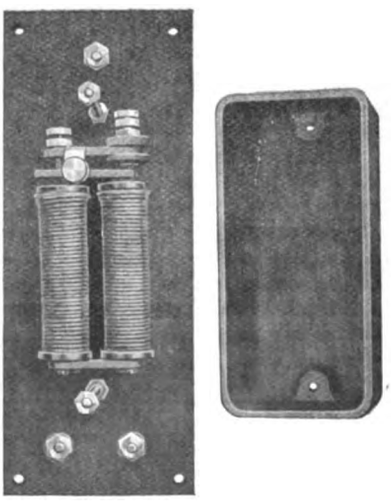

FIG. 6.—D C Reverse-Current Relay.

through which may from any cause be reversed. It is operated by a direct-current instrument shunt placed in the circuit of the circuit breaker controlled by the relay, and the armature and magnet cores are polarised by a permanent magnet fitted behind them. The relay is calibrated to operate on 25 millivolts and to open the circuit breaker on a minimum reverse current of 50 per cent. of the full load of the circuit when energised from one shunt, and on 25 per cent. thereof when energised from two shunts in series. The contacts which close the tripping circuit will

Digitized by Google

open 0·25 amperes at 250 volts, but for high pressures a separate device attached to the circuit breaker should be used. This relay is unaffected by variations of 'bus-bar voltage, and is non-adjustable.

The apparatus illustrated in Fig. 7 is for use with direct current and operates with either overload or reverse current, being adjustable in both cases. The overload range extends from zero up to the maximum capacity of the relay, and the maximum reverse current is one-half of that in the normal direction of flow. These adjustments are made by the projecting rods seen above the scale. This relay acts on the moving-coil principle, the one illustrated being constructed for threading over the 'bus bar. For currents below 600 amperes the construction of the lower part is somewhat different, the apparatus then being connected directly in the circuit.

Mention may be included of two adjustable overload and reverse current relays for single and polyphase alternating-current circuits respectively. These are provided with contacts which close the tripping coil circuit, and are designed to control circuit breakers both when there is an overload on the circuit and when there is a reversal in the direction of flow of power. Thus a circuit breaker equipped with an overload and reverse current relay and connected in a generator circuit will open in the event of the load exceeding that for which the relay is set, and also in the event of the generator, from any cause such as loss of field or failure of the engine, operating as a motor and absorbing energy from the circuit. In order to protect the feeders from overload or short-circuits, it is necessary to use overload relays, usually with time limit, at the generator ends, and reverse-current relays only at the sub-station ends of

FIG. 7.—DC Adjustable and Reverse-Current Relay.

the feeders. By this arrangement any faulty feeder would be entirely cut out and the supply maintained. Both these instruments work on a principle similar to that of the induction wattmeter, and are operated from series and shunt transformers. The working range is adjusted by rotating the drums on which the scales are mounted until the required value is opposite the fixed pointer. Ordinarily direct current is used for tripping the circuit breaker, but coils can be specially designed for alternate-current tripping.

An auxiliary relay switch is supplied for use with any of the above-mentioned types of relay in cases where the current required to trip the circuit breaker is greater than that which the master relay can carry. It is of the solenoid type, the core carrying a disc which closes the tripping circuit through brush contacts. These relays are designed for intermittent service on direct-current circuits, and one such device may be used to operate two or more circuits breakers at the same time if necessary.

## THE METALLIC ARC.*

BY ISADOR LADOFF.

The numerous attempts which have been made to utilise the electrolytic arc as a source of light have not thus far led to any technical success. The fundamental idea of all these attempts consists in the combination of the oxides possessing luminiferous properties with non-luminiferous but more conductive oxides. Some investigators have even gone so far as to make the surfaces of the pencils conductive by surrounding them with a metallic tube or by reducing the oxides *on the surface* to a metallic state.

Experience with titanium oxide as an electrode indicates that it is by far the best luminiferous material so far known. Like other oxides of that nature, however, it is a poor conductor of electricity at the usual temperature. A series of experiments with a combination of titanium oxide with iron oxides has been conducted with more or less unsatisfactory results. The magnetite used contained impurities which caused a great deal of annoyance. The pencils were extremely brittle and had to be protected with iron tubes. These tubes served a double purpose, since they protected the pencils from breakage and made them sufficiently conductive. The disadvantages of the tubes were numerous. The pencils were very clumsy in appearance. The arc flickered badly and gave yellow streaks of low luminous power every few seconds. Attempts to improve the properties of the pencils by reduction of the surface of the electrode or electroplating it with iron or copper met with failure. The partial reduction undoubtedly increased the flickering of the arc and did not reduce the extreme brittleness of the pencils. The proportions of the ingredients of the pencils were about 80 parts of magnetite, about 20 parts of hematite, and about 7 or 8 parts of titanium oxide. If more than 10 parts of titanium oxide were added to the mass of the electrodes, a very unquiet and flickering arc was produced. The resistance of baked pencils having a diameter of about 0·5in. and a length of 5in. was from 44,700 to 624,800 ohms. When covered with a thin film of graphite the resistance of the same electrodes fell to 4 88 ohms or 6·24 ohms.

In order to determine the difference in the behaviour of the pencils with change in their conductivity, a number of them were partially reduced in carbon at 1,150deg. C. Their resistance varied from 11 to 28 ohms. Pencils heated without carbon at the same temperature showed a resistance varying from 594,000 to 9,830,000 ohms. As the degree of reduction seemed to play some obscure rôle in the arc, a few experiments were made to determine the influence of the process of oxidation in the arc. Electrodes for these experiments were prepared in the usual way and manner. One batch contained the usual proportions of hematite and magnetite. The second batch contained no hematite whatever. The third batch was free from magnetite. Each of the three batches contained an identical quantity of titanium oxide (of 7 5 parts), and each was treated at the same time under exactly the same conditions as far as practical. The most luminous arc was produced by the pencils containing only magnetite and titanium oxide. The least luminous arc was obtained with the pencils composed only of hematite and titanium oxide. The mixture composed of 80 parts of magnetite and 20 parts of hematite gave an arc of medium luminosity. As hematite represents the final product of oxidation of iron, it was concluded that oxidation is a factor favourable for the luminosity of the arc—that is, the more space there is left for the oxidation of the material of the electrodes in the arc the better must be the luminosity of the arc.

For the purpose of verifying the above conclusion, additional experiments were conducted. Electrodes of the identical batch were subjected to various degrees of reduction, and the luminosity of their arc tested. In each case the more reduced pencils gave a higher luminosity, and the luminosity of the perfectly reduced pencils was about double the luminosity of the pencils which had not been reduced. A batch containing 50 per cent. of magnetite and 50 per cent. of titanium oxide was subjected to various degrees of reduction, with the following results, the candle-power referring to horizontal measurements:

Well-reduced pencils produced an arc of a luminosity equal to 1,271 c.p.; partly-reduced pencils produced an arc of a luminosity equal to 1,000 c.p.; poorly-reduced pencils produced an arc of a luminosity equal to 868 c.p.; pencils not reduced produced an arc of a luminosity equal to 700 c.p. The current used was a direct one of 3·4 amperes, with 105-110 volts drop across the arc.

The reduction not only increased the efficiency of the

Digitized by Google

arc by 100 per cent., but it allowed the use of high percentages of titanium oxide in the mass of the pencils. In the partially-reduced pencils an addition of more than 10 parts of titanium oxide was excluded, because such an amount caused the arc to flicker to an extent such that photometric reading could not be taken with any degree of accuracy. The arc of the reduced pencils was quite steady when even as high as 90 per cent. of titanium oxide was used with 10 per cent. of magnetite. There appears, however, to be a limit beyond which any further addition of titanium oxide ceases to be advantageous. The best results were obtained with pencils containing about 50 per cent. of titanium oxide and 50 per cent. of magnetite. The perfectly reduced electrodes are metallic throughout. They are harder than tool steel and take an excellent polish. When ready for use they look like ordinary steel cylinders. Obviously any luminiferous substance may replace the titanium oxide, and any metallic oxide may be substituted for the iron oxide. For instance, magnesium oxide could be combined with an oxide of copper, and then reduced to metallic state.

Additional experiments with the metallo-electrolytic arc indicated that an alloy of titanium with a well-conducting metal like iron, copper, etc., would furnish an ideal material. Various samples of titanium alloys were used for pencils for the electric arc. The results more than justified the expectations. Comparatively small quantities of titanium alloyed with other metals obscure the spectrum of the last, and produce an arc whose luminosity is entirely out of proportion to the quantity of titanium contained in the mass of the pencils. Alloys of other metals whose oxides are distinguished by their high luminosity in the arc—as, for instance, magnesium, zirconium, etc.—withnon-luminiferous but conductive metals produce similar results. It is believed, therefore, that the work here briefly outlined opens a new field for the metallo-electrolytic arc as a source of light of the future.

In order to ascertain the practical value of the new arc, Messrs. L. B. Stillwell and H. S. Putnam were requested to make a report upon the subject, and the following samples were submitted for test: B—two pieces marked F T., 80 per cent. ferro-titanium; C—one piece marked 4·1 L, 30 per cent. rutile, 70 per cent. magnetite; E—½in. plain carbon, moulded. The following description of the tests conducted is abstracted from their report. The results of the candle-power measurements and life tests of the ferro-titanium (B) and rutile (C) pencils, as well as a test made with plain open-arc domestic carbons, are summarised below. These tests are principally valuable as illustrating the nature of the pencils, and relative illumination and life as compared to an ordinary carbon when operated under the same conditions. The results as tabulated are the averages obtained by omitting such measurements as were abnormal in the judgment of Mr. Putnam, who conducted the tests:

RESULTS OF TESTS WITH HAND-FED ARC LAMPS.

The results given were for the most part obtained with the positive carbon pencil placed at the top. The results with a positive copper pencil at the top were slightly, though not materially, lower in candle-power, and they have been averaged with the other results obtained.

The positive copper pencil is evidently not consumed in the arc when used in connection with the titanium pencils. There is a slight loss in weight, due probably to oxidation and scaling at the surface of the copper owing to its high temperature.

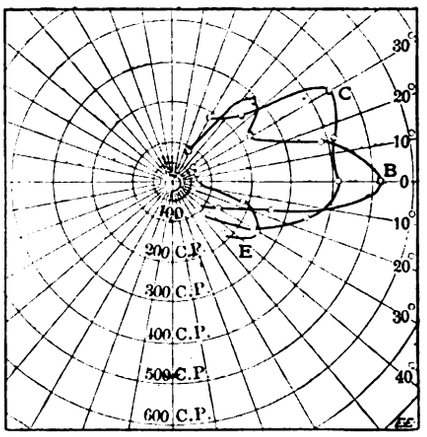

FIG. 1.—Distribution of Luminous Intensity.

The rutile pencil was further tested as a constant-potential arc lamp operating on a current of approximately 4·5 amperes. In this lamp the rutile pencil, C, was placed below and an ordinary carbon above, and the test made first with the carbon as a negative and then with it as a positive. Two sets of measurements were made, one at approximately 60 volts, and the other at 70 volts. The results are tabulated below.

| At 60 volts. | Carbon upper −. Rutile lower +. | Carbon upper +. Rutile lower −. | Rutile upper +. Rutile lower −. |
|---|---|---|---|
| Mean spherical candle-power | 544 | 448 | 624 |
| Watts per candle-power | ·521 | ·60 | 41 |
| Amperes | 4·52 | 4·18 | 4·25 |
| Volts | 62·8 | 64·8 | 61·2 |
| Watts | 283·9 | 270·9 | 260·1 |

| Length of arc—inches (estimated) | ·375 | ·875 | ·75 |

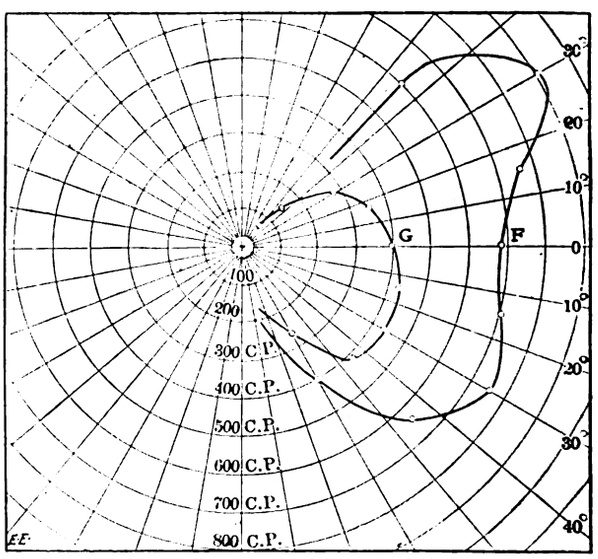

FIG. 2.—Distribution of Illumination.

The light distribution in the tests of the ferro-titanium, rutile, and carbon pencils at 3 5 amperes and from 50 to 55 volts is shown in Fig. 1. The light distribution of the test of the rutile pencil in a constant-potential lamp at 4·2 amperes and 70 volts is indicated by Curve G on Fig. 2

Digitized by Google

All candle-power measurements were made on the arc photometer designed by Prof. C. P. Matthews. The life of the pencils is computed from a burning test of from 1½ to 2 hours, the pencils being first burned to shape and then weighed in a chemical balance before and after the test.

For purposes of comparison, in Fig. 2 has been plotted a curve, F, taken from the report of Prof. Matthews, included

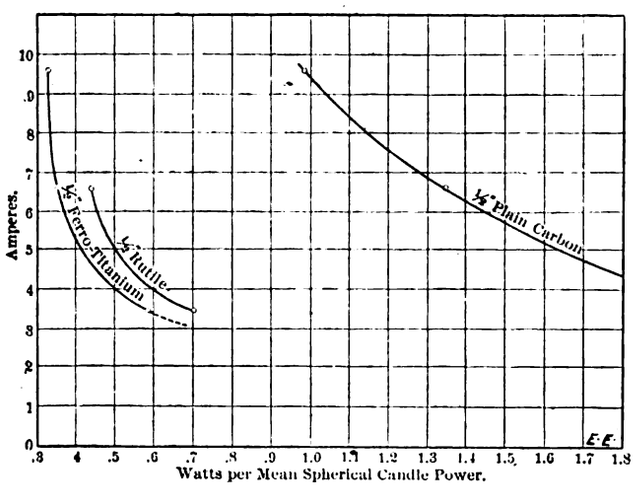

FIG. 3.—Efficiency Curves.

in the report of the Committee on the Photometric Measurements of Arc Lights to the National Electric Light Association, May 20, 1902. This curve is the result of many measurements, and represents the light distribution of the ordinary series enclosed arc lamp in common use in this country for street and interior illumination. The measurements were made on a constant current of 6·8 amperes, with 70 volts at the arc, with an opalescent inner and a clear outer globe. The series enclosed arc lamp gives 303 mean spherical candle-power at 476 watts, or 1·57 watts per mean spherical candle-power. It burns approximately 100 hours for one trimming.

The light produced by ferro-titanium and rutile (oxide of titanium and magnetite) pencils is pure white as judged by the eye. The spectroscope shows the entire solar spectrum with especial brilliancy in the bright yellow portion and in the neighbouring light green and orange.

The arc itself presents many peculiar characteristics and assumes different forms under different conditions. The normal arc with a positive copper or carbon pencil at the top and the ferro-titanium or rutile pencil below is approximately ⅜in. in length at from 50 to 55 volts, and increases to ¾in. or ⅞in. at 70 volts. It is from $\frac{3}{32}$in. to ⅛in. in diameter and emanates from the titanium pencil. At the higher voltage the arc is unstable, and is easily broken. At from 50 to 55 volts the familiar sound of a 'hissing" arc is produced. As the voltage and the length of the arc are increased this sound is diminished, and the only sound produced is similar to that of escaping steam, which, however, is not of an objectionable character. Under both of the above conditions of operation the point of contact of

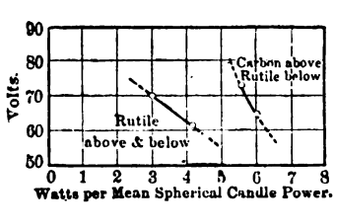

FIG. 4. Efficiency of Rutile and Carbon Lamps.

the arc with the upper and lower pencils is constantly in motion, causing a flutter in the light emitted. This feature is largely eliminated with a long arc.

As already mentioned, when the titanium pencil is made the negative and placed at the bottom, at 70 volts the arc is from ⅜in. to ⅞in. long and about ⅛in. in diameter, and of an unusually white colour, slightly more light being produced at or near the surface of the electrodes owing to the concentration of the arc and the incandescence of the surfaces. The arc itself is clean cut and well defined, and is a true arc and not a "flaming" arc, as is generally understood by that term. The same results were obtained with either a copper or carbon positive. As the arc fluttered and shifted, the apparent trend, with the gases and material carried by it, under normal operation, was from the negative to the upper positive pencils. Under the same conditions, but with the direction of the current reversed—that is, the lower titanium pencil made the positive—an arc of entirely different character was obtained. The diameter of the arc was increased from ⅛in. to ¼in. or $\frac{5}{16}$in. At the same voltage the length was also slightly increased, approximately to 1in. The "flutter" was absent, although the arc lazily shifted from one point to another. The direction of the arc seemed still to be from the lower positive to the carbon or copper negative above, but possessed but very little illuminating power, and had a decidedly reddish tinge. Frequently, for short intervals, the arc became suffused with the white light characteristic of titanium. On account of its steadiness, lack of "fluttering," and very large diameter and length, the arc presents many attractive features.

By placing the titanium pencils on both sides of the arc and making the upper electrode positive, there was obtained a third type of arc having a distinctly different character. Though differing from either, it seemed to be practically a combination of the two above mentioned. The arc resembled an inverted cone, having its apex on the lower pencil and its base on the upper pencil. Through the centre ran a core fairly representing the arc obtained in the first case mentioned above. Around it was a zone representing the second arc described, but of a diameter increased to possibly $\frac{5}{16}$in. or ⅜in., and suffused with the white titanium incandescent gases. The arc as thus obtained was absolutely steady, with no "fluttering" or shifting. Both upper and lower pencils were fused at their surfaces, but, contrary to expectations, the molten material from the upper pencil did not drop. The light is softened somewhat by the presence of what might be called the negative arc, but possesses all the colour characteristics of the titanium arc. The measurements made of these three arcs have shown that the candle-power efficiency at 70 volts is nearly doubled by placing a titanium pencil above as well as below. There is such an excess of incandescent vapour provided in this form of arc that apparently very promising results could be obtained with a longer arc. An efficiency of ·3 watt per mean spherical candle-power was obtained in this test, and it seems entirely probable that this can be improved. Fig. 3 shows the watts per mean spherical candle-power obtained at 50 volts approximately, with ½in. pencils, and at various current values. It is apparent from these curves that very little increase in efficiency results from an increase of current above 6 amperes under the conditions observed in the test—namely, with ½in. pencils, and about 50 volts at the arc.

In Fig. 4 are plotted the results obtained at 60 and 70 volts with a rutile lower negative and a positive electrode of carbon and rutile respectively. Unfortunately, the number of observations were not sufficient to construct a reliable curve, but the sheet indicates graphically the great increase in efficiency due to using a titanium positive as well as negative, and from the direction of the curves it indicates that an increased efficiency would be obtained at a higher voltage, especially in the case where the titanium is used for both positive and negative electrodes.

The light produced by titanium pencils is agreeable to the eye and pure white in colour, and produces the entire spectrum, with especial luminosity in the yellow zone. The luminous efficiency of titanium pencils is very high. At corresponding current values and voltages the energy consumption per mean spherical candle-power is from one-third to one-fourth of that required by carbon electrodes. The light from the titanium arc, as shown by the distribution curves, is produced in about equal amounts above and below the horizontal. It will be necessary, therefore, to use a lamp with a reflector to obtain the best results of illumination. When operated under proper conditions the life of the titanium pencils is much greater per inch of material than carbons. The rutile pencil gives longer life than the ferro-titanium, and with the former there is no doubt that a pencil can be designed to give a life as long as that of

Digitized by Google

the present enclosed arc lamp. A much longer life seems possible.

The luminous efficiency of the ferro-titanium pencil is higher than the rutile, but the difference is so slight that the superior life of the rutile makes it more desirable. Very superior results are obtained by using titanium pencils in both electrodes. While objections to this might be revealed by further investigation, or an electrode of some other material might be found to give equally good results, this method of operation offers a promising field for investigation.

## IMPERIAL NOTES.

### New Zealand.

*City of Wellington.*—We are pleased to give herewith a very satisfactory account with regard to the undertaking of the City of Wellington Electric Light and Power Company, Limited. The results, indeed, are a glowing testimony of the ability of the resident engineer and manager, Mr. G. S. Maben, and must be highly gratifying to all concerned. Let it be remembered that Wellington, although it assumes the proud distinction of city, with all the dignity attaching thereto, has a population of some 40,000 souls only. Yet the consumers taking a supply of electricity from the company's mains numbered the extraordinary total of 2,921 at the time when the accounts for the past year were closed, and are increasing at the rate of about 250 per annum—the approximate equivalent of 10,000 8-c.p. lamps. This, it may be remarked, has been the actual average increase during Mr. Maben's three years' residence on the spot. The total number of 8-c.p. lamps, or their equivalent, connected to December, 1904, was 96,380. Included in this figure are 33 15-ampere open-type arcs and 900 20-c.p. 200-volt incandescent lamps used for public lighting; also 706 h.p. of motor load. The total number of units generated for 1904 was 1,674,532—1,200 kw. representing the maximum demand. Turning to the financial side, we find that the results have been no less satisfactory. Thus out of a total revenue of £34,106. 7s. 9d. the expenditure amounted to £16,737. 15s. 4d., leaving a net balance on the year's working of £17,368. 12s. 5d. In comparing these results with those obtained in the old country, the different conditions must, of course, be taken into account. Judging from the fullness of Mr. Maben's success, it might be assumed he has no gas competition to contend with, but that is not so; the results quoted having been obtained in the face of opposition, so much more the credit. With regard, however, to the net profit, it must be remembered that the purchasing value of money is considerably less in New Zealand than here, hence a smaller return, say, at Darwen, Ealing, Exeter, or any other town having approximately the same population, would represent an equivalent value. But even making due allowance for the difference, a search through "The Electrical Engineer's Central-Station Directory" fails to discover a single record of equal success in the old country.

The relatively small purchasing value of money in Wellington is eloquently reflected by the detailed costs of working the undertaking. Thus we find that 16s. 9d. per ton is paid for coal—the equivalent of that at about 4s. 6d. per ton in the North of England. The wages of greasers and stokers amounted to £2. 16s. per week of 48 hours, those of the charge engineers ranging from £6 to £3. 10s. per week. The works cost averaged 2·60d. per unit generated for the year, and the total costs 3·21d. Having regard to these figures, the readers will not be surprised to learn that 1s. with a sliding-scale discount is the price charged per unit for lighting, while 3d. per unit is charged for power, heating, etc. The average price obtained per unit was 6·20d.

It may not be out of place to add a few particulars here of the system and plant installed. An alternating-current supply is given. This is generated at 2,000 volts, 80 periods, and subsequently reduced to 200 or 100 volts for distribution. The steam-raising plant comprises six watertube and four Economic boilers by Babcock and Wilcox and Davey-Paxman respectively. These boilers work in conjunction with Green's economisers and supply steam at 160lb. pressure to three 400-h.p. Browett-Lindley triple-expansion and tandem compound engines, coupled to a like number of 300-kw. Westinghouse alternators; one 350-h.p. marine Brush engine, coupled to a 250-kw. Mordey alternator; one 200-h.p. Universal Brush engine, coupled to a 150-kw. Mordey alternator; and three 150-h.p. horizontal Davey-Paxman engines driving three 75-kw. rewound Gulcher machines. Separate exciters are provided. Variety is certainly not lacking here, nor is it absent outside the station, where overhead distributors are the order. The mains and distributor cables have been supplied by no less than four different firms—The British Insulated and Helsby Cables, Limited; Glovers, Limited; Callender's Cable and Construction Company, Limited; and the India Rubber, Gutta Percha, and Telegraph Works Company, Limited. It may be also noted that the total capacity of transformers installed is 2,750 kw. Supply was started in 1891.

It is satisfactory to learn that the use of electricity, both for lighting and power purposes, is going ahead steadily throughout New Zealand. All the large cold storage companies are adopting electric driving. By recent legislation, however, the Government have reserved all water power for themselves. This has caused many private schemes to be dropped.

### Cape Colony.

*King William's Town.*—Good progress is reported in regard to the King William's Town electricity works. The Corporation took over this undertaking in February last, the event being marked by much rejoicing in local circles. Previously it had been worked by a company for 15 months. The plant is not a large one at present, but is being extended. In the latter connection it is interesting to note that the high-tension feeders became fully loaded during the first winter's supply, due to consumers coming on at a much faster rate than had been estimated. The company in whose hands the undertaking then was ordered an additional feeder cable. This is now being laid by the British Insulated and Helsby Cables, Limited. As regards the extension plant since ordered by the Corporation, this includes a new Belliss-E.C.C. 100-kw. steam alternator, a Davey-Paxman Economic boiler similar to the two already installed, and four 20-kw. Ferranti transformers. The primary current is generated at 2,100 volts, 50 periods, being transformed down to 220 volts for distribution. The high-tension feeders are laid underground to sub-stations, whence the distributors (No. 0 S.W.G.) are carried overhead. It is understood that the Corporation will as soon as possible reduce the charge per unit for the supply. They do not seek to make any very great profit out of the undertaking for the purpose of applying it to other works. We congratulate the resident engineer, Mr. G. E. Sanders, on the satisfactory state of things above recorded. He is the man to whom the principal credit is due.

## INSTITUTION OF ELECTRICAL ENGINEERS.

### Stand-by Charges and Motor Load Developments.

BY A. M. TAYLOR.

The paper on the above subject was read by Mr. Taylor before the Birmingham Local Section on Dec. 14 last, and we reproduced in our issue for Jan. 15 an abstract of the same, with some interesting diagrams to show how the cost of supply in a station varied with the machinery in use. This paper has been rewritten and amplified for discussion before the parent Institution, to which it was presented last night. In his introductory remarks the author gave the following *résumé*, which can be read in amplification of our previous abstract. He stated that: The present paper starts with the assumption that existing prices for power from small stations are prohibitive, as far as the capturing of continuous loads is concerned; and that where they are not prohibitive they are unsound, except in a few favoured towns where the motor load does not clash with the lighting load. Analysis is made of the charges to be levied per unit for two classes of motor, representing extremes in load factor—viz., class 1 having 30 per cent. load factor and class 2 a 7½ per cent. load

A.—Works cost.
B.—Interest and sinking fund at 7 per cent. on "productive" capital only.
C.—Maintenance, salaries, and office expenses.
D.—Rates, taxes, etc.
E.—Net profit.
F.—Selling price.
* Reduced from ·70d. by subtracting "stand-by" losses.
† Reduced from ·95d. by subtracting "stand-by" losses.

factor. The investigation is first made into charges for what are called "interest-paying motors"—*i.e.*, motors which are charged a sum to cover interest and sinking fund on new generating plant and mains rendered necessary by the over-lapping of the lighting and motor loads. The results are given in the columns 2 and 5 of Table A. A suggestion is then made to sell power at extremely low rates on the basis of the current being cut off during "peak" hours.

The generating plant having thus been protected so far as the regular evening peak is concerned, the question arises as to how far a day fog may endanger the lighting supply from the station. A case of quite phenomenal motor load development is worked out in detail, and the results as plotted show, the author thinks conclusively, that in any provincial town it would be perfectly safe to offer the suggested low rates without any danger of a day fog causing the lighting to be shut down; and even in London the system could be worked at the same rates if due precautions were taken to protect the lighting. Means are also indicated in the paper for further extending the load which might be taken up, should the development be exceptionally rapid.

Stand-by charges are next considered, and possible improvement in the works cost, due to the elimination of these, is worked out. Results so obtained are then combined with the other reduced charges consequent on supplying the additional units on the "restricted hours'" system, and are tabulated on columns 3 and 6 of Table A. The "restricted hours' system" has the advantage over a two-rate meter system that a much lower price can be offered, because with the former no material expense whatever, either in plant or mains, has to be incurred; whereas with the latter it would seem that an extra charge must be levied on all units, and not only those which are inside the limits of the peak, otherwise the charges on the latter would probably bring them above even lighting charges. In Montreal, where consumers of class 1 are charged respectively 1·24d. and 1·60d. per horse-power for "restricted hours'" and "unlimited hours'" supply (the flat rates are £10 and £21 per horse-power per annum), some 30 per cent. of the horse-power connected is voluntarily taken up on the former basis out of a total of 21,000 h.p. connected to the mains. If only half (with the greater reduction in price this should certainly be exceeded) this proportion were to hold for the 500,000 h.p. which, we are told, is going to the lowest bidder in London, there would be 75,000 h.p. in London which could be obtained on the "restricted hours'" system at the present time without a penny being spent in generating plant.

Taking account of the fact that they are essentially manufacturing towns, it is probably safe to say that in, let us say, Birmingham there must be quite 15,000 h.p. and in Sheffield 12,000 h.p. similarly obtainable, and in other towns in proportion. Will anyone maintain that this load is so insignificant as to be not worth the catering for? And would it not bring in its train quite a large proportion of "interest-paying" motors.

A suggestion is made for tiding over the peak load by a special arrangement of accumulator cells on consumers premises. The author has ascertained that responsible accumulator makers would be prepared to maintain cells, under the conditions stated, at not more than 10 to 15 per cent. of the capital cost per annum. Another table shows that on this basis a municipal electric lighting station could offer power at charges which would be of the order of only 50 per cent. of their present rates, or of only 60 per cent. if the maintenance rates were doubled. The author suggests that the "restricted hours'" system at ½d. to ⅝d. per unit, supplemented by the private battery system at ½d. per unit additional, will be found to provide a means for obtaining a class of load hitherto out of reach. The system might also be used to "prospect" for battery sub-stations.

The result of some later figures collected by the author relative to costs of gas suction plants for small powers are given in an amended table to replace Table C in the paper as circulated.

## Systems of Electric Units.

A discussion on "Systems of Electric Units" was initiated at a meeting of the Institution on the 6th ultimo. by Mr. W. H. Duddell, hon. secretary of the delegation which attended the St. Louis Congress, at which this subject was considered. The papers presented on that occasion by Profs. Ascoli, Giorgi, Carhart, Patterson, and Wolff were embraced in the present discussion.

Digitized by Google

Mr. DUDDELL first drew attention to the question, What is the true value of the volt and ampere? It was pretty generally admitted that the true value of the volt ($10^8$ C.G.S. units) was such that the E.M.F. of the Clark cell at 15deg. C. was very much nearer 1·433 volt than 1·434 volt, the present legal value. From some recent experiments made by Mr. Trotter at the Board of Trade it appeared that the voltage of the normal Clark cell, determined in terms of our "standard" ampere and ohm, was nearly one-tenth of 1 per cent. less than the legalised value, so that there was a discrepancy between our legal standards of nearly one-tenth of 1 per cent., though this did not exceed the limits of error set forth in the Order in Council. As the volt, ampere, and ohm are connected by Ohm's law, if standards are fixed for any two the third is determined in terms of them. Accepting the present ohm, it is only necessary to legalise a standard to represent one of the other two. Was it better to adopt a standard to represent the volt or to represent the ampere? If a standard for the volt is adopted, it would probably be in the form of a cell. Was the Clark (Zn) cell or the Weston (Cd) the more suitable? If the ampere be adopted, is the silver voltameter the most satisfactory form for this standard, or should some form of current balance be used? The various countries which have made laws on the subject of electrical units have adopted different definitions for units, although the definitions are apparently intended to specify the same unit. Thus the legal definition here in Great Britain states of each unit that it *has the value* in terms of the C.G.S. and is *represented by* a certain concrete standard, whereas in the United States law the definition of the unit in terms of the C.G.S. system is qualified by the word *substantially* equal, which suggested the question, Should the legally-defined fundamental units be the C.G.S. units or those obtained by assigning values to the concrete standards? He then defined the various kinds of standards we require. He thought that for each of the electrical quantities we need three standards. First, the fundamental standard, which, he thought, all were agreed must be the C.G.S. This, however, is not a concrete standard. Second, a concrete representation of the fundamental C.G.S. standard or of a multiple of it. Third, the practical standard to be used in everyday work. Regarding magnetic units, Mr. Duddell stated that we require for practical purposes names for three magnetic units—viz., magnetomotive force, total flux, and reluctance. Here, again, there were three courses open in the choice of the magnitude of the units to be named. Firstly, there are already seven units with names in the practical—or volt-ampere-ohm—system. To these might be added three consistent magnetic units, such that the time rate of change of the flux would be in volts, the magnetomotive force would be $4\pi \times$ ampere-turns, and the unit of reluctance the quotient of the unit of magnetomotive force divided by the unit of total flux. Secondly, names might be conferred upon the so-called "rationalised" magnetic units which would involve moving the $4\pi$ from the magnetomotive force to the reluctance. Thirdly, the C.G.S. units could be given names. The question he wished to submit was, Shall the $4\pi$ be moved? Or, if not, Shall the C.G.S. magnetic units or those consistent with the volt-ampere-ohm system be given names? It had been suggested that all the C.G.S. units needed names. If this were so, how ought these names to be formed? The Chamber of Government delegates to the congress had resolved to advise their respective governments to appoint a permanent international commission to deal with these questions of units and standards, and it was greatly to be hoped that this excellent recommendation may be carried into effect. In this event there was one final question he wished to put, Can this Institution, which represents the great body of electrical engineers in this country, help the commission in any way by collecting data from its members by having experiments carried out, and by bringing the results before the commission?

Mr. R. K. GRAY reviewed the history of the delegation to St. Louis, and alluded to the kind treatment received at the hands of their American friends, which he thought was very gratifying in these days of strenuous competition. The opinions of the British delegates were received with great deference.

Lord RAYLEIGH first dealt with the employment of the volt or the ampere as the second principal standard. It seemed to him that too much had been taken for granted in regard to there being no residual uncertainty respecting the ohm. Had we been given the ohm from Heaven there would be a great deal in favour of accepting the volt as the other standard, but, as it was, the uncertainty respecting the ohm might be accentuated by taking the volt as the other standard. He appreciated the convenience of the cell from the practical point of view, and doubtless it would still be used in the workshop as a tertiary standard in any case. At the present time we certainly knew the ohm more accurately than the volt or the ampere, but research might alter this. Before long we might be able to concentrate attention on the advantage of the Weston over the Clark cell in regard to lower temperature coefficient. As the uncertainty found in the setting-up of the Clark cell at the mercury end was in a fair way to being solved; but it would be advisable not to supersede the older cell precipitately. He thought it might be as well to leave the $4\pi$ question in the hands of the rising generation. He hoped electrical terms would not be unduly multiplied, as it was liable to be a tax upon the memory of those who were engaged in other fields as well.

Prof. AYRTON recalled the discussion at St. Louis, when an important point was entirely omitted—viz., the degree of accuracy with which the ohm was known. He then tabulated the best determinations of the ohm that had been made in this country, specially detailing the researches of the late Prof. Viriamu Jones. As a matter of fact, this had not been definitely determined to a fifth decimal point—indeed, it was not absolutely known to a fourth point. It was quite immaterial that the resistance of coils in this country might be found to agree with those in Germany to one part in 100,000. This simply showed the possibility of making coils to a high degree of similarity in resistance. Perhaps the gift of £700 by the Drapers' Company for the construction of a new Lorenz apparatus for use in the National Physical Laboratory would enable a more accurate determination of the ohm to be made in a year or two. It was impossible to determine the volt absolutely in electromagnetic measure, though it could be done in electrostatic measure. The result of the latter could not, however, be converted into volts unless they knew the ratio of the electromagnetic and electrostatic unit of quantity, which was just as difficult to obtain as a determination of the ampere or the ohm. On the other hand, it was possible to determine the ampere to a very high degree of accuracy, and he had been greatly surprised that the last 30 years had seen no practical redetermination of it. In all these absolute measurements it was essential to know the position of the wire coils that were carrying current, and consequently there must be only a single layer of wire for the stationary coil in which the metal disc rotated. He hoped, through the apparatus in course of construction by Dr. Glazebrook and himself, to determine the ampere with certainty to one part in 10,000, and possibly in 20,000.

Mr. A. P. TROTTER, who prefaced his remarks by stating that they must not be taken as representing the official view of the Board of Trade, dealt with the distinction between a unit of E.M.F. and the standard of E.M.F. He quoted the following statement from Dr. Wolff's paper on "The Legalisation of the Electrical Units by the various Governments," read before the St. Louis Congress: "In England . . . a distinction is made between a unit of E.M.F. and the standard of E.M.F., the latter being defined as the one-hundredth part of the pressure producing a certain deflection of a Kelvin electrostatic voltmeter of the multicellular type . . ." Mr. Trotter instanced the British standard yard and the metrical unit of length. When the metallic bar representing the British standard yard was lost by the burning of the Houses of Parliament, the new standard was constructed, not by any scientific determination, but by a careful comparison between the best scales available. Similarly, the metre, as a practical standard, was represented by the platinum bar kept at Paris, irrespective of its definition as the metrical unit of length. A standard was, in fact, the material embodiment of a unit for practical purposes. The Order in Council of 1894 kept a clear distinction between a unit and a standard. Unlike any other country, the limits of accuracy attainable were declared by an Order in Council, which used the expression "is represented by," whereas in the United States, Germany, France, and Belgium the regulation read "substantially equal to," or similar words. Subsequently it became necessary to define the units, but it seemed to the speaker that, now that so much work had been done on absolute electrical measurements, if we were starting afresh, the C.G.S. definition would suffice for the units, leaving the selection of standards to the officials of each country. Mr. Duddell had spoken of units as primary standards, and of what he (Mr. Trotter) called standards as "secondary standards." Mr. Trotter quite agreed that it would be unwise to tie ourselves too tightly to these. If it were found that the standards diverged appreciably from the units, two courses were open to "scrap" the standards or to apply a correction. Clerk Maxwell considered that the original British Association ohm would not be altered, but that a correction would be applied when more accurate researches had been made. Alluding to the important work undertaken by the National Physical Laboratory in determining the absolute value of the ampere and of the ohm, the Board of Trade might or might not take official action in declaring a correction; but the result would be well known to the scientific world, and anybody could apply the correction for himself. At present there was no reason to suppose that the standards of this country differed from the units by more than the limits of accuracy which had been laid down. Suggestions had been made that the method of silver deposition described in the specification attached to the Order in Council was capable of improvement, but the method was not introduced for the purpose of defining the ampere by means of the electro-chemical equivalent of silver. A discrepancy between the declared and the observed value of the Clark cell had been discovered, and he had taken steps to let it

Digitized by Google

be known semi-officially that the value appeared to be 1·4329 instead of 1·434 at 15deg. C. For work of the highest accuracy he preferred a saturated cell with a higher temperature coefficient to a semi-saturated cell with an almost negligible temperature correction. He was not prepared to recommend the Board of Trade that any amendment of the Order in Council was necessary, but if any amendment were made he would prefer that the definition of the volt should not contain reference to the Clark or any other standard cell, but that we should fall into line with Germany, Austria, Belgium, and Switzerland.

Mr. F. E. SMITH commented upon the consistency of the concrete mercury ohm, which appeared to be reproducible to within two or three points in 100,000. He had found that the value of the mercury ohm was subject to slight fluctuation, and he might add that the mercury standards of the National Physical Laboratory were not permanent, nor, he thought, was it desirable that they should be. Platinum potential leads must be led into the mercury, and it was impossible to say to what extent the platinum would go in solution in the mercury, and what effect that would have on the resistance. He concurred in the views expressed at St. Louis by Dr. Wolff and Prof. Carhart upon the standard cell. As, however, standard cells changed very gradually in E.M.F., they must be kept under observation for years, and so far no cadmium cell had been observed for the requisite period. If made in accordance with the new specification and maintained at a constant temperature, the Clark cell provided an excellent secondary standard, but for practical purposes the cadmium cell was preferable on account of its low temperature coefficient.

On the discussion being resumed on April 13, Dr. R. T. GLAZEBROOK, F.R.S., corroborated the importance of the point made by Lord Rayleigh that a determination of the ampere does not involve knowledge of the ohm, whereas a determination of the volt does require that knowledge. At St. Louis, however, the delegates were concerned with concrete standards for practical use which should be universally acceptable; and since the ohm, defined by the length of a certain column of mercury, was universal, it was felt that that fact might be taken as established, and that definitions of further quantities required might be based on it. Dr. Glazebrook then expressed his complete agreement with the remark made by Mr. Trotter, that as the concrete standards for England are certain instruments deposited at the Board of Trade laboratory, we are, so far as such standards are concerned, independent of their exact relationship to the fundamental C.G.S. units. At the same time he pointed out that the standards had been constructed originally with reference to the C.G.S. units, and were supposed to represent certain multiples of them, depending thus on the mercury resistance (with which the committee recommended that the standard ohm should be compared), the electro-chemical equivalent of silver, and the E.M.F. of the Clark cell. Other nations had endeavoured to set up standards depending also upon these units, with the result that in consequence of more recent investigations their concrete standards no longer agreed with the English. As to the practical need of any change, it had been pointed out at St. Louis that while the difference of a tenth of a volt only made an error of ·5 or ·6 in the candle-power of a 16-candle lamp, yet it made a difference of over 2 per cent. in the life efficiency of such lamps, and that since at least 10 million lamps per annum were purchased in the States on life efficiency tests, a difference of 2 per cent. was an appreciable amount, and had commercial consequences. Dr. Glazebrook took the opportunity of expressing his appreciation of the reception accorded to the delegates at St. Louis.

Prof. S. P. THOMPSON, F.R.S., averred that where a widely-used standard was found to differ from the theoretical unit, experience had shown the best plan to be to scrap the unit and retain the standard. The English legal gallon, for example, was not exactly 277·25 nor 277·274 cubic inches, nor was it exactly the volume of 10lb. of water, but simply a particular pot kept at the Board of Trade. He strongly advocated that we should retain the standard ohm legalised by the Order in Council, irrespective of any difference that might be found to exist between such ohm and the ideal definition. Prof. Thompson then pointed out that it was absolutely unnecessary to adopt, as primary standards, more than one electrical unit—the ohm—because, since the metric system is legal, the watt, which is $10^7$ ergs per second, is a definite quantity of power which cannot be altered, and is 1-746 of one horse-power (at London). Consequently, as the volt was equal to $\sqrt{\text{watt} \times \text{ohm}}$ and the ampere to $\sqrt{\text{watt} \div \text{ohm}}$, there was no need to define further either volt or ampere, if watt and ohm were both legal measures. Prof. Thompson then eulogised Georgi's system of units, of which an admirable exposition had been given by Signor Ascoli at St. Louis, and which eliminated the $4\pi$ difficulty.

Colonel CROMPTON stated that he had worked for years to secure a system of two standards instead of three, contending that this would better suit practical engineers. He favoured the E.M.F. and the resistance as the standards. It did not concern the manufacturer whether the standards were exactly correct, except that it would prevent him from accurate approximation to the mechanical standards. We must, therefore, be content with the watt and the ohm.

Mr. H. E. HARRISON, while agreeing with Prof. Thompson regarding the selection of standards, could not concur with him in regard to the $4\pi$ difficulty. If we altered our magnetic units, this factor still remained. It might be dealt with either algebraically or geometrically, but it could not be eliminated. Prof. Perry had stated that a hundred years hence people would wonder why we did not get rid of $4\pi$ long ago. He (the speaker) thought that in a hundred years' time people would regard Prof. Perry's view in much the same light as we look upon the attempts a hundred years ago to square the circle. What Prof. Ayrton had stated about the ohm emphasised the fact that we should have units which should be our ideal, and that our standards should be as far as possible in accordance with the units, and we should always be trying to make our standards more accurate. He thought that it would be a distinctly retrograde step if we adopted our standards as our units. Quoting Dr. Webster's remark at St. Louis, that the standards of the different countries differed by probably less than one part in 1,000, he expressed entire concurrence with him that such a margin was commercially negligible.

Mr. C. W. S. CRAWLEY said that it did not signify one iota whether standards were 1 per cent. out from the theoretical units, as errors could be allowed for. Prof. Thompson stated that we only needed the ohm, but this implied an absolute determination of the watt, which came to very much the same thing as determining the volt or the ampere, while from the users' point of view the ampere and the volt were wanted as absolute standards to be passed round the country for regular practical work. He predicted that in 10 years' time a practical man would not look at the mercury ohm. He concluded by recommending that we should adhere to our standards as they were "for ever and ever, Amen!"

At the suggestion of the PRESIDENT, a hearty vote of thanks was accorded to Mr. Duddell.

---

**The following list of Council nominations for election of Council and hon. officers for 1905-6 was announced at the general meeting held last week:**

*President.*—Mr. John Gavey, C.B.*

*Vice-Presidents.*—Dr. R. T. Glazebrook, F.R.S.;* Mr. J. E. Kingsbury;* Mr. W. H. Patchell; Mr. W. M. Mordey.

*Members of Council.*—Mr. T. O. Callender; Mr. W. A. Chamen;* Mr. W. Duddell;* Colonel H. C. L. Holden, R.A., F.R.S.;* Mr. S. Z. de Ferranti; Mr. F. Gill; Mr. F. E. Gripper; Mr. J. S. Highfield; Mr. H. Hirst; Mr. Walter Judd;* Mr. Gisbert Kapp;* Mr. C. H. Merz; Mr. C. P. Sparks; Mr. G. Marconi; Mr. C. H. Wordingham.*

*Associate Members of Council.*—Mr. Albert Campbell;* Mr. T. Mather, F.R.S.; Mr. A. J. Walter.

*Honorary Auditors.*—Mr. F. C. Danvers; Mr. Sidney Sharp.

*Honorary Treasurer.*—Mr. Robert Hammond.

*Honorary Solicitors.*—Messrs. Wilson, Bristows, and Carpmael.

The names marked with an asterisk are those of gentlemen nominated to fill the vacancies in the Council in accordance with Article 45 of the articles of association. All the honorary officers being eligible are nominated for re-election.

---

## A HIGHLAND LAMENT.

BY SIMPLEX.

Oh waesome oor that saw the birrth
  Of turbine thochts in Pairson's heid!
I weesh that I wes aff the airth
  Or else the turbine men wes deid.

I'm a receeprocatin' mon,
  I luve tae hear the bearin's boomp.
I coont the piston's put upon
  That's relegated tae a poomp.

This whirrligiging thing I hate,
  For whatna gude is it ta dae?
Tae see the fearsome thing gyrate
  Gars ma puir stommick gang agley

I widna greet gin it hed ocht
  Tae need a feetter's tender haund,
But it hes rin sin' it was bocht,—
  I haena had tae slack a glaund

I've hed enouch! I winna bide
  Tae watch a high-speed coffee-mill
I'll droon me in ma native Clyde
  An' bid ma weary hert be still.

## POWER v. LIGHT.

The paper on "Stand-by Charges and Motor Load Development" read by Mr. A. M. Taylor before the Birmingham Local Section in December last, was discussed last night before the parent Institution. It raised again the important question which every station engineer is interested in, of how the electrical plant in central stations can be used to the fullest extent. Indirectly, it also shows how large the diversity factor is in the qualifications of a successful central-station engineer. The first essential is without doubt that the man chosen to control an electricity supply undertaking should be a thorough engineer with a practical training in the construction of electrical machinery. Combined with this he needs the experience of a marine engineer in the running of steam-engines and maintenance of boilers. His undertaking will not be successful unless he is a good organiser of labour, and capable of getting the best output from each member of the staff. After these qualifications he needs to have a critical mind in the dissection of accounts, in order that he may, as Mr. Taylor has done, predetermine the cost of production and the price which must be charged to make the undertaking successful commercially. After all this he needs the power to convince his committee that his estimated figures are correct, and the tact of a diplomat to persuade a great variety of consumers that his proposals are fair to all concerned. The return for these qualifications is not superabundant, but we are proud to think that the central-station engineers of this country are second to none in the care with which they discharge their onerous duties. Coming now to the subject of Mr. Taylor's paper, it must be borne in mind that practically all the electrical undertakings in this country were started with the object of supplying electrical energy for lighting purposes. We naturally do not include amongst these those power distribution companies which during the last few years have commenced to give a supply in bulk to large consumers over considerable areas. The fact that the lighting load makes an exceedingly poor use of the machinery required to meet the demand in mid-winter, has led to numerous suggestions and many practical schemes for the improvement of the load factor. It was the Brighton Corporation, under the advice of Mr. Arthur Wright, that took the lead in this matter by introducing the maximum demand system, which is now so largely employed throughout the country and abroad. With this system no attention is paid to the time at which the maximum load of any consumer occurs when fixing the price which he has to pay for his electrical energy. Hence, although it very greatly reduced the cost of light or power to the long-hour consumer, it was not possible to give as low a price for power supply as is the case under the system which Mr. Taylor is supporting. With this the user of power who does not require his motor to be running during the lighting load peak gets special reductions which make it worth his while to reorganise his work to prevent this coincidence. In this matter, again, Brighton has taken a lead, and the Corporation are selling about three-quarters of a million units annually on the "restricted hours'" system. It will be seen from the brief *résumé* of the paper which we reproduce in this issue that to these "restricted hours'" consumers no charge is proposed for interest and sinking fund on the capital outlay. This is on the ground that the plant used would have in any case to be placed in the stations to meet the lighting load. In consequence of this the whole of these charges are to be paid for by the consumer using electric light, and the power consumer gets specially favourable terms. We think this is not unreasonable in view of the fact that

Digitized by Google

the restricted hours' consumer is debarred during the winter from using his motor after, for instance, 3.30 p.m. in November, 3 p.m. in December, etc. This makes it impossible for a considerable number of power users to adopt the system, and these then have to bear a fair share of the capital charges on the generating plant. The system in question is by no means a new one on paper, and it has been used extensively both at Brighton and in Montreal. In this last instance the ordinary charge per horse-power per hour is 1·6d., whereas the consumers who agree to the limited hour supply are only charged 1·24d. That this concession is appreciated is shown by the fact that some 30 per cent. of the total number of motors connected to the mains come under the cheaper rate. This percentage is on a total demand of 31,000 h.p. We heartily endorse Mr. Taylor's advocacy of the system, and his figures and curves for determining actual stand-by costs form a valuable addition to the literature on the subject. At the same time we do not think his proposal to instal isolated batteries on a consumer's premises to meet his demand during the peak load should be undertaken by the municipalities. It is obviously open to any consumer to instal such a plant as will enable him to get the cheapest supply of electricity with the alternative systems of charging in vogue. The upkeep of this additional plant of a large number of sets of small accumulators scattered throughout the town should not be undertaken by a municipal body. The conclusion of the whole matter is that there is a very large field for the supply of power in nearly every town which can be developed rapidly if the prices are reduced, as they can be. It remains for the engineer in each town to convince his committee, where he has not already done so, that these low prices are commercially feasible. He will then have to meet the complaints of small lighting consumers and of the gas industry that he is selling under cost price and showing favour. These charges can best be answered by satisfactory balance-sheets.

## FORTHCOMING EVENTS.

FRIDAY, MAY 5.

**Junior Institution of Engineers.**—At 7 p.m., "The Influence of Depth of Water on Speed of Vessels," by Mr. Leslie C. Lambert; and "Condensing Plant," by Mr. James N. Boot.

SATURDAY, MAY 6.

**Electrical Engineers' Corps (R.E.V.).**—At 8 p.m., Bohemian concert at the Caxton Hall.

MONDAY, MAY 8.

**Institution of Mechanical Engineers (Graduates' Section).**—"Design and Construction of Horizontal Engines," by Mr. A. B. Scorer.

TUESDAY, MAY 9.

**Institution of Electrical Engineers (Glasgow Section).**—At 8 p.m., "A.C. Motors in Industrial Service," by Mr. P. D. Ionides.

THURSDAY, MAY 11.

**Institution of Electrical Engineers.**—At 8 p.m., "Telephone Traffic," by Mr. H. Laws Webb.

**Iron and Steel Institute.**—At 10.30 a.m., at Institution of Civil Engineers, annual meeting.

FRIDAY, MAY 12.

**Iron and Steel Institute.**—At 10.30 a.m., annual meeting continued; at 7 p.m., annual dinner at Hotel Cecil.

**Physical Society.**—At 8 p.m., "A Simple Method of Determining the Radiation Constant, suitable for a Laboratory Experiment," by Dr. A. D. Denning; "A Bolometer for the Absolute Measurement of Radiation," by Prof. H. L. Callendar; and "The Resistance of a Conductor the Measure of the Current Flowing through it," by Mr. W. A. Price.

SATURDAY, MAY 13.

**Birmingham Electric Club.**—At 7.30 p.m., "Cheap Electrical Energy for Power Purposes," by Mr. J. A. Jeckell (provisional).

**Junior Institution of Engineers.**—Visit to Dorking water, gas, and electricity works.

---

**Rugby Engineering Society.**—May 20, visit to the Lots-road power station at Chelsea.

**Incorporated Municipal Electrical Association.**—June 27-30, annual convention.

## ON THE SELLING OF SPECIFICATIONS.

*(With Apologies to Mr. Dooley.)*

"Well, sir," said Mr. Dooley, "th' Free Traders say that if we ain't fitted f'r an industry we should let th' Dutchmen take it, an' thin we can make a livin' be buyin' th' things fr'm thim. But I don't believe it; we couldn't. If I couldn't make this bar pay, begob, divvle-a-bit would I let Schwartzmeister come into possession, an' thin hang around th' bar meself drinkin' his pisen, like you're always doin' here, Hinnissy. (Mr. Hennessy started.) I'd sell him sausages or tillyphones, an' say I made thim in me wur-ruks at Ballymarroo, even if I didn't. That's why I like th' way th' architec's have ——"

"Phwat's that?" asked Mr. Hennessy.

Mr. Dooley raised his eyebrows. "An architec'," he said, "is a man who knaws a lot about fees an' nawthin' about th' elictric. Whin he is busy he's countin' th' number iv bricks in th' drawin' iv a house, an' charging a guinea a piece f'r his trouble. Whin times is slack he's a sort iv insultin' ingineer, but iv coorse he can't live be that alone. He's got to knaw 'how to git on.' So he publishes spicificayshuns an' sells thim. In th' past, whin a conthractor wanted a job, he jest wint to th' nearest insultin' ingineer an' asked f'r a spicificayshun. 'I'm sorry,' says th' insultin' ingineer, 'but I'm out iv spicificayshuns to-day, owin' to th' failure iv th' blarney crop,' he says. 'But if ye'll call in again nixt month, maybe ye can have, wan or two if ye'll jest lave your goold watch or umbrella,' he says, 'as a pledge iv your boney-fidees.'

"You see, Hinnissy, some conthractors may be honest, but insultin' ingineers is quite right to protect thimsilves fr'm handin' th' sweat iv their brows to men who may, f'r all ye knaw, be sleepin' on th' Embankment at nights. If th' electric trams was there, they might be able to get home to th' County Council dwellin's be sellin' a box or two iv ma-atches.'

"But all that's altered now. Th' architec' is diff'rent fr'm th' real insultin' ingineer. He is used to deal wid Ganderbilks an' Waldorf Asthors an' Bentley-Martins. He's much too keerful f'r to hand the sweat iv other people's brows in exchange f'r goold watches or umbrellas, which may have been lifted in th' House iv Commons or at th' Duchess iv Belgraviah's ball. Th' architec' ain't goin' to run th' risk iv bein' becked f'r rayceivin' stolen property. If he parts wid a spicificayshun, it's f'r hard cash down, an' he never gives discount, although I might be wrong in sayin' he wouldn't take any. He's not givin' away nawthin' free. That's phwat I call th' right sort iv Free Trade. Why, th' counthry that can projooce men wid noshuns like that f'r raisin' th' wind deserves to prosper. Think iv it, Jawn, how th' simple, foolish insultin' ingineers have been givin' back th' deposits f'r years, an' losin' a honest means iv keepin' a motorcar, begob. Suddinly th' architec', who knaws more points about gettin' fees than a lawyer, comes along an' advertises: 'Spicificayshun f'r th' lightin' be elictric iv th' Pig an' Beetle public-house will be sent on rayceipt iv ten guineas, which will not be rayturned.' Whin he comes down nixt mornin', th' post orfice vans are blockin' th' whole street, an' th' architec's fortune is made be a stroke iv masterly genius, as Hogan says.

"You can get a spicificayshun any day fr'm a common insultin' ingineer. But if you knaw you're goin' to get your money back, you can bet your last cent, Hinnissy, that he don't think much iv the spicificayshun himself. But it's different whin an architec' offers f'r to sell his spicificayshun f'r ten guineas. You can tell that he thinks a lot iv it, an' besides, you an' me an' everyone else would pawn all th' masses f'r our souls to get an elictric spicificayshun be an architec'.

"I see be th' pa-apers that William I. is rayturnin' he' th' Siberian Railway fr'm Tangier to th' Salt-iv th'-Earth; an' if I'm not mistaken he's got wind iv th' fur-rust new industry started in this free counthry f'r th' last 50 years. Mark my wur-ruds, Jawn, they'll be dumpin' spicificayshuns into Dover befure th' month is out; an' thin you'll see Joe Chamberlain introjoocin' a depootayshun iv architec's to th' Prime Minister."

"Well, well," said Mr. Hennessy, "it's a pity to see good wur-ruk spoiled, avick."

Digitized by Google

"True f'r ye," replied Mr. Dooley, "but ye may be assoomin' too much."

## THE MARCONI-DE FOREST LITIGATION IN THE UNITED STATES.

In our issue for April 14, on p 521, we referred to a decision given in the United States Circuit Court on the above case, which is the first in which wireless telegraph patents have been fought. We now reproduce from the columns of the *Electrical World and Engineer* of New York the following fuller extracts from the judgment:

On April 11 Judge Townsend handed down an opinion in a suit involving the validity of the reissue of the fundamental Marconi patent. The original patent was issued July 13, 1897, and the reissued patent is dated June 4, 1901. The defendant in the suit was the De Forest Wireless Telegraph Company, the complainant being the Marconi Wireless Telegraph Company of America. The opinion is unusually long and discusses almost every phase of the art of wireless telegraphy. Of the 56 claims in the Marconi patent, those in contention were claims 1, 3, 5, 8, 10, and 24. The first part of the opinion discusses the general principles of wireless telegraphy, quotations being given at length from the descriptions in the patents of Marconi and De Forest. It was held that the material differences between the De Forest system and that of the Marconi patents, barring the question relating to elevated conductors, are found in the different construction and operation of the receiving devices, and these two devices are then described in detail.

The main point of the decision relates to the receiving conductor, and in this connection there is considered the work in wireless transmission of Dolbear, Edison, and Kitsee and the publications of Crookes, Lodge, and Popoff. The general conclusion is that if the patent is examined in the light of the facts brought forth in this examination, every element of the claims now in suit is taken from the prior art. The "signalling" and "receiving" instruments are common to the various apparatus from Dolbear, in 1882, to Popoff, in 1895; the Morse key is specifically referred to by Dolbear, Edison, and Kitsee, and is suggested by Lodge; the spark-gap, invented by Hertz, for producing the Hertzian oscillations, is found in Lodge and Popoff; the 1891 Branly coherer, an imperfect electrical contact comprising a tube of filings, and its operation by means of a tapper, are elaborately explained in Lodge's lecture and utilised by Popoff in his experiments, and choking coils are illustrated and described by Popoff. The insulated conductors described and shown as comprising elevated plates suspended on wires were shown in Dolbear, Edison, and Kitsee.

As to the argument of the counsel for the defendant that the said prior disclosures and the imperfect operation of Marconi's apparatus prior to 1898 or 1899, when he introduced various improvements, deprived the original patent of all claim of novelty except for specific improvement on various parts of prior existing complete systems, the Court held that this contention is not well founded, and that the facts stated serve to support the claim for Marconi of a high exercise of inventive ability. No prior existing system was complete, or had been shown or conceived to be commercially operative. A sufficient answer to the attempts to belittle Marconi's great invention, is that with the whole scientific world awakened by the disclosures of Hertz in 1887 to the new and undeveloped possibilities of electric waves, nine years elapsed without a single practical or commercially successful result, and that Marconi was the first to describe and the first to achieve the transmission of defined intelligible signals by means of the Hertzian waves. The exact contribution of Marconi to the art of spark telegraphy may be stated as follows: Maxwell and Crookes promulgated the theory of electrical oscillations by means of a disruptive discharge; Hertz produced these oscillations and described their characteristics; Lodge and Popoff devised apparatus limited to lecture or local experiments or to some impracticable purposes as the observation of thunderstorms. Marconi discovered the possibility of making these disclosures available by transforming these oscillations into definite signals and, availing himself of the means then at hand, combined the abandoned and laboratory apparatus, and by successive experiments reorganised and adapted and developing them into a complete system capable of commercially utilising his discovery. If a later inventor, by the exercise of a discriminating faculty, detects and distinguishes the difficulties, and estimates their proportions and breaks down the barrier, or bridges the interval, or stretches beyond the limitation, by an instrumentality which, in the very facts of its construction and operation, and by the adaptation of its mechanism to the end sought, suggests original and creative design, then, by his contribution of the essential idea in tangible shape, he has invented a new instrumentality, and his monopoly should be sustained.

A considerable portion of the opinion is devoted to the discussion of insulated conductors, this term applying to the aerial wire. The Court held that the weight of argument seems to favour the contention of the complainant that the insulation intended by the patentee was the insulation at the top—the effect of insulation to prevent the oscillations from passing off without operating the transmitting and receiving devices. In the case at bar the functions of the two devices are identical. The original way of transforming the function in Marconi was substantially that of the later way, which is that employed by the defendant. The difference in insulation was not a different way of performance, but an enlargement of scope and increase in the distance of transmission by a greater use of the property of the earth as capacity by means of a continuous physical connection. The Marconi conductors should not be limited to the metallic plates at the top of the vertical wires, but should be construed to cover the wires alone. But whatever interpretation of the term "insulated" be adopted, the decision of the question of infringement rests upon the fact that the Marconi invention in suit is a primary invention, and as such is entitled to a broader range of equivalents, so as to prevent the appropriation of the substance of the invention by a mere change in force accomplishing a mere change in degree

Discussing the Marconi and De Forest receiving devices, it is stated that the defendant's liquid circuit closer or detector could not be used in the Marconi system, being a newly-discovered combination in a newly-evolved class of detectors and covered by its patents. While the defendant's detector is not the equivalent of the "tube containing metallic powder" of claims 8 and 10, it is equivalent of the imperfect electrical contact of claims 1, 3, and 5, because it utilises means identical in function and substantially identical in method with those first employed by Marconi in his primary invention. As to claim 24, covering a tuned conductor, there is no evidence that the defendant uses any tuned conductor, and therefore he does not infringe this claim.

As to claim 1 of the Marconi patent, this is stated to be a new broad claim introduced into the reissued patent which in terms covers every imperfect form of contact in every possible kind of system for producing signals by means of Hertzian oscillations. In view of the limitations imposed upon the Marconi coherer by the disclosures of Branly, Popoff, and Lodge, such a generic claim, much broader than those for the original patent for which it seems to have been substituted, should not be permitted when the effect would be to enlarge the scope of the original invention. In the original patent Marconi limited most of his claim to a combination in the receiver for electrical oscillations, of his coherer, consisting of a tube and powder and means for shaking the powder. But inasmuch as this had been disclosed by prior publications, he applied for the reissue, and now by claim 1 has attempted to cover not merely the coherer of his former claims, or any such coherer in a receiver, or a coherer with means for shaking the powder therein, but every form of imperfect contact device previously disclosed by others, or which might thereafter be discovered, whenever combined with any electrical apparatus using Hertzian oscillations. This claim, if allowed, will apparently cover the prior devices of Lodge and Popoff, the latter of which is a claim to have necessitated the disclaimer and reissue.

Digitized by Google

The Court ordered a decree entered dismissing the bill as to claims 1, 8, 10, and 24, and for an injunction and accounting as to claims 3 and 5, the complainant to recover one-half of its costs.

Both the parties to this litigation claim to have secured advantages from the same. The two claims, Nos. 3 and 5, which the Court declared to be valid, and to have been infringed by the De Forest Company, were given in our issue for April 14. For convenience of reference we reproduce them again here:

"3. The combination, in an apparatus for communicating electrical signals, of a spark producer at the transmitting station, an earth connection to one end of the spark producer, an insulated conductor connected to the other end, an imperfect electrical contact at the receiving station, an earth connection to one end of the contact, an insulated conductor connected to the other end, and a circuit through the contact, substantially as and for the purpose described.

"5. The combination, in an apparatus for communicating electrical signals, of a spark producer at the transmitting station, an earth connection to one end of the spark producer, an insulated conductor connected to the other end, an imperfect electrical contact at the receiving station, choking coils connected to each end of the contact, an earth connection to one end of the imperfect contact, an insulated conductor connected to the other end, and a circuit through the coils and contact, substantially as and for the purpose described."

It is claimed by the American Marconi Company that these clauses are quite general enough to cover the use of any form of aerial conductor and grounded connection. On the other hand, the De Forest Company claim a victory because the first claim of the Marconi patent was not sustained. With respect to claims 3 and 5, this company read the decision to mean that any system which does not employ an aerial conductor insulated at the top does not infringe the Marconi patent. Any systems, therefore, which employ other connections to the aerial conductor, and which do not employ an earth connection, are said to be free of infringement. The same company also read the judgment to the effect that other systems which use magnetic detectors or other apparatus for detecting the oscillations which are in imperfect contact type can be freely used. As to the claims declared invalid, Nos. 8 and 10, these were not infringed by the De Forest system, as they were limited to coherers containing metallic powder. The firm also said that claim 24, which was held not to be infringed, was as broad a frame as could possibly be drawn on the Marconi system.

The general impression left on one's mind from the above report of the judgment is that there is opportunity for a good deal more litigation over the wireless telegraph patents. The patents for details which have been issued to various experimenters are numerous, and it will be no easy matter for any company to maintain a complete monoply as far as patent rights are concerned. The commercial side of the question, however, is somewhat simpler as far as this country is concerned, because the Marconi Wireless Telegraph Company have already entered into long-period agreements which give them exclusive rights. For example, they have a contract with Lloyds, under which for 14 years no apparatus except the Marconi can be used to communicate from Lloyds' stations by wireless telegraphy with ships equipped with other than Marconi receiving apparatus. The agreements with the principal shipping companies, and also with the Admiralty and Post Office, are more or less on the same lines, which makes the position extremely difficult for any rival system. This, of course, is the situation in this country only, and in the States the De Forest Company may by their commercial policy be able to secure similar advantages.

## APPOINTMENTS VACANT.

**Borough Electrical Engineer and Tramways Manager**, Southend Town Council. Salary £400 per annum. Applications by May 8. See advertisement in last issue.

**Improver**, Coventry electricity works. Salary £50 per annum. Applications by May 10. See advertisement.

## THE ALTERNATING-CURRENT SERIES MOTOR.*

BY F. CREEDY, STUDENT.

*(Continued from page 593.)*

### Experiments on the Series Motor.

In order to verify the above theory, a series of experiments was undertaken, with the view of showing (*a*) the accuracy of the circle diagram described therein; (*b*) the effect of the number of turns on the field on the performance of the motor, and the fact that there is a certain number of field turns which gives a better power factor than any other; (*c*) the effect of altering the number of turns on the armature; (*d*) the effect of altering the frequency; together with one or two other points of interest in this motor. The motor employed in these experiments was a small bipolar overtype machine, with a double-wound armature having 36 slots and 36 commutator segments. The double winding was intended to improve the commutation (which it did not do), and also to enable one to double the number of armature turns by simply altering the commutator connections. The field magnets were fitted with two coils, having 84 and 104 turns respectively. A connection was tapped off from the middle of the coil having 84 turns, so that 42 turns on the field were also available.

It was found, after some experiment, that the only available way of obtaining a reliable brake test was by using an electric generator as brake. As this machine was not always to be had, it was decided not to take any readings of output while investigating the methods of obtaining good power factor, etc., but to make an independent investigation as to the efficiency afterwards. Accordingly, while observing most of the curves below, readings of current, watts, and speed only were taken, the speed being kept constant in the following way. The pulley was fitted with a brake-strap, which was loaded until approximately the right speed was attained, when the final adjustment of the speed was made by altering the pressure on the brake-strap by hand. In this manner very good circles, such as those shown below, were obtained. A set of experiments was first made in order to show the effect of varying the number of field turns on the power factor, etc. The report of these is shown in Fig. 5.

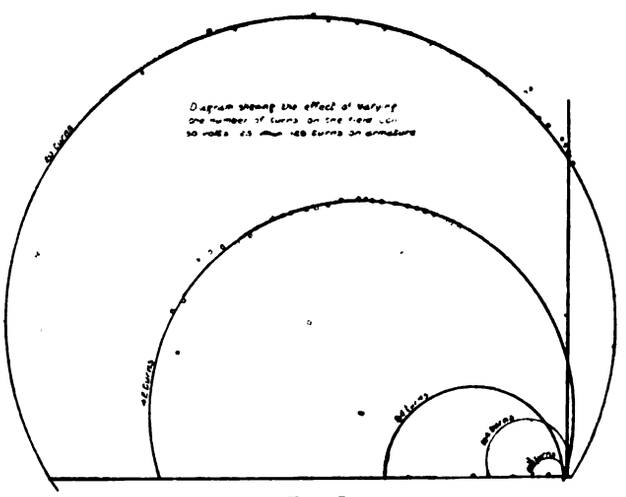

FIG. 5.

These curves were all taken at 25 frequency, and show the *locus* of the current vector as we vary the speed, when we have 188, 104, 84, 42, and 20 turns on the field. The two upper curves were taken at 50 volts, so I have been able to put the points in. The others, however, were taken at a different voltage, so I have been obliged to reduce them to 50 volts before putting them in, and have, therefore, merely indicated the range over which the observations extend. The points, however, lie as closely on the circles as do those shown. The curves show clearly the increase of the power factor, at a given speed, as we decrease the number of turns on the field, and also, of course, the increase in the size of the circle. The range of speed over which the observations extended in all these and the following

* Paper read before the Institution of Electrical Engineers.

Digitized by Google

experiments was from 600 to 3,000 revolutions per minute. The curve corresponding to 20 turns, which shows such excellent power factor, was obtained by putting the two field coils in opposition, there being a difference of 20 turns between them. The high power factor is obtained largely at the expense of efficiency.

In the above set of experiments I was unable to reduce the number of field turns below 20, and thereby increase the current taken by the machine, for fear of burning it out. However, after the number of turns on the armature had been doubled, and the armature impedance thereby quadrupled, some further experiments (see Fig. 6) were

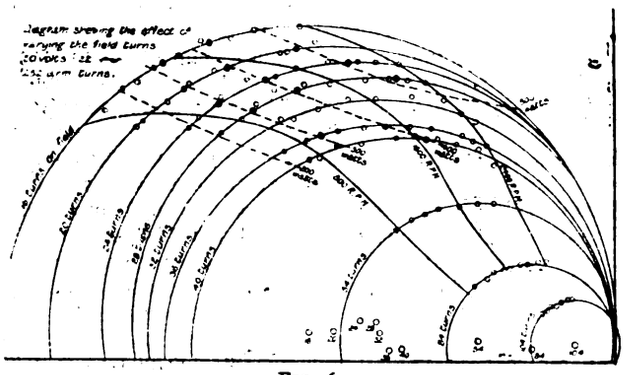

FIG. 6.

made which clearly demonstrate that if we decrease the number of turns below a certain point, the power factor decreases. Thus we have shown experimentally that there is a certain number of turns which gives a maximum power factor, as was shown theoretically above.

In order to verify the construction given in Fig. 2 for the speed, the distance, S P (Fig. 2), is set out in Fig. 7 against the measured speed. This is done in the case of the four circles corresponding to 20, 42, 84, and 104 turns

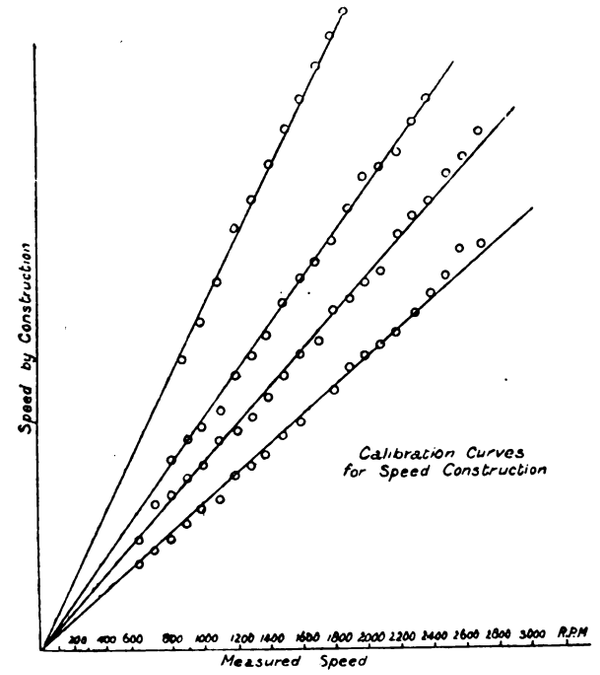

FIG. 7.

respectively. In order to prevent the lines from coinciding, a different scale was taken for S P in each case. From these curves it can be seen how exactly proportional is the line S P to the measured speed. I have no doubt that equally good curves could be obtained from the other circles shown in the paper, but the four given seemed amply sufficient to establish the correctness of the speed construction, so no more were plotted. These curves, together with the large number of experimental circles shown in Figs. 5, 6, 8, and 9, constitute a complete verification of the circle diagram of the series motor, since the fact that the torque is proportional to the square of the current, so long as the magnetic circuit does not approach saturation, is self-evident. From the constructions for torque and speed, and that for the input, which also admits of no doubt, the constructions for output and efficiency follow immediately.

The next series of experiments made was intended to show the effect of varying the frequency on the performance of the motor. The result of these is shown in Fig. 8.

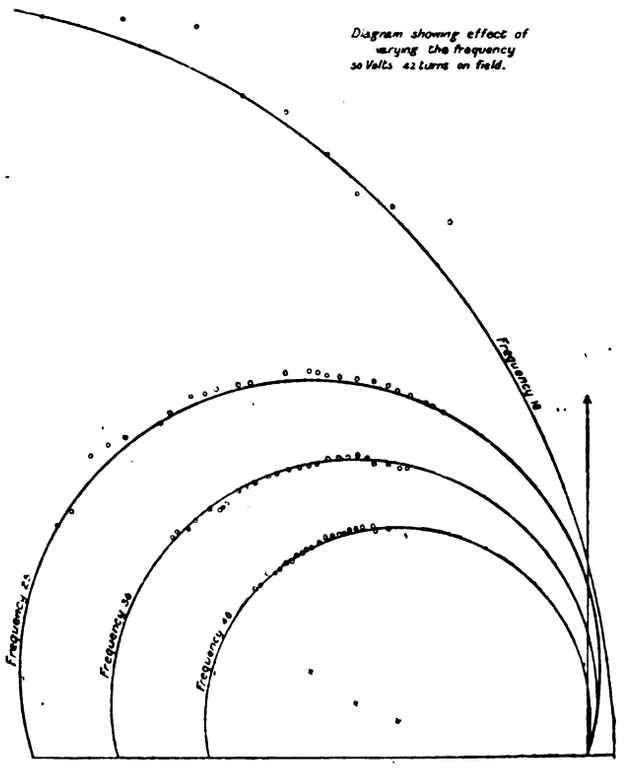

FIG. 8.

The increase of power factor and of the size of the circle with decreasing frequency, which theory leads us to expect, is very well shown. The curves also show that as the frequency gets less, a given change in it produces a greater effect. This, of course, is no more than one would expect. The alteration in both power factor and size of circle, when the frequency is reduced from 25 to 18, is very marked. The curve for 18 frequency was almost the only bad one obtained. It was several times repeated with the same results. The reason why it is so bad, is probably the excessive current taken by the motor.

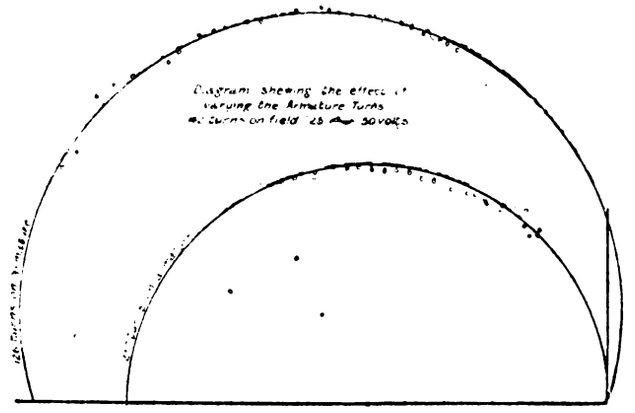

FIG. 9.

In Fig. 9 are given two curves showing the effect of altering the number of turns on the armature.* The improvement in the power factor thereby obtained is clearly shown, and also the decrease in the size of the circle due to the increased armature impedance. In Figs. 10 and 11 are given some curves showing the effect of the number of field turns on the output and efficiency. These were taken simultaneously with those in Fig. 6. Fig. 10 shows three efficiency curves corresponding to 20, 36, and 54 field turns respectively. These show that the efficiency at any given speed rises as the number of field turns increase, thereby agreeing with theory.

* When the number of armature turns is mentioned on the diagrams, the total number of turns is meant, not half this.

Digitized by Google

In Fig. 11 I have plotted the output against the number of field turns for various values of the speed. It will be seen that it appears to rise somewhat rapidly from zero to a maximum, and then to gradually decrease again with increasing number of turns. That the output must have a maximum is obvious, for it is zero where there are no turns on the field, and also when there are a great number. It must consequently have a maximum between these two points. The value of $n$ for which this occurs was worked out mathematically, but the expression for it is so complicated that it seemed useless to give it.

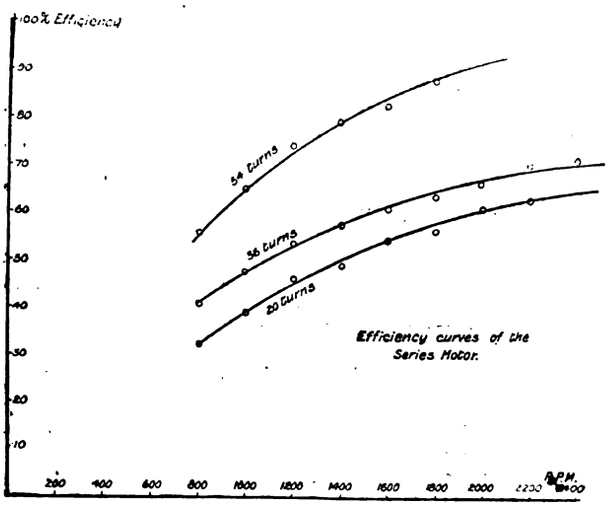

FIG. 10.

In Appendix I. is given a diagram (Fig. 15) showing the various effects of varying the number of field turns in a series motor, while keeping the number of armature turns constant. Although Appendix I. was written after the experiments in Fig. 6 were performed, these latter fortunately enable us to verify this diagram almost completely. In Fig. 6 I have drawn in three lines of constant speed. The similarity in shape between these experimentally determined lines and the theoretical ones in Fig. 15 is very marked. By plotting a series of curves of output against speed, for various numbers of field turns and drawing lines through them corresponding to outputs of 0·2, 0·3, 0·4, and 0·5 kilowatts respectively, I was able to ascertain the points on each circle corresponding to these

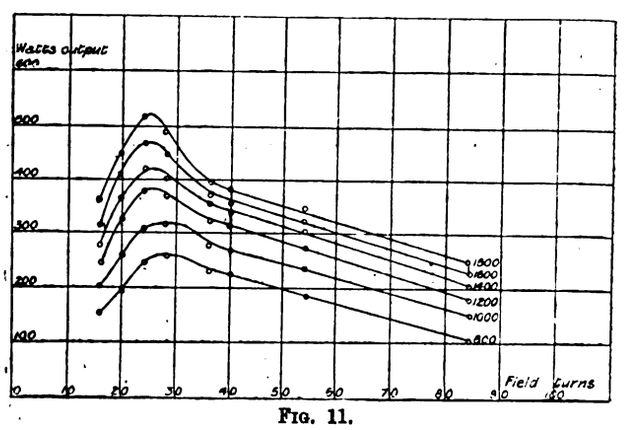

FIG. 11.

outputs. These points are marked in Fig. 6 with a small circle with a cross inside. It may be seen, that if these points do not afford conclusive evidence that the lines of constant output are circles, they at least show that circles, such as are indicated by theory, serve to represent the lines of constant output remarkably well.

(*To be continued.*)

## NOTES ON THE CARE AND MANAGEMENT OF DYNAMOS.

BY W. J. H.

A most important element in the efficiency of dynamos and motors, and one which makes considerable difference to their lifetime, is the care with which they are treated, and the immediate remedy of any fault or irregularity that may appear in them. It requires a certain amount of experience to be able to detect these faults and irregularities as soon as they occur, and also to know the proper steps to be taken to correct them before the damage becomes at all serious or has time to deteriorate the machine. For this purpose, and for the benefit of any readers of the *Electrical Engineer* who may have the care of dynamos and motors, the following notes are written.

In many cases a breakdown or failure in a dynamo may be traced to negligence, or carelessness pure and simple. Dynamo machinery cannot withstand ill-usage and overloading, although motors generally increase their output in proportion to the demand made upon them until a certain limit. If intelligence and commonsense are used, a capable engineer should have no difficulty in looking after an electrical plant, and in keeping it up to its standard of efficiency by a system of regular running, cleanliness, and general care. Of course, the treatment of dynamos in general applies to motors also. A most important point to be noticed is the temperature to which a dynamo attains after a few hours' run; good modern machines rarely increase in temperature more than 40deg. to 45deg. F. above the surrounding temperature of the room in which they are running, after a run of many hours on full load. The parts that are seriously affected by a temperature rise are, of course, the armature and field coils, and any temperature under 130deg. F. is quite harmless to the insulation of these.

Care should be taken that the dynamo is quite rigid on its foundation, and no vibration whatever should be permitted to take place when the dynamo is running. This point should always be kept in mind by the attendant, who should make it his place to tighten up all loose bolts and bearings as soon as any tendency to looseness is apparent. In setting the brushes on the commutator, the points should always be placed diametrically opposite each other, resting very lightly on the commutator. They will probably need moving forward occasionally to maintain this position, and if it is noticed that the points become ragged or rough and uneven, they should be trimmed with a file or scissors.

It is most important that continuous-current machines should be free from sparking at full load. There should be a system of continuous lubrication, and all bearings should run cool. The most satisfactory lubricant to be used for the commutator is vaseline, which should be used sparingly, and wiped carefully off with a non-fibrous rag, in order to leave the least possible amount of lubricant to ensure satisfactory results. If the brushes are made of alloy sheets, lubricating the commutator is not often necessary, as they give excellent results without. It sometimes happens that from inattention, or structural faults, that the surface of the commutator becomes grooved and uneven; the armature should be taken out and turned up lightly in a lathe. With moderate attention the commutator should soon assume a fine dark polish.

When grit or dust gets into the bearings, they should be cleaned by means of thin oil poured into them, which will wash out the dirt. The importance of a perfectly true "run" cannot be over-estimated, and a crooked belt which slides from one side of the pulley to the other is sure to give trouble sooner or later. The joint in a belt should be as smooth and as near the size and shape of the rest of the belt as possible, as the damage done to a dynamo with a belt which "knocks" as it passes over the pulley is incalculable.

In order to run in a satisfactory condition the dynamo should make as little noise as possible. One of the first signs of looseness of bolts or vibration is a loud noise, which means that the dynamo is wearing in some part and needs tightening down, or else it is attributable to loose bearings, or armature or pulley out of balance.

It is frequently the habit of an inexperienced attendant to replace a blown fuse with one of greater capacity, thus inducing overload to the dynamo. Automatic cut-outs are used largely recently, which prevent this occurrence. A dynamo may refuse to start if the contacts be loose or bad, or if a circuit be broken and the residual magnetism be

Digitized by Google

diminished. When a motor fails to start or stops, the cause may be a break in the circuit, bad contact, or loss of magnetism or overload.

When handling a dynamo when working the attendant should always see that his hands are dry, and if anything goes wrong he should preserve his equanimity, and keep cool, as presence of mind can often avert catastrophe.

## INCORPORATED MUNICIPAL ELECTRICAL ASSOCIATION.

The meeting of this association to be held in Edinburgh on June 27 and following days will have under consideration a proposal which should attract a large number of associate members and associates. At present the annual conventions are of little service to the assistant engineers in central stations, as they cannot as a rule be absent from their duties while their chiefs are away. It will be seen from the following circular letter that the council wish to arrange additional meetings for the benefit of assistant engineers provided the scheme receives due support:

PRIVILEGES OF MEMBERSHIP.

Dear Sir,—It is felt that associate members and associates are at some disadvantage as compared with members in regard to attendance at the annual convention, it being impossible for an assistant to be absent at the same time as his chief.

The council being desirous of removing this difficulty and of enlarging the scope of the association, has under consideration a scheme for holding either a second convention, or quarterly provincial meetings each year, specially for those who are at present prevented from attending the annual gathering.

Before, however, coming to any decision in the matter, the council is desirous of ascertaining the opinions of those concerned, and particularly as to what extent they will support it, and therefore asks that the attached form may be filled in and returned to the secretary as soon as possible.

Whether the scheme can be carried to a successful issue or not will depend almost entirely upon what proportion of those now eligible for associate membership or associateship make application to join, in view of the proposed extension of the scope of the association.

The matter is, therefore, practically in the hands of those in whose interests the scheme is promulgated.—Yours faithfully,

(Signed) C. MCARTHUR BUTLER, Secretary, I.M.E.A.
Staple-inn-buildings, Holborn, London, W.C.

The questions on the form are five in number, and the engineers in the various municipal supply stations are also asked for any personal observations or suggestions they may wish to offer. The questions read:

1. Are you in favour of a second annual convention, to be held specially for those unable to attend the first?
2. Should such second convention be held at a fixed centre, say London, or in whatever district the first is held?
3. Would you attend such meetings when possible?
4. As an alternative it is suggested that council meetings be held, say, four times a year in different provincial centres, and on each occasion a day be given to reading of papers by associate members and associates, and visits to works in the district. Would you attend such meetings held in your district, and be prepared to support this suggestion?
5. If not already affiliated with the association, will you join it if provision is made for a second convention or provincial meetings?

It seems to us that an all-important question should also be addressed to the chairmen of electricity committees on the question of the expenses incurred by associate members when attending such a convention or meetings. The expenses for a reasonable proportion of the staff should be borne by the department they serve. The views of the chairmen of committees on this point would influence the answers of the assistant engineers to the above question.

## IRON AND STEEL INSTITUTE.

As previously announced, the annual meeting of the institute will be held, by kind permission, at the Institution of Civil Engineers, Great George-street, Westminster, on Thursday and Friday, May 11 and 12, 1905, commencing each day at 10 30 a.m. The following is the programme of proceedings:

THURSDAY, MAY 11.

10.30 a.m.—General meeting of members. The council will present their report for the year 1904. The hon. treasurer will present the statement of accounts for 1904. Scrutineers will be appointed for the examination of the voting papers. Election of officers and council. The retiring president, Andrew Carnegie, Esq., LL.D., will induct into the chair the president-elect, R. A. Hadfield, Esq. The Bessemer Gold Medal for 1905 will be presented to Prof. J. O. Arnold, Sheffield. The award of the Andrew Carnegie Gold Medal and Research Scholarships for 1905 will be announced. The president will deliver his inaugural address. A selection of papers will be read and discussed.

1.30 p.m.—The meeting will be adjourned.

FRIDAY, MAY 12.

10 30 a.m.—General meeting of the members at the Institution of Civil Engineers. A selection of papers will be read and discussed.

7.0 p.m.—Annual dinner of the institute in the Grand Hall of the Hotel Cecil.

The following is a list of papers that are expected to be submitted:

1. "On Experiments on the Fusibility of Blast-Furnace Slags." By O. Boudouard, D.Sc., Carnegie Research Medallist, 1903 (Paris).
2. "On Recent Developments of the Bertrand-Thiel Process." By J. H. Darby (Brymbo) and G. Hatton (Brierley Hill)
3. "On the Application of Dry-Air Blast to the Manufacture of Iron." By James Gayley (New York). Supplement to paper read on Oct. 26, 1904.
4. "On the Effect Produced by Liquid Air Temperature on the Mechanical and Other Properties of Iron." By R. A. Hadfield, president.
5. "On the Cleaning of Blast-Furnace Gas." By Axel Sahlin (London).
6. "On the Failure of an Iron Plate through Fatigue." By S. A. Houghton (London).
7. "On the Continuous Steelmaking Process in Fixed Open-Hearth Furnaces." By S. Surzycki (Czenstochowa, Poland).
8. "On Accidents due to the Asphyxiation of Blast-Furnace Workmen." By B. H. Thwaite (London).
9. "On the Behaviour of the Sulphur in Coke in the Blast Furnace." By Prof. F. Wüst, Ph.D., and P. Wolff (Aachen).

Reports on research work carried out during the past year will be submitted by C. O. Bannister (London), J. Dixon Brunton (Musselburgh), H. C. H. Carpenter (Teddington), J. C. Gardner (Oldbury), G. Dillner and A. F. Enström (Stockholm), E. G. L. Roberts and E. A. Wraight (London), Frank Rogers (Cambridge), and Walter Rosenhain (Birmingham)—Andrew Carnegie Research Scholars.

Members who intend to take part in the discussions will, on notifying such intention to the secretary, have copies of the papers forwarded to them a week in advance, as far as that may be found possible. Visitors' tickets will also be forwarded upon application.

By the courtesy of the Great Western, the Midland, the Caledonian, the London and North-Western, the Great Northern, the Lancashire and Yorkshire, the Great Central, and other railway companies, special arrangements have been made enabling members attending the meeting to obtain return tickets on payment of a single fare and a quarter on production of a certificate of membership, which may be obtained at the institute offices.

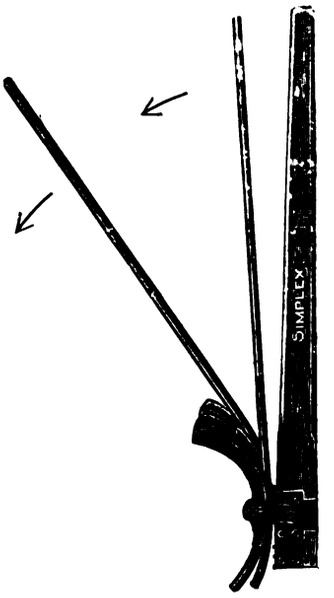
## TRADE NOTICES AND NOVELTIES

### Leakage Indicators.

In view of the new mining regulations, which stipulate that a leakage indicator is to be connected permanently in circuit on the main switchboard, it will, no doubt, interest our readers to know that Messrs. Everett, Edgcumbe, and Co., 87, Victoria-street, Westminster, S.W., have gone very carefully into the question of the best instruments for this purpose, and are now in a position to supply them for all systems, whether direct or alternating current. It need hardly be pointed out that the requirements are somewhat difficult to meet, as it is not only necessary to indicate that a fault has occurred, but also the approximate value of the leakage current, and on which main the leak has taken place. We hope to give a detailed description of these instruments in a later issue.

### Simplex Conduit-Bending Machine.

We illustrate herewith a new conduit-bending machine introduced by the Simplex Steel Conduit Company, Limited, Westinghouse-building, Norfolk-street, Strand, London, W.C.



Simplex Conduit-Bending Machine.

This machine is claimed to be the handiest, most efficient, and cheapest tool for bending tubes on the market. Simplicity and portability are its great advantages, its weight being only 5lb., and there are no loose parts to get lost or out of order. The bender consists of a wooden lever, a hinge link, and a cast bending mould which has two curved grooves of different radii. These grooves together with the corresponding grooves in the end of the lever take conduits up to ¾in. diameter. The method of using the machine is described on a leaflet just issued by the makers.

### High-Tension Apparatus.

The Union Electric Company, Limited, 151, Queen Victoria-street, London, E.C., are about to issue a new edition of their

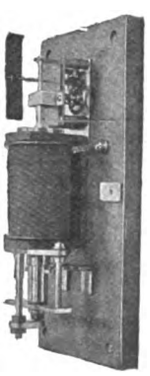


FIG. 1.—Time Relay.

list No. VI. This list (an advance copy of which we have before us) illustrates practically every class of high-tension switchgear for hand and automatic control in both the horn and oil-break types. Some particularly interesting devices for the automatic control of switches are included. The time relay illustrated in Fig. 1 herewith is designed to prevent a momentary short-circuit or overload from opening the high-tension switch immediately. When the time relay has run down in from two to twelve seconds, the release circuit is completed and the switch opened. The device comprises a solenoid acting on an iron core. The movement of this iron core is controlled by a train of wheels connected to an air vane, and when the core has been completely sucked in by the solenoid, the release circuit of the switch is closed. If, however, the circuit through the solenoid is broken owing to the overload not continuing, then the iron core which is connected to the train of wheels through ratchet gear at once falls back to its original position. It is occasionally essential that the time relay shall control the release on ordinary overload, but that on a short-circuit the switch shall be opened immediately; for this purpose the firm supply combined maximum relays, the apparatus consisting of two maximum relays mounted on one insulator. One of these relays is adjusted for slight overload and release through the time relay, the other for heavy overload or short-circuit and immediate release. Fig. 2 illustrates an arrangement of relays for use with the firm's completely automatic oil-break switches to parallel generators or synchronous motors automatically. The great advantage of an apparatus of this description is that it is impossible to parallel otherwise than correctly. By the combination of a pressure relay which fixes the

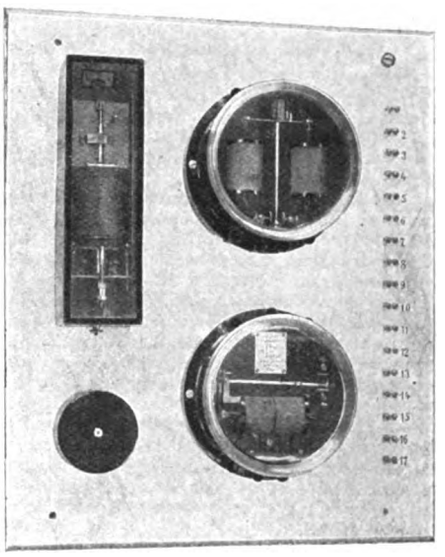

FIG. 2.—Automatic Paralleling Gear.

correct pressure of the incoming machine, a phase relay indicating equality of phase, and a time relay in which the run-off rate (corresponding to the long illumination of the phase lamps) indicates synchronism, the correct moment of synchronism is obtained and the circuit for automatically switching in and out then closed. A small rotary switch is provided for starting the whole apparatus. This is automatically switched out as soon as the main switches have come into action. Only one such gear is necessary, regardless of the number of machines to be dealt with, provided that the pressure transformers and automatic switch-in coils of the respective machines can be connected to it through a four-pole voltmeter change-over switch. The list under notice also includes a large range of high-voltage fuses and some interesting designs in the way of switch pillars and instrument fittings, besides several wiring diagrams and section drawings of standard switchboard designs showing the extreme simplicity of modern high-tension switchgear.

---

WESTRUMITE PATENTS.—We have received an illustrated catalogue of the 1905 improvements in Westrumite patents, giving details of Westrumite No. 1, reliable road preserver, dust layer, and disinfectant; Westrumite No. 2, Westrumite asphalt (new patent of great value), a cheap and easily applied durable asphalt road surface. The manufacturers and sole vendors are Hope and Sons, 22, Billiter-street, London, E.C., with works at Hope's Wharf, Millwall, London, E.; Oak-lane Chemical Works, Limehouse, London, E.; Westrumite Works, West Side, Tilbury Docks, Essex; and at Leicester. Since the actions of "Hope and Sons *v.* Westrumite, Limited," and "Westrumite, Limited, *v.* Hope and Sons" were decided by the Chancery Division of the Supreme Court in favour of Westrumite, Limited, Messrs. Hope and Sons have acquired the right to be manufacturers and sole vendors of Westrumite in the United Kingdom. Instructions for use and details with regard to Pynerzone blocks accompany the catalogue. These blocks contain an extract of Norwegian pine, eucalyptus, and thymol in concentrated form, and are useful for disinfecting roads, manholes, sewers, etc.

# COMPANIES' MEETINGS AND REPORTS.

## CITY OF BIRMINGHAM TRAMWAYS.

The general meeting of this Company was held last week, Mr. Emile Garcke presiding.

The report showed a disposable balance of £60,321, after providing for interest on debentures, dividend on preference shares to Dec. 31, and interim dividend of 5 per cent. on the ordinary shares for the half-year ended June 30, 1904, the net profit being larger by about £3,000 than in the preceding year. The Company carried 54,000,000 of passengers, as against 50 000,000. The balance of £54,000 was proposed to be carried to the reserve fund, which now stands at close upon £300 000. Arrangements have been made for working jointly the various tramways belonging to their Company and to the Birmingham and Midland Tramways Company, the Wolverhampton and District Tramways Company, the Dudley and Stourbridge Electric Traction Company, and the Staffordshire Tramways Company. These companies have agreed to constitute a joint committee, composed of all the directors of the companies concerned. The committee have been working since July 1 last, and for the six months they had been able to effect a reduction in the expenses of about £4,000.

The CHAIRMAN stated that with regard to their relations with the city of Birmingham, an agreement had been effected with the Corporation for the sale of the Company's lines within the district of Balsall Heath, and the Corporation had agreed to purchase the Kyotts Lake depôt. The Company had also consented to the Corporation equipping the horse and steam lines with electric tration during the period of the Company's lease. That was to say, the Company was facilitating the Corporation in their endeavour to electrify the steam lines at the earliest possible date, and, instead of putting the Corporation to the difficulty of waiting until the leases had expired before they were able to enter upon the work of reconstruction, the Company proposed to give them all necessary facilities to enable them to commence the work of reconstruction forthwith. As part of this arrangement the Corporation had given the Company some relief from the heavy charges for permanent way repairs during the remaining part of the lease. One of the greatest difficulties in the way of the Corporation was that the tramways of Birmingham radiated into outside districts whose tramways could not for many years come under the control of the Corporation. In order, therefore, that the public might not be inconvenienced by the changing of cars at the boundaries, the Company and the Corporation were arranging an agreement for mutual running powers. On the subject of motor 'buses the directors were clearly of opinion that the motor omnibuses were not able to compete with electrical or cable tramways, or even with well-designed steam tramways. Motor 'buses, however, were probably preferrable to animal traction, but were not yet sufficiently perfected to enable the directors to say that the whole of their horse omnibuses could be superseded by motor omnibuses. The heavy cost of repair to motor omnibuses and the need for very frequent adjustment of machinery rendered the maintenance of a large service very uncertain; but experiments were being made in view of possibilities.

The report was adopted.

Replying to questions, the CHAIRMAN reminded the audience that only some of the leases expired in 1906, and the leases of the cable line and electric line in Bristol-road continued till 1911. In addition, the Company owned several lines outside the city, consequently there was no question of the Company expiring. A large part of their income would disappear, but the cable and the Bristol-road electric line were practically their best lines, so that their position would not be very seriously modified in 1906. Speaking generally, the directors hoped and believed that the whole of the capital of the Company would become liquid, either by reason of the realisation of properties which would not be required after the leases had expired or by the accumulation of surplus profits. Both these factors would, in the course of time, the directors hoped, make up the capital of the Company.

## PRIMITIVA GAS AND ELECTRIC.

The annual general meeting of the Primitiva Gas and Electric Lighting Company of Buenos Ayres, Limited, was held last week, Mr. H. E. Jones presiding.

In moving the adoption of the report and accounts, the CHAIRMAN said that the results of the past year's working had enabled the directors to recommend a dividend on the ordinary shares of 6 per cent. per annum, an increase of 1 per cent. on the previous year's dividend. The increase of 4½ per cent. in the sales of the Company's gas during the year might not appear to be very large, but it was a fair increase when compared with the results of other gas companies, which generally showed very small increases. This was due to the great saving effected in the consumption of gas by the introduction of the Welsbach burners and mantles. There was, however, a considerable demand for gas cookers and stoves, and in this direction they looked to the present prosperity of the Company being maintained in the future.

The report and accounts were unanimously adopted.

## WEST COAST OF AMERICA TELEGRAPH.

Sir JOHN DENISON-PENDER, presiding at the meeting of the West Coast of America Telegraph Company on Tuesday, stated the increase of receipts from £35,707 to £42,337 was largely due to the introduction of recorder instruments in the place of mirror instruments. The transfer had cost £1,111, and he expected they would have to spend another £200 before that expenditure was completed. Wages had increased £390, and the enlarging of the buildings at Iquique had cost £260. Maintenance of cable and land lines represented £9,203, as compared with £12,155 in 1903. Interest on debts was £6,000, and on income bonds £800, leaving a balance of £7,419. The total at the disposal of the directors was £8,516, which would be disposed of as follows: £6,000 would be placed to reserve (making that fund £10,185), £1,750 to ship reserve (bringing that fund up to £4,000), and £766 would be carried to next year's account.

The report was carried.

## BATH ELECTRIC TRAMS.

The second ordinary general meeting of this Company was held on the 26th ult., Sir Vincent Caillard presiding. Particulars of the report appeared in our last week's issue.

The CHAIRMAN, in moving its adoption, reviewed the progress of the undertaking, and predicted a good result from the Midland Bridge route, now in course of construction, and the Newton St. Loe extension, which has been sanctioned by the Board of Trade. A system of motor 'buses is to be adopted to provide feeders for the trams.

The report was carried unanimously, and Mr. A. A. Campbell Swinton, the retiring director, re-elected.

## RAND CENTRAL ELECTRIC WORKS.

The annual meeting of this Company was held at Winchester House last week, Sir C. Rivers Wilson presiding. Particulars of the report appeared in our last week's issue.

The CHAIRMAN stated that a great scheme was in progress for the formation of a supply of water on the Rand, and when this was carried into force they would be able to obtain their water much cheaper than at present. In view of mining activity on the Rand, and the increasing opportunities of the supply by the Company of electric energy, the prospects were very encouraging, and the directors had great confidence in the future.

The report was adopted.

## BROCKIE-PELL ARC LAMP.

The report for 1904 stated that the sum of £496 had been written off for depreciation of plant, machinery, and tools, and a further amount of £148 expended on new patterns during the year has been charged to revenue account. This left a debit balance of £1,864 on profit and loss account, as against the £2,023 shown in the last account for the 18 months ended Dec. 31, 1903. Despite this result, chiefly attributable to the continued depression of trade and competition, the directors considered that the Company's business is now in a much more promising condition than it was at this time last year.

At the fifth ordinary general meeting held on Tuesday, Mr. H. W. MAYNARD, who presided, first explained the position as regards the directorate. Sir F. Dixon-Hartland and Lord Suffield retired, and Mr. W. Nicolson and Mr. R. Warner succeeded them, but the former gentleman recently died. With regard to the manufacturing work of the Company, he thought there was no doubt that they had been led into taking up one or two lamps that did not come up to anticipations. A considerable change had to be made in them, and that change had been brought about by Mr. Brockie, who had produced the B.E. lamp, on which he (the chairman) did not hesitate to say the future prosperity of the Company largely depended. One firm had ten times repeated their original order for that particular lamp, which had earned golden opinions for its economic qualities. He had been asked whether the directors had any fear of the flame lamp, and he would like to mention that Mr. Brockie had in his mind a flame lamp which he (the chairman) thought would equal anything on the market. Good results were also expected from the Twin lamp. They had good travellers in London, and excellent agencies in Birmingham, Manchester, Newcastle, and Dublin, but it was desirable to spend more money on advertising as soon as finances permitted. The sales of the past year showed a larger number of orders, and something like 4 per cent. higher gross profits than the previous year. Great efforts are being made to dispose of the Company's heavily-rented premises, and with the new lamps, the increasing business in London and in the arc trade generally, with the price at which the Company can manufacture lamps, and with strong hopes of an increase of trade, he was confident of the future and anticipated a very different state of things after another year's working.

The report was adopted.

## BRUSH ELECTRICAL ENGINEERING.

The report for 1904 shows a gross profit of £71,280. General charges, maintenance, interest on debenture stock, and £6,500 carried to depreciation reserve fund absorb £43,200, leaving a balance of net profit of £28 080. The directors recommend a dividend at the rate of 6 per cent. per annum on preference shares for the year, placing £7,000 to general reserve fund, and carrying £3,080 forward. The depreciation reserve fund will then stand at £45,107 and the general reserve fund at £16,450. The sum of £11,508 has been expended on additions to plant and buildings during the year. A considerable proportion of this amount is in respect of a complete plant for rendering wood non-inflammable or fire-resisting, for which a considerable demand has arisen for rolling-stock and other purposes. The Company is engaged upon an important electric supply and tramways undertaking at Bombay, on which the sum of £67,791 had been expended at the end of the year, principally upon account of the construction of the electric supply works. Arrangements are in progress, which it is expected will shortly be completed, for the formation of a separate company to deal with this undertaking, which will secure for the Company important contracts. The general reserve account has been reduced by £11,050, representing the book value of

Digitized by Google

the stock of Universal engines. It is proposed, on the other hand, that the sum of £7,000 shall be added out of profits. The Universal engines have not been satisfactory in some sizes, and, their manufacture having been entirely discontinued, the directors have thought it prudent to write off in full the book value of those remaining on hand. The output from the works shows a considerable increase over that for the previous year, and the volume of orders is well maintained. Competition, however, continues to be severe, and the net profits have consequently not increased in proportion to the turnover. Marked progress has been made during the year at Falcon Works in developing new manufactures and in improving existing designs. This work has involved considerable expenditure on drawings, patterns, experiments, etc., the whole of which has been charged against revenue. The demand which has arisen for motor omnibuses has for some time past engaged the attention of the directors. The Company has already built examples of these vehicles, and arrangements are now being made whereby the interests of the Company will receive suitable attention in connection with this important development.

## AUCKLAND ELECTRIC TRAMWAYS.

The seventh ordinary general meeting of this Company was held on Monday, Mr. C. G. Tegetmeier presiding. Particulars of the report appeared in our last week's issue.

The CHAIRMAN announced that the traffic receipts for the first three months of the current year were £3,000 in excess of the receipts for the corresponding period of last year, and the directors were justified in anticipating that at the end of the 12 months they would have a still more satisfactory report to present than they had now the pleasure of laying before the shareholders.

The report was adopted.

## ORIENTAL TELEPHONE AND ELECTRIC.

The eleventh ordinary general meeting of this Company was held at the Great Eastern Hotel, Sir A. Colvin presiding.

The CHAIRMAN stated that the work of underground cabling at several of the stations was proceeding, and that the expenditure would probably necessitate a fresh issue, for which the shareholders would have the first opportunity of subscribing. The Telephone Company of Egypt, in which this Company is largely interested, continues to make good progress.

The report was unanimously adopted.

## NEW COMPANIES REGISTERED.

**British Electrical Device Company, Limited.**—Capital, £500. Object: to carry on the business of manufacturers of and dealers in electric, hydraulic, pneumatic, and steam engines, dynamos, switchboards, switches, pumps, motors; boilers, batteries, cables, wires, telegraph or telephone instruments, etc.

**Gobron Brillie British Motor Company, Limited.** Capital, £30,000. Object: to acquire the business of a manufacturer of and dealer in motorcars carried on by J. Stenbury, to adopt an agreement with the Share and Finance Contract Company, Limited, and to carry on the business of manufacturers and sellers of motorcars, carriages, and other vehicles.

**Barbados Light Railway, Limited.** Capital, £20,000. Object: to acquire the whole or part of the railways, properties, and undertakings now or lately belonging to the Bridgetown and St. Andrew's Railway, Limited, power being taken, in particular, to acquire the benefit of an option or contract of purchase vested in C. J. P. Cave or G. F. Burn referring thereto, and to carry on the business of light railway owners, suppliers of electricity for power or otherwise, rolling-stock manufacturers, builders, contractors, carriers, etc. Registered office: 9, Great George-street, Westminster.

**National Electrical Manufacturers' Association (Incorporated).**—With 500 members, each liable for not more than £1 in the event of winding up. Object: to take over the property of the unincorporated association known as the National Electrical Manufacturers' Association, and to promote and protect the interests of electrical manufacturers and others dealing in or supplying electrical goods in the United Kingdom. The word limited is omitted from the title by license of the Board of Trade. The management is vested in a committee, the first members of which are H. Bevis, T. J. Grainger, P. A. Lundberg, F. H. Nalder, C. S. Northcote, H. Oppenheimer, S. Paterson, and W. Smith. Registered office: 5, Ridler-place, Holland-street, Blackfriars, S.E.

## PERSONAL.

Mr. Ernest Moore, of Sheffield, has been appointed, out of 125 applicants, as chief clerk in the Halifax Corporation tramway offices.

The Belfast Electricity Committee have appointed as station superintendent, at a salary of £4 per week, Mr. Moore, who is assistant manager of the similar department in Manchester.

The Swindon Town Council have abolished the post of shift engineer at the power station, and have appointed the present shift engineer, Mr. F. V. Jordan, station engineer at a salary of £104 per annum.

The Derby Town Council have increased the salary of the electrical engineer, Mr. T. P. Wilmshurst, from £500 to £550 per annum, as from May 1, 1905, and from £550 to £600 per annum, as from May 1, 1906.

We are informed that Mr. Arnold B. Gridley, having accepted an important position on the staff of the Newcastle-upon-Tyne Electric Supply Company, Limited, has severed his connection with the British Electric Traction Company, Limited, with whom he has been for the past four years as secretary of some of its associated electric supply and traction companies. On Friday last Mr. Gridley was presented with a canteen of plate and cutlery by some of the directors and staff. The presentation was made by Mr. Garcke, the managing director of the British Electric Traction Company, Limited.

## CONTRACTS FOR ELECTRICAL SUPPLIES.

**Edinburgh.**—The Corporation invite tenders for water-tube boilers. Tenders by May 8.

**Tonbridge.**—The Urban District Council require tenders for cables. Tenders by May 29.

**Islington.**—The Borough Council require tenders for coal-conveyors, etc. Tenders by May 24.

**Dublin.**—The Port and Docks Board invite tenders for an electric generating station. Tenders by May 15.

**Cataquoxes (Spain).**—The local light and power company require tenders for electrical plant. Tenders by July 1.

**Johannesburg.**—The time for sending in tenders for this contract (particulars of which appeared in former issues) is May 8 (London).

**Rosario (Argentine).**—The Government require tenders for construction and working of an electric tramway. Tenders by June 30.

**Bury (Lancs.).**—The Guardians invite tenders for electrical installation at the union workhouse. Tenders by 10 a.m. on May 8.

**Cork.**—The Electric Tramways and Lighting Company, Limited, invite tenders for the year's supply of electrical fittings. See advertisement.

**Paris.**—The Colonial Office, 4 bis, Rue Jean-Nicot, require tenders for the supply of lamps and lighting accessories for three years. Tenders by May 23.

**Cheltenham.**—The Corporation invite tenders for the supply of arc lamp carbons for the year ending March 31, 1906. Tenders by May 17. See advertisement.

**Leith.**—The Corporation invite tenders for coal elevating and conveying plant and boiler-house auxiliary plant. Tenders by May 17. See advertisement.

**Cork.**—The Cork Electric Tramways and Lighting Company, Limited, invite tenders for the supply of white wood casing and capping. See advertisement.

**Dartford.**—The Urban District Council invite tenders for the supply and erection of various plant. Tenders by May 24. Full particulars in advertisement columns.

**Liria.**—The Municipality require tenders for installation of electric lighting; 2,000 c.p. are required for street-lighting, for which it is proposed to pay 6,000 pesetas per annum.

**Dax (Province of Landes, France).**—The Municipality require tenders for their concession to erect and work electric lighting for 35 years. Tenders to the Mayor by May 14.

**French West Africa.**—The Governor-General of French West Africa, at Dakar, requires tenders for the erection and equipment of a central station at that place. Tenders by May 15.

**Laventhem (Belgium).**—The Municipality require tenders for erection of central station, laying of mains, etc. Particulars (3s. 4d.) may be obtained from the Secretary of the Mayor of that place.

**Kettering.**—The Urban District Council invite tenders for the supply, delivery, and erection of Nernst lamps, posts, etc., for street-lighting within their district. Tenders by May 29. See advertisement.

**Antwerp.**—Tenders will shortly be invited by the Belgian State Railways for the installation of electric light in their local railway station. Specification No. 619 may be obtained from the Government Railways Office, Brussels.

**Paisley.**—The Gas Corporation invite tenders for the following plant: (Contract 5) electric power generating plant, consisting of gas-engines and dynamos; (Contract 6) elevated electric coke conveyors, electric screening plant, coke storage hoppers, etc. Tenders by May 13.

**Switzerland.**—M. R. Vontobel, of Winterthour, and M. Charles Probst, of Lucerne, have obtained a concession for the construction of a narrow-gauge electric railway from Meiringen to Gletsch. The total cost of the enterprise is estimated at £241,600; £19,600 is to be expended on rolling-stock.

**London.**—The London County Council invite tenders for the supply, erection at its generating station, East Greenwich, S.E., and maintenance for a period of 10 years, of a battery of 280 accumulator cells having capacities of 645 ampere-hours at a three-hour discharge rate and of 450 ampere-hours at a one-hour discharge rate. Tenders by May 16. See advertisement in last issue.

**Irvine (Scotland).**—The Corporation invite tenders for the supply and erection of the following plant: (Contract 1) buildings; (Contract 2) power-house plant—(Section A) suction gas plant, gas-engines, and generators; (B) balancers and boosters; (C) battery of accumulators; (D) switchboard; (E) crane; (Contract 3) mains—(Section A) cables, trenches, etc.; (B) converting street lamps; (C) meters. Tenders by May 15.

**London, N.**—Tenders are invited for the road work, platelaying, and paving, etc., required for the construction for electrical traction on the overhead trolley system of the short length, equivalent to about three-fourths of a mile of single track, of authorised tramway in Archway-road, Highgate, between the Archway Tavern and the

Digitized by Google

Highgate Archway, in the metropolitan borough of Islington, for the London County Council. Tenders by May 8.

**London, S.E.**—The London County Council invite tenders for the road work and plate-laying required for the construction, for electrical traction on the conduit system, of certain authorised tramways in Blackwall-lane, East Greenwich, and from New Cross to Lewisham, and for the reconstruction, for the same system of electrical traction, of a portion of the existing horse tramways in Woolwich-road, and from Lewisham to Catford. Tenders by 10 a.m. on May 25.

**Heywood.**—The Council invite tenders for (A) Lancashire boiler, feed pump, hot-well, two water-filters, steam feed and blow-off pipes; (B) two 200-kw. steam dynamos, condenser, air and circulating pump, hot-well pump, water-cooling tower, exhaust and circulating pipes, oil separator and pumps; (C) traction switchboard, extensions to lighting board, cable connections, etc.; (D) traction feeders, telephone and test wires, switch pillars. Tenders by May 17. See advertisement.

## RESULTS OF TENDERS.

**Belfast.**—The Council have accepted the tender of Courtenay and Co., at £6,281. 14s. 5d., for the erection of the pump-house in connection with the generating station.

**Belfast.**—It is proposed to order 30 tramway cars from the Brush Company, and, in addition to convert 25 of the best horse cars into electric cars at a cost of £350 for each car.

**Metropolitan Asylums Board.**—The tender of J. W. Gray and Son, of 115, Leadenhall-street, E.C., at £670, for the installation of electric fire-alarms and telephones at the Gore Farm Upper Hospital, has been accepted.

**Generators.**—Johnson and Phillips, Electric Light and Power Works, Old Charlton, report recent orders for 400-kw. traction generator and switchboard extension for the Barking Urban District Council, and 150-kw. and 50-kw. generators for dye works.

**Middlesex Tramways.**—The Light Railways and Tramways Committee have given the work connected with the tramways from Tally Ho! Corner to Woodberry-grove, Ballards-lane, Finchley, and the extension of the tramways from the Edgware-road, Cricklewood, to the Metropolitan Railway Station, Willesden, to C. Ford, contractor, and Dick, Kerr, and Co., Limited, contractors, respectively. The work, which consists of double tracks, wood paved, is to be carried out under schedules and prices, to the satisfaction of Mr. H. T. Wakelam, M.I.C.E., the county engineer.

**Aston Manor.**—The Corporation have received the following tenders for tramway construction:

| | | | |
|---|---|---|---|
| G. Trentham (accepted) | £51,236 | 3 | 9 |
| Dick, Kerr, and Co., Limited | 51 849 | 1 | 10 |
| G. Law | 52 912 | 7 | 6 |
| J. G. White and Co. | 52,357 | 15 | 9 |
| Underwood and Bro. | 53,387 | 7 | 6 |
| Griffiths and Co., Limited | 54,073 | 9 | 6 |
| Graham and Sons | 54,162 | 0 | 0 |
| Krauss and Son | 56,552 | 5 | 0 |
| J. White, jun. | 59,112 | 7 | 7 |
| G. Holloway | 61,572 | 5 | 0 |
| Blackwell and Co., Limited | 61,785 | 12 | 0 |

The prices represent the net amount of tender after deducting the value of old materials.

**Erith (Kent).**—The Urban District Council have received the following tenders for the wiring of their car depôt and workshops:

| | | | |
|---|---|---|---|
| W. Dickinson and Co., Highfield, Bexleyheath (accepted) | £200 | 15 | 6 |
| J. E. Collum and Co., Ipswich | 206 | 15 | 6 |
| A. H. Marshall and Co., Leytonstone | 215 | 10 | 0 |
| Owens Ironmongery Stores, Limited, Erith | 221 | 18 | 6 |
| Cross and Cross, Walsall | 229 | 6 | 0 |
| Barlow and Young, London-street, E.C. | 300 | 0 | 0 |
| J. T. Jarvis and Sons, Erith | 307 | 0 | 0 |
| Private Wire and Telephone Installation Company, Westminster, S.W. | 329 | 18 | 0 |
| Lancashire Electrical Engineering Company, Ashton-under-Lyne | 330 | 0 | 0 |
| D. Hulett and Co., High Holborn, W.C. | 331 | 10 | 6 |
| W. Parker, Gillingham | 350 | 0 | 0 |
| S. E. Haward and Co., Limited, Tunbridge Wells | 361 | 4 | 0 |
| W. H. McKone and Co., Berners-street, W. | 362 | 14 | 0 |
| Dudley Electrical Company, Dudley | 363 | 0 | 0 |
| Star Electrical Engineering Company, Bridgwater | 389 | 17 | 0 |
| Beam Company, Barbican, E.C. | 458 | 0 | 0 |

**Dublin.**—The Corporation have received the following tenders for supply and erection of two electric motors:

| | | | |
|---|---|---|---|
| Aston Bros., Limited, Dublin (Lahmeyer Electrical Company) | £172 | 8 | 0 |
| Vickers, Sons, and Maxim | 178 | 0 | 0 |
| Bruce Peebles and Co. | 185 | 0 | 0 |
| British Westinghouse Electrical and Manufacturing Company, Limited | 196 | 0 | 0 |
| Johnson and Phillips | 197 | 10 | 0 |
| Electric Construction Company, Limited | 198 | 0 | 0 |
| Wm. Coats and Son, Limited (General Electric Company, (1900) Limited) | 210 | 0 | 0 |
| General Electric Company, Limited | 222 | 10 | 0 |
| Industrial Engineering Company | 233 | 6 | 0 |
| Brush Electrical Engineering Company | 236 | 5 | 0 |
| Aston Bros., Limited (Lahmeyer Electrical Company and Orlrey Gear) | 235 | 18 | 0 |
| Lancashire Dynamo Company | 240 | 0 | 0 |
| British Thomson-Houston Company | 270 | 5 | 0 |
| Maschinenfabrik Oerlikon | 276 | 10 | 0 |
| Oerlikon (withdrawn) | 288 | 10 | 0 |

**Derby.**—The Town Council have accepted the following tenders: St. Helens Cable Company, feeder cable £860. 17s. 1d., distributing bitumen cable £438. 12s. 6d.; S. R. Turner and Co., lathe £38. 0s. 6d., pillar drilling machine £34. 2s. 6d.; C. A. Parsons and Co., steam turbine, £3,950; British Thomson-Houston Company, switchboard extension, £287.

**Nuneaton.**—The following tenders have been received for supply and delivery of cables and joint-boxes, for the Electricity Committee:

Vulcanised-bitumen cables.

| | | | |
|---|---|---|---|
| W. F. Dennis and Co.* | £641 | 15 | 6 |
| St. Helens Cable Company | 838 | 10 | 4 |
| Callender's Cable Company | 843 | 0 | 0 |

# BUSINESS NOTES.

## TRACTION.

**Brighton.**—The returns for the Corporation tramways for Easter week show the takings to have exceeded those of last year by more than £400.

**Gloucester.**—The revenue for the first year totals £15,815, and there is a net profit of £273 after making provision for special expenditure.

**Dalkeith.**—The Town Council have provisionally agreed to give their consent to the Edinburgh Suburban Electric Tramways Syndicate's scheme.

**City and South London Electric Railway Co.**—This company announce "great reduction in fares," also abolition of certain restrictions concerning return tickets.

**Maidstone.**—The enquiry by the Light Railway Commissioners into the proposed line between Maidstone and Headcorn has been completed. The Corporation opposed.

**Spain.**—The Grenada and Murcia Tramways Company have received the concession to construct and work the electric tramway from Murcia to Palma. The Malaga Tramways Company propose to construct two lines in Malaga.

**London United Tramways Co.**—A start was made on Monday with the work of construction over Kingston Bridge in connection with the company's scheme of electric tramways for linking Surrey with its existing Middlesex system.

**Chili.**—The Government have decided to grant a concession for constructing and working an electric railway from Valparaiso through the Casablanca and Cura Cavi Valley to Santiago, with a branch to Melifilla. As usual, the material may be imported duty free.

**Bournemouth.**—The Corporation tramway accounts show an excellent result for the past year's working. The total income amounted to £55,333, and the working expenses reached £33,592. After deducting capital charges, etc., there was a net balance of £5,201. The number of passengers carried was over 10 million.

**Birkenhead.**—The special committee appointed to consider whether some system could be devised whereby the ferries and tramways could be worked together with greater advantage to the public, has drawn up a report in which they recommend an experimental issue of reduced through return tickets available over the Higher Tranmere tramway route and the Woodside Ferry, also certain reductions of fares.

**Swansea.**—The first week's traffic on the augmented tramway system shows a large increase, the number of passengers carried being 175,000, compared with 90,000 in the corresponding week of last year. A settlement between the Corporation and the company regarding the price of current and the overhead equipment on the Morriston section seems probable. The new extensions, with the exception of the Port Tennant section, were opened to the public on Saturday morning.

**Metropolitan Electric Tramways, Limited.**—The company have issued an illustrated guide to their service between Edgware and Cricklewood. The various beauty-spots and places of interest are picturesquely shown, which, with the time table attached to the guide, will doubtless render the pamphlet highly popular. The Welsh Harp, the attractions of Hendon, and the old-fashioned town of Edgware are all duly depicted, and now that the long days have come there will doubtless be crowds of passengers anxious to explore the country covered by this line.

**Blagdon and Pensford Light Railway.**—Great interest is being displayed in the endeavour to procure an order for the construction of the Blagdon and Pensford light railway. The work of surveying the proposed route is all but completed, and at a public meeting held last week to support the scheme the following resolution was carried unanimously: "That this meeting is of opinion that the proposed light railway will greatly conduce to the prosperity and trade development of the district, and will greatly assist the agricultural, mining, and other industries, and pledges itself to support the proposed railway by every means in its power."

**Tramways and Light Railway Estates.**—At the sixth annual general meeting of the Tramways and Light Railway Estates Company, Mr. Emile Garcke, who presided, said that the profit was somewhat less than in former years, and was entirely due to the slackness of trade generally, and to the fact that the amount of work carried on by tramway companies in connection with new promotions and the construction of new lines had been very much reduced—so much so that the total fees for the year only amounted to £1,100, instead of £1,400 for the preceding year. Expenses were practically the same, being £815, instead of £835 for the previous year—a difference of £20.

**Northampton.**—Notwithstanding that the electric trams have been running only eight months, and sundry other drawbacks, the year's working of the Corporation trams shows a net profit of nearly £1,000. The account shows fares received £16,469. 5s. 1d., and a few small items making the total receipts £16,869. 8s. The expenditure on working was £9,611. 19s. 1d., leaving a gross profit for the year of £7,257. 8s. 11d. Besides allowing for interest and sinking fund, the committee purpose allocating 100 guineas towards the preliminary expenses of the undertaking and putting by £333. 6s. 8d. for reserve for third party risk. The Corporation and its officers are to be congratulated upon this excellent result.

**Nuneaton Light Railway.**—The promoters of the Nuneaton light railway scheme have given notice of their intention to apply to the Board of Trade for a further extension of time, for one year from the 26th inst., within which to construct the works authorised by the order. The Nuneaton and Chilvers Coton Urban District Council have been approached with a view of their waiving opposition to the application, but so far that authority has not expressed an opinion for or against. Under the original order work should have commenced 12 months ago. The promoters obtained an extension of one year, which expires on the 6th inst., and up to the present nothing has been done towards carrying out the scheme.

**Belfast.**—At the weekly meeting of the Tramways Committee some discussion took place in regard to the harbour tramways on the Queen's Quay. The Lord Mayor, as chairman of the Harbour Trust, explained that a deputation from that Board would wait upon the committee at an early date, and in view of this fact it was decided to postpone this matter also. In response to a letter received from the Municipal Electrical Association, it was decided that Mr. M'Cowen should represent the Corporation at the meeting in June. Mr. Nance reported that he had received the Board of Trade's approval to the portions of the lines which had been relaid, and that there were now 173 cars ordered. He had made a re-examination of the number that would be required when electric traction was started, and he found that they would need 220 cars. The committee will consider this matter.

**Kirkcaldy.**—At the monthly meeting of Kirkcaldy District Committee on Saturday plans for the Wemyss tramway scheme were submitted with information in regard to the mode of construction. Captain Wemyss pointed out that the public roadway was very narrow from Bowhouse almost to East Wemyss, and if the tramways were once laid it would be a very expensive matter for the committee to have the road widened. If the committee were prepared to widen the road at present by 8ft. or 9ft., he would give them the necessary ground free of charge. He understood they had not power to borrow money for that purpose, but should the committee give him a mandate that they would repay the money in a period of about 30 years he would advance the sum required for the purpose. A committee was appointed to look into the whole matter, and report on the advisability of widening the road.

**Potteries Light Railways.**—At a meeting of the Highways Committee of the Stoke Corporation the town clerk reported that he had written the company requesting them to make arrangements for the alteration of the rails to suit the altered roadway levels in Church-street, occasioned by the recent improvements, and that he had received a reply that the company could not agree to the relaying of the tramway as suggested. The clerk was instructed to write the manager again on the matter. The town clerk read a letter from the company in reply to the Council's complaint of obstruction of the highway by cars, and he was instructed to again write the company upon this point also. The regulations proposed to be made by the Board of Trade as regards electric power (overhead trolley system) on the Potteries Light Railways, the North Staffordshire Tramways, and the Potteries Extension Tramways were considered. The committee approved of these, subject to certain suggestions which the town clerk was instructed to lay before the Board. A hackney carriage license has been granted to the tramway company for their motor omnibus. It appears that the Corporation may resort to litigation in connection with the alteration of levels in Church street, but as it is thought that the company are anxious for a concession to enable them to bring their loop from Wolfe-street to the Monument more on the level, a compromise may be arranged.

**Halifax.**—An elaborate statement has been prepared by the tramway officials, showing the receipts for Easter, 1905, and the corresponding results for 1904. A special point is rightly made of the weather, this being a highly important factor in the success of holiday traffic. On Good Friday the receipts amounted to £192. 12s., compared with £174. 2s. 8d. on the same day last year, when the weather was showery. Saturday brought in £440. 12s. 3d., against £388. 6s. 4d. on the corresponding Saturday of 1904, which was a wet day. Sunday's takings also showed an increase—viz., £156. 10s. 1d., in place of £130. 5s. 5d. a year ago. "Fine" is placed opposite Easter Monday and Tuesday both in 1904 and 1905, with the single qualification of "windy" for last Monday. The totals show an advance, for on Monday £549. 10s. was netted, against £458. 7s. 11d. last year, and on Tuesday £498. 3s. 2d. was received, which is considerably more than the £342. 12s. 7d. registered before. Adding these sums together, it is found that with an extended mileage the trams brought in £1,837. 7s. 6d. this year, against £1,493. 14s. 11d. last year, but of this increase £343. 12s. 7d. must be put to the credit of the new Hove Edge to Brighouse, Bailiffe Bridge, and Triangle routes. A line from the borough boundary at the Calder and Hobble Inn to the Stainland and Saddleworth-road, West Vale, is to be constructed with double lines at a cost of £7,291. 15s. A long discussion took place on a resolution moved by Alderman Hey, chairman of the Tramways Committee, authorising the purchase of two motor 'buses at £950 each, as soon as the Corporation is authorised to run such 'buses. It was stated that the 'buses would be used for the Wainstall district. The resolution was passed by 21 votes to 18.

**New York.**—The Rapid Transit Commission has adopted the recommendations made by the Brooklyn Rapid Transit Company for tunnel routes and the application of the Interborough Rapid Transit Company for two additional tracks on the Second-avenue elevated line. The suggestions made to the Rapid Transit Commission by the Brooklyn Rapid Transit Company regarding routes for the Brooklyn extension were all adopted at a meeting of the commission on Tuesday, at which the new routes were incorporated into the proposed system. The offer of the New York City Company to bid for new routes was only for lines in Manhattan and the Bronx. The proposed improvements on the Second-avenue Elevated by the Interborough Company, in general terms, consist of adding two overhead tracks in the Bronx district, from One Hundred and Fiftieth-street to the Harlem River, adding two overhead tracks to the bridge across the Harlem River, and continuing such overhead tracks to One Hundred and Twenty-second.

Digitized by Google

street, where they will reach the present grade of the elevated structure. From One Hundred and Twenty-second-street South to First-avenue and Third-street there will be four tracks at the present grade of the Manhattan Railway. At First-avenue and Third-street it is proposed that the centre tracks, to be used for express purposes, shall descend and enter a tunnel which is to be placed in private property to terminate at West and Chambers streets in a loop. Action on this proposition was postponed by the Board. An alliance is announced between New York City railway interests and the New York, New Haven, and Hartford Railroad concerning mutual use of the former's proposed subways. The plan includes the transfer of passengers from New Haven trains at Willis-avenue so that they can take the New York City Company's subway, and thus run into the heart of the city with the privilege of transferring to any of the surface lines of the New York City Company—*Electrical World (N. Y.)*.

**Heywood.**—Terms have now been agreed by committees of the Bury and Rochdale Corporations with Heywood, subject to confirmation by their Councils, for the running of electric trams between these towns. These terms read as follows: (1) Heywood to construct and maintain the track, to electrically equip, and to supply current. (2) Bury and Rochdale to furnish cars and staff sufficient to give a quarter hour's service or as may be mutually agreed upon. (3) Receipts earned upon the section within the borough of Heywood to be handed over to Heywood quarterly. Heywood to pay quarterly 4½d. per car mile run on the section. (4) Bury and Rochdale to repair and maintain in good working condition the overhead equipment. The equipment to be approved and passed by the electrical engineers for Bury and Rochdale. Feeder cables excepted from this clause. (5) The number of cars required to work the whole of the Heywood system will be six; to work the portion from Heap Bridge to Heywood Parish Church four; and Rochdale boundary to Heywood Parish Church two cars. (6) These six cars shall at the end of the tenancy be taken over by Heywood, together with the unpaid debt upon such cars. (7) During the tenancy Heywood shall pay interest and sinking fund upon the whole of the cars on the whole system worked and owned by Bury and Rochdale proportionately to the car miles run upon the Heywood section. Bury and Rochdale to repair and maintain the cars during the tenancy. (8) Heywood to pay rates and taxes on the portion of the undertaking within the borough of Heywood. (9) The tenancy to be for three years certain, subject to six months' notice on either side. (10) Any matters in dispute during the tenancy and which the parties to this agreement may be unable to mutually settle shall be referred to an independent tramways manager to be appointed by the president of the Municipal Tramways Association, whose decision shall be final.

**Leeds.**—The Tramways Committee met on Monday for the purpose of considering a statement prepared by the tramways manager (Mr. Hamilton) as to the revenue and operating expenses for the year ended March 25 (of which we have already given an outline) The total revenue for the year was £298,233. 7s. 5d., which worked out at 10·151. per car mile run, as compared with £280 562. 16s. 3d., or 11·05d. per car mile run in the preceding year. The mileage run was 7,044 838, as compared with 6,091,407 in the previous year, this increase of some 16 per cent probably accounting to a considerable extent for the reduction in the earnings per car mile. Notwithstanding the increase in the mileage, the total expenses for traffic only amounted to £83,005. 12s. 2d., as compared with £79,869. 11s. 1d. in the preceding year, an increase of 4 per cent. only. The cost per car mile, owing to improved traffic arrangements, has been reduced from 3·15d. to 2·82d., which represents a saving in working expenses of over £9,000. General expenses, repairs, and maintenance were about the same as last year, except that there was an increased expenditure in respect of the permanent way of over £8,000. The total working expenses were £161,297. 3s. 7d., leaving a gross profit of £136,936. 3s. 10d. From this there must be deducted fixed charges for interest on capital, £31,691. 10s. 5d.; redemption fund, £28 501. 13s.; income tax and depreciation, £20,743. 0s. 5d.; leaving a surplus of £55,000, which the committee decided to hand over to the Finance Committee. Last year the total working expenses were £148,821. 12s. 5d., and the gross profits £131,741. 3s. 10d. The committee considered the result of the year's working to be highly satisfactory, particularly in view of the fact that trade during the Corporation's past financial year has been much depressed. Though there is a profit of £55,000 to be handed over to the Finance Committee, the ultimate fate of this sum appears to be a matter of some uncertainty until the Finance Committee arrive at a full statement of the financial position of the city, which is reported to be in a somewhat unpleasant position owing to change of party in the Corporation.

**Fatal Accidents.**—An enquiry into the circumstances connected with the death of Mr. William Williams, master of Whiston Workhouse, while travelling on the St. Helens Electric Tramway Company's system, was opened on Saturday. Richard Prescott, contractor, of Dragon's-lane, Whiston, stated that he was travelling on the car with deceased from St. Helens. All went well until they had turned the corner of the bridge in Warrington-road, Rainhill. They were riding on the top of the car, deceased being seated on the left side on the end seat at the back of the car, and witness was facing him. Witness heard a crash, and as he bent forward something struck him on the back of the head and knocked him forward. When he recovered himself he saw deceased falling down the steps of the car. Deceased was terribly injured. They were travelling at an ordinary speed, and he noticed nothing unusual in the running of the car. The standard, which would weigh about half a hundredweight, was torn up. The car travelled about twice its own length after the crash. Witness did not see anything which would lead him to believe there was any negligence on the part of anybody. In witness's opinion, if the standard had been bolted through the roof of the car, it would not have been torn out, but something else would probably have given way. The driver of the car explained that when he heard the crash he stopped the car, for they were travelling slowly down the incline on the straight, after having just turned the curve. Deceased was lying halfway down the steps leading to the top of the car, the trolley pole was lying on the road, and the standard was torn off the car and was leaning upside down over the side rails. In witness's opinion the trolley must have left the wires and caught in the cross wires. In reply to a question, the witness stated that he was warned by Inspector Wallace not to go round the curve more than six miles an hour. Witness added that he did not think any inattention on the part of the conductor had caused the accident. The conductor stated that he held the rope as the car went round the bend. The car travelled 20 yards after he released his hold of the rope up to the accident happening. Replying to a question, witness said his explanation was that the trolley head must have come off the wires and caught in the insulators. After a short retirement, the jury returned a verdict of accidental death, and exonerated the driver and conductor from all blame. Mr. Greer, on behalf of the tramways company, tendered their sympathy with the relatives in the unfortunate accident.

**Folkestone.**—At a meeting of the General Purposes Committee the following letter from the Traction and Power Securities Company, Limited, was read: "As the extended time for the construction of tramways under the Folkestone tramways order will lapse in the course of a comparatively short time, we beg to state that we are disposed to consider with you the question of entering into an agreement with your Corporation to apply next May for a light railways order for the construction of tramways within your borough along such routes as may be mutually agreed upon. We shall be prepared to repay the sums already expended by you not exceeding £1,200, provided you give us your assistance and support before the Light Railway Commissioners, as we understand from Mr. David Cook you may be prepared to do, and that we obtain the order. We are in a very good position financially and technically for carrying out such work, the whole of the materials for which would be of British manufacture. Our share capital amounts to £2,000,000, and we are associated with the British Westinghouse Electric and Manufacturing Company, Limited, whose share and capital loan amounts to £4,712,500. The latter company has supplied most of the plant necessary for the electrification of the Metropolitan and Metropolitan District Railways, and have also executed large contracts for the London County Council, the Admiralty, and the principal cities of the country, including Glasgow, Liverpool, Newcastle, Swansea, Exeter, etc. The best relations have been maintained with all of the above, and we should, of course, aim at maintaining similar relations with the Corporation of Folkestone." Subsequently the committee had an interview with Mr. D. Cook, the company's representative, who explained that as the company desired to work in harmony with the Corporation, he had been authorised to say that the company would pay in cash up to £15,000 for the expense incurred by widening the road at Radnor Park. He added that the gauge would be 3ft. 6in. That was not their choice, but they were hampered in so far that the Dover trams, the Isle of Thanet trams, and the Hastings trams were on a 3ft. 6in. gauge. If it was to be a through system, as it would be in the future, it must be all the same right through. It was decided that the matter should be referred to the Tramways Sub-Committee to deal with it at an early date. Later it was decided that the sub-committee should also take into consideration the advisability of inviting proposals for the construction of tramways in accordance with the Council's order, and when constructed to take a lease of the same.

**St. Helens.**—Labour troubles have dislocated the local tramway system, and the manager, cashier, and other members of the clerical staff have had to quit the desk for the driver's seat on the car. Even so, it has been impracticable to run many cars. St. Helens is largely an industrial centre, and the trade unions have ordered a boycott of the cars, and it is reported that the miners have threatened to wreck the vehicles and throw the drivers and guards into the canal if the cars are run by "outsiders." Several unpleasant incidents have occurred. One car was stoned, and in another the window was smashed by a woman who flung her clog through it. As an instance of the feeling exhibited, it is reported that hundreds of miners walk seven miles daily to go to and return from the pits rather than ride in the cars. On Saturday negotiations were in progress between the directors and the men's representatives in the hope of a settlement being arrived at, but the efforts proved to be in vain, and throughout the day not more than seven or eight cars were running. Early in the morning Councillor Jackson and Secretary Marshall, the men's representatives, paid a visit to Liverpool to confer with Mr. Jacob Atherton and other directors of the tramways company, and to convey to them the strikers' decision not to accept the terms offered them on Friday. The men asked that all drivers starting service should commence at 5d. an hour, with an increase of ½d. per hour at the end of six months, eventually reaching a maximum of 6d., and that conductors should commence at 4d., rise to 4½d. at the expiration of six months, and afterwards receive a maximum wage of 5d. per hour. They also seek a guaranteed average of 60 hours per week in six days; that all spare men shall receive 2s. each day they are not working; that Sundays and holidays, when working, shall be paid at time and quarter rate; that sufficient time be allowed for every journey without infringing upon the Board of Trade regulations; and that drivers and conductors be allowed 15 minutes to sign on, and 10 minutes to be allowed for conductors to pay in. On all points the directors agreed with the exception of the wages question. They proposed that the men's representatives should confer with them at the end of six months in the hope of a settlement being arrived at. In the event of this not being satisfactory, they agreed to the point being settled by arbitration. Subsequently a meeting of the men was held, but they were still firm in their determination not to accept the revised terms. They

Digitized by Google

now oppose the question of arbitration on the ground that they have twice offered to submit to arbitration, and it had been refused by the directors.

## LIGHTING AND GENERAL.

**Derby.**—Application is to be made for a loan of £350 for street-lighting.

**Gravesend.**—The Board of Trade have issued a draft order for the extension of the electricity system to Northfleet.

**Belfast.**—It has been decided to extend the electric main from Carlisle-circus to Cliftonville at an outlay of £575.

**Loughborough.**—The electrical engineer has been asked to fully report upon the question of free wiring the better-class houses in the borough.

**Frome.**—Sanction has been obtained to a loan of £6,900 for the purposes of electricity, and £230 for the erection of additional lamps in the town.

**Bridlington.**—The number of fresh applications for electrical energy during the month was 17, bringing the total number of consumers to 110.

**Removal.**—Messrs. Buchan and Hogarth have removed their Edinburgh offices to 16, Rutland-square, the telephone number remaining 2,562 as before.

**Beaconsfield (Cape Colony).**—The Town Council are about to ask Parliament for powers to erect an electricity supply station for public lighting and power supply.

**Erith.**—The Electric Lighting and Tramways Committee has been constituted as follows: Councillors Button, Cannon, Charlesworth, Ling, Palmer, Stebbings, and Turner.

**Chester.**—The recommendations of the Lighting Committee given in our last issue have been adopted with the exception of No. 6, which recommended the establishment of a showroom.

**Globe Telegraph and Trust Co.**—The directors announce a final dividend of 4s. 9d. per share on the ordinary shares, making a total distribution of 5¾ per cent. for the year, carrying forward about £1,600.

**Llandilo.**—The Urban District Council have appointed the following to be an electric light committee: The Chairman, Vice-Chairman, Mr. T. C. Thomas, Mr. Rees Griffiths, Mr. J. Young Davies, and Mr. D. Williams.

**Constantinople.**—A Reuter dispatch says the convention for laying the Kusterji-Constantinople cables has been signed with the German Eastern Telegraph Company. The work of laying the cable will begin shortly.

**Pendlebury.**—The Acme Spinning Company are building at Pendlebury, near Manchester, a mill which will contain about 80,000 spindles, and will cost nearly £100,000. The machinery is to be driven by electricity.

**Reading Exhibition.**—The Reading Electrical Exhibition has proved a great success, both as regards attendance and the excellent variety and interesting character of the contents of the exhibition. A description of the exhibits appeared in our last issue.

**Stafford.**—The Town Council have decided that the price of electricity for power purposes be 2½d. per Board of Trade unit, subject to the following discounts—namely: under 200 Board of Trade units per quarter, 2½ per cent.; over 200, 50 per cent., with a minimum charge of £2 per quarter.

**Swindon.**—At the Tuesday's Council meeting some discussion arose upon recommendation of tenders for wiring consumers' houses. It appears that there were four local tenders, and that the tenders were amended ones and that all quoted the same figures. Finally, the matter was referred back to committee.

**Worksop.**—The income of the electric lighting undertaking last year from all sources was £2,860, paid by 1,985 consumers, and the expenditure was £1,718. This year's profit on the undertaking is stated as £1,142, equal to 4¾d. per cent. on the capital. As compared with last year, the expenditure on electricity has increased by £289 and the income by £623.

**Grays.**—An enquiry has been held into the application of Grays Urban District Council for sanction to borrow £6,000 for purposes of electric lighting. Messrs. W. A. Brown (chairman of the Lighting Committee), W. H. Umfreville, and T. Banks, clerk to the Council (Mr. C. Asplin), surveyor (Mr. A. C. James), and electrical engineer (Mr. E. D. Long) gave evidence.

**Sir Hiram Maxim Electrical Company, Limited.**—Capital, £50,000. Object: to acquire from the Peddie Small-Arms Corporation, Limited, the business and property recently acquired by that company from the Sir Hiram Maxim Electrical and Engineering Company, Limited, to acquire any other concessions, rights, or properties, and to carry on any business connected therewith.

**The Zambesi Bridge.**—It is reported that the bridge at the Victoria Falls will be completely riveted, painted, and finished by the middle of June. Fifty miles of railway north of the Falls were constructed before the material could be taken across the bridge, the locomotives, trucks, rails, sleepers, and other necessaries being carried across the gorge by means of the electric transporter.

**Government Telephones.**—In the House of Commons on Wednesday Lord Stanley moved that a Select Committee be appointed to consider the agreement between the Postmaster-General and the National Telephone Company. There was some opposition to the motion as framed, and, there being an arrangement that no contentious matter should be taken after the Budget resolutions, Lord Stanley withdrew his motion.

**Eastbourne.**—The work of laying the new mains in Seaside and Langney-road is to be proceeded with up to June 9 next, and discontinued the same day until Sept. 20. The Council have accepted an offer of the Underfeed Stokers Company to equip one of the Stirling boilers with a mechanical stoker with a fan for forced draught, a motor to drive the fan, and all work in connection with the erection thereof for a three months' trial free of cost.

**Bradford-on-Avon.**—Messrs. Edwards and Armstrong, electrical engineers, Bristol, propose introducing an electric lighting scheme for the villages of Winsley and Turleigh, if permission can be obtained to lay the cables through or across the streets. The Parish Council have resolved to support the scheme, and to recommend the Rural District Council to do likewise, subject to proper conditions being arranged. The Rural District Council have agreed to support the scheme so far as it is in their power.

**Stock Exchange.**—The Stock Exchange Committee have ordered the undermentioned securities to be quoted in the official list: Measures Bros., Limited, further issue of 25,507 ordinary shares of £1 each fully paid, Nos. 210,001 to 235,507. Applications have been made to the committee to appoint a special settling day in and to grant a quotation to the British Columbia Electric Railway Company, Limited, further issue of £100,000 preferred ordinary stock and £90,000 deferred ordinary stock.

**Huddersfield.**—It has been decided to extend the mains to the Mount, Outlane. The borough electrical engineer in his last report states that the number of consumers in April was 2,085, an increase of 15 on the preceding month, and that the number of lamps connected in April was 142,775, an increase of 571 on the month of March. On March 31 90,441 yards of primary mains and 66,227 secondary had been laid. The Council on Wednesday decided to return their telephone licence to the Postmaster-General.

**London Gazette.**—The last day for receiving proofs in the estate of William Watson and George Huntington, electricians, 83, Battersea-rise, London, is May 13. A receiving order has been made out on creditor's petition in the estate of Harry John Salter, electrical engineer, 235, High Holborn, London. The first meeting in the estate of Arthur Driffell Poulter, printers' and electrical engineer, 22, New Bridge-street, London, will be held at 24, Railway-approach, London Bridge, S.E., on May 12, at 12.30 p.m.

**Lancaster.**—The Electricity Committee have been unable to accede to the request of the Lighting Committee to reduce the price of electricity for street-lighting. They found that when the actual charges had been taken off it only left them a penny and a little over a third per unit for the current used. Compared with 5d. per unit charged to ordinary consumers for lighting purposes, the reduced price of 2½d. per unit charged for current for motors, and 2d. per unit charged to the Tramways Committee, it appears that the amount paid by the Lighting Committee is very moderate.

**Wolsingham.**—The Wolsingham Steelworks have been fitted with electric plant, the main contractors being Messrs. Bruce Peebles and Co., of Edinburgh. The installation consists of three Lancashire boilers, working at 160lb. pressure per square inch, and two high-speed engines by Messrs. W. H. Allen, Son, and Co., together with some 13 motors, ranging from 5 h.p. to 75 h.p. each, and a large number of arc and incandescent lamps. The power and boiler houses are erected in the centre of the works, and are fitted with thoroughly up-to-date water-softening and economising plants, and a 100ft. steel chimney.

**Middlesbrough.**—The engineer's March report shows 76,610 lamps connected and 82,074 units generated against 46,773 lamps connected in April of last year. The coal used was 330 tons, or 9.b. of coal per unit, costing ·48d. per unit, against 200 tons, or 9·81b. per unit, costing ·54d. per unit for the corresponding month of last year. The estimated revenue was £1,021 against £643 last year. The works' cost had been £302, or ·88d. per unit, against £215, or 1·13d. per unit a year ago, showing a reduction this year of ·4d. per unit. The total costs had been £458, or 1·34d. per unit, against £330 last year, equal to 1·73d. per unit, and showing a decrease this year of ·39d. per unit. The estimated profit for the month was £563.

**Southport.**—The gross profit of the Electricity Committee is £14,771, as against £14,573 for the previous year, an increase of £197. The net profit is £3,355, as against £3,616, a decrease of £260. Out of the profits of the past year, in addition to the sum of £2,500 promised in aid of rates, £284 has to be taken to make up the full charge for rates for the year 1904. The sale of current to the Tramways Committee and the company decreased by £300. The expenditure was increased by £468 for additional charges for interest and sinking fund. The income and expenditure for the past four years are as follows: (1902) income £18,493, expenditure £16,811, profit £1,682; (1903) £20,361, £18,576, £1,785; (1904) £22,002, £18,386, £3,616; (1905) £22,593, £19,237, £3,355.

**York.**—The last minutes of the Electricity Committee contained the following statement as regarding finances: gross income, £10,732; ordinary working expenditure, £5,918; extra special charges—viz., erection of offices, £924, making together the sum of £6,842, leaving a net revenue of £3,889. 17s. The amount chargeable for interest and sinking fund has been £6,835, which leaves a net deficit of £2,946 to carry to reserve fund account. The committee have submitted a statement as to the cost of working the destructor for the year ended March 31 last, showing the net amount to be £901, which together with the deficit balance at April 1—viz., £973—makes a total deficit at March 31 last of £1,874. In regard to the above deficiency of £2,946 the committee recommend that the cost of the new offices—viz., £924—be included in and defrayed out of the ensuing year's rates, and that they be authorised to carry over the balance—viz., £2,021—to a suspense account for two years.

**Durham.**—The Durham Collieries Electric Power Company, Limited, are about to supply Hetton Coal Company's collieries. It is proposed to use the current for hauling, pumping, coal-cutting, light

Digitized by Google

ing, etc., at the company's extensive collieries at Eppleton, Lyons, and Elemore. The power company will also supply the collieries of the Lambton Collieries, Limited, as well as the estate of the Earl of Durham. The large power station which is being erected at Philadelphia, near Penshaw, will supply at least 12 collieries, and the 15 miles of tramways belonging to the Sunderland District Tramways, Limited, as well as the lighting of the urban districts of Houghton-le-Spring and Hetton-le-Hole, and the district embraced in the area of the Easington Rural Council, owned by the Houghton-le-Spring and District Electric Lighting Company. The contracts have been arranged by Messrs. Harper Bros. and Co., consulting engineers, London, and Messrs. D. Balfour and Son, engineers, Newcastle-on-Tyne. Power will be available by the end of the year.

**Edinburgh.**—The following tariff has been agreed to as from May 15: private electric lighting, 3½d. per unit; public lighting, £10. 15s. per annum for present arc lamp, and £10 per annum for new arc lamps, and motor power 1½d. per unit. On Tuesday the Council considered a recommendation of the Cleaning and Lighting Committee that 1,950 of the present gas lamps for street-lighting should be converted into incandescent gas lamps, at an estimated initial cost of £4,022 and a permanent annual cost of £788. 2s. 6d. Consideration of the matter had been delayed from the last meeting of the Council. Councillor Stevenson, convener of the Electric Lighting Committee, moved as an amendment that of the sum of £4,022 to be placed in the estimate for improved street-lighting, £2 000 should be allocated for the purpose of providing 200 electric arc lamps in suitable thoroughfares throughout the city. Ultimately it was agreed to recommit the subject, on the understanding that Mr. Stevenson should submit his scheme of electric street-lighting to the Cleaning and Lighting Committee, and that afterwards the matter would be determined by the Council.

**Stoke-upon-Trent.**—The electrical engineer in his last monthly report gave the total number of consumers being supplied with electricity at March 31 as 97, including various motors aggregating 44 h.p. The committee having considered the request of the Free Library, Baths, and Museum Committee that the free library and museum should be lighted gratis, regretted they could not accede thereto at present, but undertook to reconsider the matter in the course of 12 months. The chairman has attended the Health Committee regarding the latter's complaint as to the destructor not dealing with the whole of the town's refuse, and has laid before them the engineer's statement of the weight and number of loads of refuse delivered daily during the last 12 weeks. He explained the committee's suggestions as to the supply, and considers that a more regular supply would result therefrom. The borough surveyor's final statement of the cost of the carrying out of the contract for the erection of the electricity and destructor works shows that the work has been completed for £372 less than the accepted tender, and the committee have congratulated him on the very successful and economical erection of the works. The Electricity Committee have now had five or six months' experience in which the works have been in operation, and they are well pleased and satisfied with the progress made, and had every reason to anticipate that in a short time they will be self-sustaining.

**Colchester.**—Sanction has been received to the borrowing of a further sum of £3,495 for electricity purposes. The accounts for the sixth year of working of the electricity undertaking show a gross revenue of £11,432, the working expenditure has been £5,671, leaving a gross profit for the year of £5,761. The amount paid for interest on loans was £1,682, and for redemption £1,693. After allowing for all capital charges a net surplus for the year of £2,432 remains. Private consumers have taken throughout the year 425,229 units, which yielded £7,786—an average price of 4·36d. per unit. Public lamps took 87,373 units, which yielded £871, the average price being 2·39d. per unit. These two items make a total of 513,602 units, yielding £8 657, at an average price of 4·05d. per unit. In addition there are tramways sales amounting to 286,205 units, which yielded £2,265. The price charged for this current was 2d., less 5 per cent., being equal to 1·88d. per unit. These figures would give them a grand total of 779,807 units, generated during the year, which had yielded the sum of £10,922. 19s. 9d., the average price for the whole being 3·27d. A few small items, including £362, being profit on trade account, and £147 for rent, make up a gross revenue of £11,432. 18s. 4d. In addition to the £1,693 paid away during the year as redemption, a sum of £691 has been taken from this year's revenue towards repairs and maintenance of plant, whilst £269 had been paid out of the accumulated reserve for renewals.

**City of London.**—The City of London Electric Lighting Company, Limited, have informed the Court of Common Council that the rate for the supply of electrical energy to all the public buildings of the Corporation will be reduced from April 1 to March 31, 1906, to 2½d. net per Board of Trade unit. The report of Mr. D. J. Ross, the retiring engineer, on the works executed by the public health department states that the number of overhead wires in the City has again greatly increased, in addition to the large number placed underground. In 1904 the number of private owners of overhead lines increased to 117, and of companies to 18, jointly possessing a total estimated number of 39,000 miles of overhead wires in the City, with about 682,900 spans crossing public thoroughfares, compared with 260,000 spans in 1899. The number of overhead-wire owners during the last six years is given as follows: 1899, companies 8, private firms 18; 1900, 11 and 20; 1901, 9 and 64; 1902, 12 and 75; 1903, 17 and 103; 1904, 18 and 117. The engineer says that the value of the enforcement of the by-law by the Corporation requiring proper identification of all overhead wires erected in the City, has been apparent. In the case of about 30 fallen wires reported at various times by the police, whose owners they were unable to ascertain, the inspector of overhead wires, upon being informed of the breakages, was able to identify the owners, and thus to obtain the immediate repair or removal by them of the fallen wire. The Court of Common Council on Thursday agreed to a recommendation of the Streets Committee to light (*a*) Queen Victoria-street and a portion of Queen-street between Queen Victoria street and Cheapside, (*b*) Fleet-street, and (*c*) Lower Thames-street from Fish-street-hill to Billingsgate Market and Monument-street by incandescent gas lamps in lieu of the existing electric arc lamps, on the understanding that the whole be regarded as an experiment, and that the committee proceed no further than the lamps mentioned in their report.

**Power Supply.**—There is nothing like pushing trade if you want to get it. Mr. S. E. Fedden, the general manager and engineer of the Sheffield Corporation electric supply department, has addressed the following business-like circular to likely customers in the town: "As you will probably be overhauling your engines and machinery during the coming holidays, I would draw your attention to the facilities which now exist for driving by electric power off the Corporation mains, and ask you to consider if it still pays you to use engines with their more or less complicated drives and expensive upkeep and attention. The introduction of electric motors greatly simplifies the working of a factory, eliminates much dirt and noise, and frequently sets at liberty valuable space, owing to the comparatively small dimensions of the motors and the ease with which they can be adapted to the peculiarities of buildings and existing arrangements of shafting and machines. The manufacturers of Sheffield have to-day 4,000 h.p. of electric motors connected to the mains of the Corporation electric supply department. These motors vary in size from ¼ h.p. to 120 h.p., and are working machinery of every class employed in the many industries of the city, from the lightest cutlery and silver ware to heavy steel working, general engineering, etc. The rates and charges are amongst the lowest in the country, and, together with the Corporation system of letting out motors on hire, place this cheap and convenient form of power within the reach of every works owner. The general manager will be pleased to submit estimates free for electric driving, and send competent assistants to any address in Sheffield to give information and advice generally on the subject."

**Maidenhead.**—The Thames Conservancy have now consented to accept 1s. per annum as quit rent, instead of £1 as originally asked, in respect of the cable service laid over the bridge at Boulter's Lock, and agreements have been exchanged accordingly. Mr. C. O. Milton, in his monthly report, states that the plant and mains have run well since the last meeting with the exception of an accident to the Castle-hill pilot wire on April 3, which caused a temporary disconnection of the supply. The fault was due to the bad arrangement of the pilot fuse connections, which have given trouble on several occasions. The old type of fuse block has now been removed and the fuses put into a separate iron chamber, and all the other pilot connections will be treated in the same way as soon as possible. This will eliminate the danger altogether. Applications for supply are now again coming in freely, there being about 20 new services to lay. The demand is rising very favourably in the new areas, especially in Maidenhead Court. Mr. Milton again points out the advisability of offering a maximum demand system of charging as an alternative to the flat-rate system at present used, in order to retain the custom of some of the best consumers. The March quarter's accounts show an increase of 35 per cent. on last year. Their total value was about £1 100. The engineer's recommendation to take another pupil into the works, in order that three shifts of electrical men may be run at the works, has been adopted, and the committee will consider his tariff proposals at their next meeting. An extension in Ellington-road is to be proceeded with at once, and an applicant in Taplow village will be informed that the Council intend to include in their next extension scheme that part of the area in which his house is situate. The engineer has been asked for a report showing (1) the cost of the arc lamp pillars and the rental paid by the Council therefor as distinguished from the cost per lamp inclusive of light, lighting, extinguishing, and renewals; and (2) the cost of substituting Messrs. Oliver and Co.'s lamps for those of the British Schuckert Company.

**Hull Telephones.**—The Telephones Committee of the Corporation have had under consideration the agreement entered into by the Postmaster-General for the purchase of the National Telephone Company's undertaking, and have arrived at the opinion that it was not desirable, in the public interest, that such agreement, in its present form, should come into force, and that steps be taken by the Corporation, in connection with other municipalities, to oppose the agreement, in view of the circumstances under which, and the objects for which, the Corporation established their competing system in Hull and took out their license until 1911 only, and the benefits which have resulted therefrom, both to the public and the Government, the committee is strongly of opinion that, in order to enable the Corporation to recoup themselves the capital expenditure incurred, it is only just and equitable that, in case the agreement comes into force, the Postmaster-General should undertake either to purchase the whole of their plant in 1911 or grant a renewal of their license to 1927. An enquiry has been held into a proposal by the Corporation to borrow £20,873 for the purpose of telephonic extension, more especially in the residential portions of the city. Mr. Bennett said that the telephone system had been carried out according to the plan originally submitted to the Local Government Board, although the whole of the loan previously sanctioned had not been expended. The work first undertaken had, however, been completed, and that included the alterations necessary for converting the Trippett baths into a central exchange. The system had also been carried to the villages of Hessle and Cottingham, and also to Beverley. The number of subscribers was at present 1,928. In the first place, they estimated that in the older portion of the city they would get more subscribers than had hitherto been secured; but in the residential districts there were more users than was originally anticipated, these being greatly in excess of the provision made.

**Olympia Electrical Exhibition.**—This exhibition will be held at Olympia from Sept. 25 to Oct. 21, 1905, inclusive, under the auspices of the National Electrical Manufacturers' Association (Incorporated).

Digitized by Google

Sir William H. Preece is the president, and a strong executive committee has been at work for some time, of which Mr. Walter Davenport is the secretary. The organising managers, Messrs. F. W. Bridgers and G. D. Smith, have offices at Balfour House, 119-125, Finsbury-pavement, E.C., and they have succeeded in getting together the following very representative preliminary list of exhibitors: E. P. Allam and Co., Arc Lamps Limited, Armorduct Manufacturing Company, W. and T. Avery, Babcock and Wilcox, Berliner Telephone Manufacturing Company, Berry, Skinner, and Co., D. H. Bonnella and Son, G. Braulik, British Accumulator Company, British Electric Plant Company, British Prometheus Company, Bruce Peebles and Co., Brush Electrical Engineering Company, Cory Bros. and Co., Crompton and Co., Crypto Electrical Company, Diesel Engine Company, Durtnall and Pries, Edison and Swan United Electric Light Company, Electric Flashlights Limited, Electric and Ordnance Accessories Company, Electrical Power Storage Company, *Electrical Review*, *Electrical Times*, Elliott Bros., Everett, Edgcumbe, and Co., Ferranti Limited, I. Frankenburg and Sons, Geipel and Lange, General Electric Company, High-Speed Braiding Machine Company, Improved Electric Glow Lamp Company, International Electric Company, J. Keith and Blackman Company, Lahmeyer Electrical Company, Lancashire Dynamo and Motor Company, Langdon-Davies Motor Company, A. P. Lundberg, Linolite Company, Monté Callow and Co., Nalder Bros. and Thompson, New Brotherton Tube Company, Oliver and Co., Pearson Fire-Alarm Limited, Phœnix Dynamo Manufacturing Company, Pope's Electric Lamp Company, Portable Accumulators Limited, Pritchetts and Gold, Rumney and Rumney, P. Santoni and Co., Selig, Sonnenthal, and Co., Siemens Bros. and Co., Simplex Steel Conduit Company, G. Straus and Co., Sunbeam Lamp Company, Tudor Accumulator Company, Dr. H. Traun and Sons, Union Electric Company, Verity's Limited, Western Electric Company, who have engaged space from 100ft. to 1,400ft. each.

**Elgin.**—The special committee appointed to consider as to the introduction of electricity and erecting of a gasometer have reported in favour of electric lighting. As regards the erection of an additional gasometer, the committee consider it advisable to defer erecting a new gasometer, which would save an expenditure of over £4,000, the estimated expense of such gasometer. As regards the introduction of electric lighting into the town, the committee, after making very exhaustive enquiries, point out that in every year since 1896 there has been a considerable increase in the capital invested, number of electric lamps in use, and quantity of electricity used. On looking into the question as to whether electricity pays, the committee find that the average rate of dividend for 103 companies with a capital of over £24,000,000 was 5·03 per cent., and that electric shares are now looked on as gilt-edged securities. Electricity had been successfully introduced into towns of a similar size to Elgin—amongst others: Brechin, population 9,000 (gas 4s. 3d. per 1,000 cubic feet); Montrose, 12 500 (4s. 4d.); Broughty Ferry, 10,000 (3s. 6d.); Dalkeith, 6,835 (4s. 2d.). The committee are of opinion that there is not another town of the same population as Elgin with the same advantages, nor of the same size with so many of the better class of houses and the same class of shops. The town is also compactly built together, which would enable the electric current to be distributed at less than the usual cost. Elgin has already a good water supply and drainage system, the streets and pavements are in good order, and with the installation of electric light it would be thoroughly up-to-date. With these points in view, the committee have made enquiries and have ascertained that a large number of private persons, professional men, and shopkeepers in the town are prepared to use the light in their premises if supplied at a price not exceeding 6d. per Board of Trade unit—the price suggested by the committee. The committee also found that those ratepayers who have private installations will become customers of the Corporation, and that one gentleman who is about to introduce the light for himself will await the decision of the Town Council on the matter before proceeding with his own installation. A number of customers will be obtained for power for driving machinery of various kinds, from rotary brushes to sawmills. A sub-committee who called on the citizens also found a number who are not prepared to take in the electric light at present, either because they are tenants and not proprietors of the properties occupied by them, or for other reasons, but it was found that they were all, nevertheless, in favour of the installation of electricity. In a great number of cases the hope was expressed that the Corporation would themselves introduce the light, and not allow a company to do so. In the list submitted by the sub-committee there are 136 signatures in favour of the introduction of the light, while the owners or occupiers of 106 premises are prepared to use the light. As regards the means of introducing the light, the committee consider that it will be more effectively and more economically done by the Corporation than by a company. Comparing similar installations, it would appear that those laid down by companies are more expensive than those laid down by corporations. This, they say, can be accounted for by the fact that a company has not the same interest to consider economy as a responsible body, and a company expects a good percentage on their outlay while the plant remains in their hands, and a good price when it passes into the hands of a corporation. A corporation is also able to borrow at a low rate of interest, and will therefore be able to sell the light when first produced as cheap as a company, and will much sooner be in a position to reduce the price than if the light was installed by a company. The question of the disposal of the town's refuse is a point of increasing difficulty, and the committee have considered the advisability of disposing of the refuse by means of a destructor, and utilising the destructor so far as possible for the purpose of generating electricity. They find that there has been a great improvement in refuse destructors recently, and that within the last three years 52 combined refuse and electric installations have been laid down in England, while similar installations have lately been completed in Ayr and Port Glasgow with satisfactory results. A few days ago there appeared in the newspapers the description of an installation proposed for Dunfermline. Three systems were there considered—one where the electric power was to be purchased from a company at 1½d. per Board of Trade unit; another where power was to be raised from coal; and a third where a refuse destructor was to be used. The expert called in recommended that the system with the refuse destructor should be adopted. In estimating the value of the Elgin refuse as a power producer, the committee find from statements given by the manufacturers of refuse destructors and from the reports of sanitary inspectors of the towns where destructors have been erected, that over 35 Board of Trade units can be raised per ton of refuse destroyed. In Elgin there are over 10 tons of refuse per day to be disposed of, which at 35 units per ton would give 350 units per day, or 127,750 units per year. Allowing for one-third being lost in storing and transit, and the remaining 85,160 units being sold at 6d. per unit, £2 129 a year would be realised. Taking this calculation in another and perhaps a better way, it would take in Elgin ½d. worth of coal to generate one unit of electricity, and to produce 127,750 units would cost £266. 2s. 11d. Assuming that the cost of a destructor is £3,200, 6½ per cent., or £208, would be required to pay interest and sinking fund, and for this sum of £208, power worth £266 would be obtained, while £100 a year would be saved in the cartage of the refuse. The committee consider that these estimates are quite safe, and are proved by the fact that many towns are generating electricity from refuse where coal is much cheaper than here, and where gas is selling at from 2s to 3s. per 1,000 cubic feet. There are the following special and peculiar reasons why a destructor would be used to advantage in Elgin—viz.: the high price of coal, the amount paid for the carting of the refuse, the more effective disposal of the refuse, and the fact that wherever it is carted it still remains a nuisance. The committee, therefore, recommend that electric light be introduced into Elgin. Consideration of the report has been deferred.

**St. Andrews.**—The Electric Supply Corporation, of which Mr. K. A. Scott-Moncrieff is chief engineer and general manager, have nearly completed their work, and it is anticipated that current will be available within a few weeks. The station in Southfield has been erected by Messrs. Topping, Edinburgh. The contract for the equipment has been in the hands of Messrs. Crompton and Co., Limited. A detailed description just appeared in the *Dundee Advertiser* as follows: "Entering from the east side, there are the offices to the right, while to the left is a storeroom. The entrance passage leads into the engine and dynamo room, where there are three sets of engines and dynamos, and a spiral stair enters into the battery-room. Leading off the engine-room is the boiler-house, adjoining which is what is known as the pump-room. The boilers, which are two in number, are of Babcock and Wilcox patent water-tube marine type, each having a total heating surface of 1,443 square feet. Each boiler is fitted with a Babcock and Wilcock superheater having a heating surface of 332 square feet. They are capable of evaporating 6,000lb. of water per hour from hot feed water, and the superheaters are capable of imparting from 120deg. to 150deg. F. of superheat to the steam. The boilers and superheaters are made for a working pressure of 180lb. per square inch, and an isolating valve has been fitted to each boiler. Each boiler is also provided with a Babcock and Wilcox patent chain-grate mechanical stoker, which is specially adapted for quick steaming. There are two steel chimneys, each 3ft. in diameter and 80ft. in height. In the boiler-room is also a Webster vacuum feed-water heater capable of dealing with 1,200 gallons of feed water per hour, the water being heated with the exhaust steam from the engines. Erected on the roof over the open store is a Doulton water softener capable of softening from 100 to 800 gallons per hour. In the pump-room are three electrically-driven feed pumps, each pump being capable of delivering 600 gallons per hour against a pressure of 180lb., and over the pump-room is a cast-iron feed-water tank with a capacity of 8,000 gallons. There are three dynamos and engines. One is a Crompton-Rosvell steam dynamo, the engine being of the two-crank compound (enclosed) constant thrust type, coupled direct to a Crompton bipolar shunt-wound dynamo. The engine is capable of giving 75 b.h.p. with 180lb. steam pressure, non-condensing, when running at a speed of 560 revolutions per minute, and with the steam superheated to 479deg. F. The dynamo has an output of 104 amperes at 450 to 480 volts. The other two are Crompton-Bellias dynamos, the engines being of the two-crank, compound, enclosed, self-lubricating type, made by Messrs. Bellas and Morcom, Limited, Birmingham, coupled to Crompton multipolar shunt wound dynamos. These two engines are capable of giving 170 b.h.p with 180lb. steam pressure, non-condensing, and run at 450 revolutions per minute, with the steam superheated at about 479deg. F. The dynamos are wound for an output of 250 amperes at 450 to 480 volts. The motor-booster set consists of three multipolar machines, all coupled direct and mounted on one common bedplate, each of the booster dynamos being capable of giving 110 amperes at any voltage from 0 to 80 at a speed of 1,150 revolutions per minute. The motor is wound for coupling on to the 450 to 480 volt circuit. The balance set consists of two multipolar machines directly coupled together, and are capable of dealing with an out-of-balance current of 60 amperes with a voltage on either side of the three-wire system varying from 225 to 240 volts. The battery consists of 230 cells, divided into two equal parts, 115 cells serving each side of the system. The battery has a capacity of 400 ampere-hours. In the engine room is a five-ton overhead hand travelling crane. The switchboard consists of enamelled slate panels mounted on an iron frame, and contains all the usual fittings and instruments for dealing with the three dynamos, balancer, boosters, and battery, and two or three feeders as required. The wiring of the building has been carried out by Messrs. Chancellor and Peterkin, Edinburgh, and the street mains have been laid by the Callender's Cable and Construction Company, Limited, London, and Erith, Kent. The plant at the station has been fitted up under the direction of Mr. R. M. M'Leay, Messrs. Crompton and Co.'s representative, while the whole of the operations have been supervised by Mr. B. G. Drummond, the resident engineer of the Electric Supply Corporation."

## PROVISIONAL PATENTS, 1905.

APRIL 19.

**8326. An improved switch for electric lighting circuits.** Joseph Hutton, 37, Huntriss-row, Scarborough, Yorks.

**8330. Improvement in automatic switches and circuit breakers.** James Henry Ward, Albert Alexander Godstone, Meyer Hart Godstone, and Harry Scott Nowell, Dutton-street Strang-ways, Manchester.

**8344. Improvements in and in the manufacture of metallic frictional blocks, such as brake-blocks, electrical collector slippers, and the like.** Thomas Ashmore and Phelam McCullough, 10 St. George's-crescent, Liverpool.

**8357. An improved way of administering electricity for medical purposes and apparatus used in connection with same.** William Davenport, 147, Stamford-street, London.

**8391. Improvements in electricity meters.** Joseph Devonport Finney Andrews, 2, Park-avenue, East Sheen, London

**8394 Improvements in or relating to electric motors.** Dr. Max Corsepius, 24, Southampton-buildings, Chancery-lane, London.

**8409. Improvements in selecting devices applicable to party-line telephone systems and the like.** Paul Arnheim, 322, High Holborn, London.

**8410. Improvements relating to electrically-operated selecting and switching devices applicable to party-line telephone and telegraph systems.** Paul Arnheim, 322, High Holborn, London.

**8411. Improvements in and relating to central-battery telephone systems.** Paul Arnheim, 322, High Holborn, London.

APRIL 20.

**8443. Improvements in connection with trolleys of electric tramcars and the like.** Horace Halstead, Archer Johnson, and Samuel Winn, Tower-chambers, Halifax.

**8444. An improved "cut-out" for electric lamps and holders and other purposes.** Archibald Walker and John Manton Walker, Olivet House, Old Conduit-street, Gloucester.

**8511 Improved method of and means for "tuning" Hertzian wave receivers to particular transmitters.** Christian Hülsmeyer, 72, Cannon-street, London. (Complete specification.)

**8541. Improvements in the regulation of electric circuits subject to rapidly fluctuating loads.** Edmund Scott Gustave Rees, Charles Hodgson Iles, and William Armistead, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

**8563 Improvements in electric arc lamps with multiple carbons.** William Gamble, 28, New Bridge-street, London.

**8567. Improvements in and relating to systems of electric distribution employing mercury vapour lamps or the like.** The British Thomson-Houston Company, Limited, 83 Cannon-street, London (The General Electric Company, United States) (Complete specification.)

**8568. Improvements in and relating to machines for use in the manufacture of incandescent electric lamps.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

**8569. Improvements in and relating to dynamo-electric machines.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

**8570. Improvements in and relating to the regulation of the output of electric generators driven at varying speeds** The British Thomson-Houston Company, Limited, Frank Holden, and Alexander Stanley Garfield, 83, Cannon-street, London.

**8571 Improvements relating to systems of electric transmission.** John Dunlop Hilliard, jun., 83, Cannon-street, London. (Date applied for under Patents Act, 1901, April 20, 1904, being date of application in United States). (Complete specification.)

APRIL 22.

**8613. Apparatus for electrical drying of insulation of cables.** George Hinde Nisbett, 65, Chancery-lane, London. (Complete specification.)

**8615. Improvements in electric switches.** Walter F. Jones, Donald G. Macmillan, and Gustave J. Neybergh, 65, Chancery-lane, London. (Date applied for under Patents Act, 1901, Jan. 12, 1905, being date of application in Belgium.) (Complete specification.)

**8631. An improved dry battery.** Fredrick Weatherill, 11, Lowden-road, Herne Hill, London.

**8652. Improvements in plug-boxes and the like for the connection of electric conductors to the main supply cables.** George Arthur Kirk and the Corlett Electrical Engineering Company, Limited, 6, Lord-street, Liverpool.

**8659. Means for protecting electric telegraph lines against the influencing action of alternating-current lines situated in the neighbourhood thereof.** Siemens Bros. and Co., Limited, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Siemens-Schuckertwerke G. m. b. H., Germany.) (Complete specification.)

**8663. Improvements in and relating to electro-mechanical block signalling systems for railways and the like.** Attilio Beer, 7, Southampton-buildings, Chancery-lane, London. (Complete specification.)

APRIL 25.

**8704. Improvements in means for supporting telephone receivers.** Frank Wesley St. John, 52, Chancery-lane, London. (Complete specification.)

**8711. Improvements relating to the distribution of electric energy to apparatus capable of being operated by direct and also by alternating currents.** Benjamin Garver Lamme, the Westinghouse Patent Bureau, Westinghouse-building, Norfolk-street, Strand, London. (Date applied for under Patents Act, 1901, May 3, 1904, being date of application in United States.) (Complete specification.)

**8721. Improvements in processes of preparing nitrogen-oxygen compounds by means of electricity.** Westdeutsche Thomasphosphat-Werke G. m. b. H., 322, High Holborn, London. (Date applied for under Patents Act, 1901, April 7, 1905, being date of application in Germany.) Complete specification.)

**8728. An improved trolley retractor.** Henry M. Love, 1, Queen Victoria-street, London. (Complete specification.)

**8732. Improvements in systems and means for laying electrical wires in conduits.** Guy Moore Gest, 40, Chancery-lane, London. (Complete specification.)

APRIL 26.

**8821a. Telephonograph.** Joseph Skwirsky, 35, Newman-street, Oxford-street, London. (Date applied for under Patents Rule 9, March 20, 1905.)

**8759. Electric distant gas-lighting device.** Adolf Mautz, Blumenstrasse 25, Stuttgart, Germany. (Date applied for under Patents Act, 1901, April 27, 1904, being date of application in Germany.) (Complete specification.)

**8765. Electrical connection for cables to sparking clubs of internal-combustion engines or for other purposes.** Luther Padwick and James McKechnie, care of Vickers, Sons, and Maxim, Limited, Barrow-in-Furness, Lancs.

**8786. Improvements in electric controllers and starting switches.** Daniel Adamson and John Brentnall Duckitt, 17, St. Ann's-square, Manchester.

**8789. Method for safeguarding electric unipolar cells.** Robert Grieson, 32, Waisenhauster, Dresden, Germany. (Complete specification.)

**8822. Improvements in the regulation of electric circuits subject to rapidly fluctuating loads.** Edmund Scott Gustave Rees, Charles Hodgson Isles, and William Armistead, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

**8828. Improvements in electric arc lamps.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

**8829. Improvements in electric arc lamps.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

**8838. Improvements in and relating to apparatus for telegraphic purposes.** Joseph Theodor Szek, 22, Southampton-buildings, Chancery-lane, London.

APRIL 27.

**6959a/04. Improvements in carbons and in the manufacture thereof.** Howard Coppuck Lewis, 83, Cannon-street, London. (The General Electric Company, United States.) (Date applied for under Patents Rule 9, March 22, 1904.)

**7843. Improvements in lifeguards for electrically-driven tramcars, trains, and other vehicles supplied on the overhead or trolley system.** W. T. Skelding and Co., Limited, and Frederic Charles Geary, 189, Wolverhampton-street, Dudley.

**8846. An improved electrical collector trolley-head.** Robert Baron, 10, St. George's-crescent, Liverpool.

**8847. Improvements in apparatus for controlling poles and ropes of electric tramway vehicles.** William James Bowden and James William Cronkshaw, 6, Bank street, Manchester.

**8880. Improvements in wireless telegraph system.** Harry Shoemaker, 7, Southampton-buildings, Chancery-lane, London. (Complete specification.)

**8891. Improvements in and relating to filaments for electric and other lamps.** Ernest Léon Frenot, 7, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents Act, 1901, May 7, 1904, being date of application in Belgium.) (Complete specification.)

**8906. Improvements relating to the distribution of electrical energy.** Ernest Rowland Hill, Westinghouse Patent Bureau, Westinghouse-building, Norfolk-street, Strand, London.

**8913. An improved controlling system for electric railways.** Thorsten von Zweigbergk, 18, Southampton-buildings, Chancery-lane, London. (Complete specification.)

**8921. Improvements in electric railway systems.** George Lowe Campbell and William Melvirne Stephens, 4, South street, Finsbury, London. (Complete specification.)

**8931. Improvements relating to points or switches for electric tramways working upon the slot conduit system.** Albert Newman Connett, 322, High Holborn, London. (Complete specification.)

Digitized by Google

**8967. Improvements in systems of electrical distribution.** Paul Martyn Lincoln, Westinghouse Patent Bureau, Westinghouse - building, Norfolk-street, Strand, London. (Date applied for under Patents Act, 1901, May 3, 1904, being date of application in United States.) (Complete specification )

APRIL 28.

**8968. An improvement in adjustable brackets for electric lamps.** Arthur John Whitcombe and Maxwell Williams, 31, Harmer-street, Gravesend.

**8972. Improvements in systems of electrical distribution of direct currents by means of vapour rectifiers.** Peter Cooper Hewitt, the Westinghouse Patent Bureau, Westinghouse - building, Norfolk-street, Strand, London. (Date applied for under Patents Act, 1901 May 13, 1904, being date of application in United States.) (Complete specification.)

**8973. Improvements in vapour electric apparatus.** Peter Cooper Hewitt, the Westinghouse Patent Bureau, Westinghouse - building, Norfolk-street, Strand, London. (Date applied for under Patents Act, 1901, May 13, 1904, being date of application in United States.) (Complete specification.)

**8975. Improvements in automatic telephone exchange systems.** Bernhard Kugelmann, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents Act, 1901, April 29, 1904, being date of application in Germany.) (Complete specification.)

**8991. An improved process for insulating electric wires and cables.** La Compagnie Française de l'Amainte du Cap, 7, Southampton - buildings, Chancery - lane, London. (Date applied for under Patents Act, 1901, May 10, 1904, being date of application in France.) (Complete specification.)

**8994. Improvements in electric switches or connectors.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States )

**8996. Improvements in electric arc lamps.** Edwin Rudolph Grote and Milton Victor Ely, trading as Foster and Co., Palace-chambers, Westminster, London.

APRIL 29.

**9057. A new or improved electric water-heating apparatus or radiator.** Leonora Binko, trading as the Electric Heating Company, 9, Warwick-court, Gray's-inn, London.

**9064. Improvements in electric switches or circuit breakers.** The British Thomson-Houston Company, Limited, and Edwin Joseph Murphy, 83, Cannon-street, London.

## COMPLETE SPECIFICATIONS ACCEPTED.

*To be published May 18.*

1904.

**7044. Electro-capillary apparatus.** Armstrong and Orling.

**8910. Push-buttons for closing electrical circuits.** Klein.

**10800. Electric transformers.** Berry.

**10878. Devices for protecting alternating-current electric apparatus.** British Thomson-Houston Company, Limited. (General Electric Company.)

**12737. Electrical motor and speed-control arrangements therefor.** Bentley.

**13543. Electrical switches.** Lundberg and Lundberg.

**14460. Reduction of displacement of phase in electric current circuits.** Johnson. (Badische Anilin und Soda Fabrik.)

**27900. Secondary batteries.** Gardiner.

**28980. Joint-arm applicable for supporting electric lamps.** Nieriker. (Date applied for under International Convention, Oct. 8, 1904.)

1905.

**789. Electric heating of electrically-propelled vehicles.** Union Elektricitäts-Ges. (Date applied for under International Convention, Jan. 16, 1904.)

**923. Electrical measuring instruments.** Conrad. (Date applied for under International Convention, Jan. 20, 1904.)

**3409. Arrangement of multiple switchboards for telephone exchanges.** Siemens Bros. and Co., Limited. (Siemens und Halske Akt.-Ges.)

**3510. Devices for preventing the overcharging of electric cables.** Land und Seekabelwerke Akt.-Ges. (Date applied for under International Convention, March 31, 1904.)

## NOTES.

**Electrical Engineers (R.E.V.).**—The corps held a successful Bohemian concert—the last of the season—at the Caxton Hall on Saturday last, Colonel Crompton, C.B., the commanding officer, occupying the chair.

**The Institution.**—The meeting last week at the Society of Arts was occupied with Mr. A. M. Taylor's paper on "Stand-by Charges and Motor-Load Developments," a report of the discussion on which will appear in our next issue.

**New Marconi Station.**—It is reported that arrangements are in progress for the establishment of a wireless telegraph station at Machrihanish (Argyll) for the transmission of messages by the Marconi system. Ground has been acquired in the vicinity of Losset, but the site has not been finally decided upon. The tower for the dispatch and reception of messages will have an elevation of 400ft.

**Wireless Telegraphy on Lightships.**—Replying to a question in the House by Major Seely as to whether the work of installing wireless telegraphy on the six lightships for life-saving purposes had now been commenced, Mr. Bonar Law, secretary to the Board of Trade, replied that the agreement with the Marconi Company had been finally settled, and the work of installation was being put in hand forthwith.

**Faraday House.**—As a result of the recent scholarship examination the following awards are recommended: to Edward Stanton Ritter, of Cheltenham College, a Maxwell scholarship of 50 guineas, tenable for two years; to Louis Dudley Hooper, of Bournemouth School, and James Ardern Taylor, of Wellingborough Grammar School, exhibitions value 30 guineas, tenable for two years. The following candidates, who distinguished themselves in the above examination, have been awarded special prizes of 20 guineas each: Arthur Lionel Ballard, of Dunheved College; Edgar James Barnes, of Bournemouth School.

**X-Rays.**—A feature of special interest on the concluding day of the Röntgen congress held at Berlin last week was the discussion upon the treatment of cancer by X-rays, as opposed to surgical methods. Prof. Lassar, the well-known authority on skin diseases, advocated the application of X-rays in cases of great suffering, adding that his experience was that they relieved pain. He contended that the rays were greatly superior to the knife for the removal of cancerous growths, and declared that the success achieved by the Röntgen treatment in gangrenous cancer formations was such as the boldest imagination did not dream of a few years ago. In a hundred such cases he had only had three failures.

**Parcel Traffic on Tramways.**—The Manchester Corporation, which recently instituted an elaborate tramways parcels express, have had proceedings instituted against them by Messrs. Sutton and Co., a firm of local carriers, who seek an injunction to restrain the Corporation from conveying, collecting, and delivering goods or parcels by means of road vans, hand carts, or messengers, and acting as general carriers or railway agents. The plaintiffs also seek a declaration that it is unlawful for the Corporation to expend any moneys of the city for such purposes, or to use any buildings, plant, apparatus, or servants belonging to the tramways undertaking otherwise than for the working and using of the tramways. The Corporation will defend the action.

**New Publications.**—We have received a copy of the *Wisconsin Engineer* dated April, which contains articles on "Central-Station Engineering," by Mr. C. H. Williams; "The Public Water Supplies of Wisconsin," by Mr. W. C. Kirchoffer; "The Relations of the Engineer to the Telephone Business," by Mr. A. S. Hibbard; "Desirable Product from the Teacher of Mathematics," by Mr. D. C. Jackson," and "The Physical Properties of Wisconsin Railways." The *Transactions* of the North-East Coast Institution of Engineers and Shipbuilders, dated April, contain Mr. W. R. Cummins's reply to the discussion on "A Comparison of Vertical and Horizontal Tubes in Watertube Boilers," and a paper on "Petrol Motorcars," by Mr. Frank Little, with the discussion thereon.

**Optical Convention.**—We learn from Mr. F. J. Selby, hon. secretary of the Optical Convention, which opens on May 30, that preparations are now approaching completion. In addition to the papers previously announced, a contribution is promised from Lord Rayleigh on "The Polishing of Glass Surfaces," and Prof. Schuster will read a paper on "Spectroscopic Optics." The demonstrations of special apparatus arranged for the afternoons include the following: multiple colour illumination for microscopic objects, by Mr. J. Rheinberg; diffraction apparatus, by Mr. J. Rheinberg; quartz crystals, by Mr. J. Woodward; spectroscopes, by Mr. F. Twyman; and interferometer, by Mr. H Stansfield. The convention has the support of the Mercers', Goldsmiths' and Clothworkers' Companies. The convention is to be held at the Northampton Institute.

**Electrical Contractors' Association.**—The Leeds branch of the Electrical Contractors' Association held their annual meeting on Saturday at the Great Northern Victoria Hotel, Bradford. There was a good attendance of members. The report and balance-sheet were adopted, and the officers for the ensuing year elected. Mr. W. P. Steinthal was elected chairman and Mr. J. H Taylor (Huddersfield) vice-chairman. Mr. E. C. Wallis, who had rendered valuable service as secretary, consented to retain his office for another 12 months. Following the meeting a dinner was held, at which the majority of the members were present, and several guests, amongst the latter being Mr. Rolles and Mr. Allsopp, of the Bradford Corporation electricity department, and Mr. E T. Steinthal, a member of the Central Board of the association. The dinner was succeeded by a smoking concert.

**London Traffic Commission.**—The Royal Commission on London Traffic held sittings in private last week at the Westminster Palace Hotel. The Commissioners are stated to have practically concluded the consideration of their draft report, but apparently they had not finished taking evidence. The witnesses on the first day were Mr. Daniel Duff, manager of the London Road-Car Company, on behalf of omnibus proprietors in London; Mr. A. T. Salisbury Jones, chairman of the London Motor Omnibus Company, Limited; and Mr. A. Campbell Swinton, chairman of the London and District Motor 'Bus Company. Their evidence was chiefly directed to the results that have attended the introduction of motor omnibuses into the streets of the Metropolis in respect of traffic, cost of operation, renewals, repairs, and depreciation. The witnesses on Friday were Mr. C. R. Bellamy, general manager of the Liverpool Corporation tramways, and Mr. J. M. McElroy, general manager of the Manchester Corporation tramways, who attended to supply the Commission with details of tramways working in those cities. It is stated that this really concludes the evidence, and it is anticipated that the report will be presented to Parliament by Whitsuntide.

**Single-Phase Elevator.**—At the fifth annual convention of the Iowa Electrical Association, Mr. L. Sparrow, of St. Louis, read a short paper on the Wagner single-phase elevator and hoisting motor, of which an abstract appears in the *Electrical World* of New York. This motor, which has

Digitized by Google

recently been put on the market, behaves, as regards current consumption, very similarly to a shunt direct-current motor, giving a torque in starting in direct proportion to the current used. In elevator service the excess torque and current over the normal in starting is not less than 50 per cent. This excess current, however, falls rapidly as the elevator is accelerated. The polyphase induction elevator motor may require as high as 500 per cent. more than full-load current in starting. This motor makes it possible to give with a single-phase distribution all the kinds of service given by direct current at the present time, and more than are usually feasible with polyphase motors. The new Wagner motor is stated to have a power factor of at least 70 per cent. in starting and 80 to 85 per cent. when running at full speed. The motor in elevator service can be used as an electric brake running as an induction generator if the armature is rotated at a speed in excess of synchronism. The motor is capable of 40 per cent. speed variation, with constant speed at whatever point it may be adjusted, thus making it applicable to ventilating fans and machine shop tool service.

**Wireless Telegraphy.**—Statements in the Press record that another "important discovery" has been made in this field, the achievement being credited to Father Joseph Murgas, pastor of the Catholic church at Wilkesbarre, Pennsylvania, who is stated to have been making experiments for the last seven years. He is reported to have demonstrated that "by conveying musical tones instead of the Morse code he can make communications with almost certain success." For the purpose of his experiments he uses a pole 200ft. high in his rectory yard, and he is stated to have been in constant communication with Scranton, 18 miles away. Operating with two tones only, Father Murgas is stated to exceed the speed obtained by any other system, and he has now almost perfected a complete tone alphabet, the speed of which is limited only by the capacity of the receiver to read the messages, which reminds one of a more familiar system. We are further told that the present cost of this system is not more than one-third the cost of other systems. The report concludes with the information that the transmitting and receiving instruments are the most simple yet devised, and the initial cost is small, because either earth or air current can be used singly or combined. This sounds like progress; but, unfortunately, these admirable systems have a habit of vanishing from the public ken with the same meteoric suddenness as that with which they are heralded.

**Telephone Call Offices.**—The report of Dr. Collingbridge, medical officer of health for the City, should go far to allay the apprehensions of those who feared that the instruments at the public call offices were open to the gravest hygienic objections, it having been suggested that there was especial danger of tuberculosis and diphtheria being communicated by one user to another. With the sanction of the National Telephone Company a number of call offices were selected, the mouthpieces removed, placed in sterilised bottles, and submitted to Dr. Klein for bacteriological examination. As the result of experiments on two guinea-pigs, it was found that the mouthpieces contained no tubercle or diphtheria germs. In all 12 mouthpieces were thus treated. The result was exceedingly satisfactory, as it showed that in none of the mouthpieces were any tubercle bacilli present. The conclusion, therefore, was that there is no real risk in the use of the telephone at public call offices, and that the alarm that had been raised had no foundation in fact. The only precaution advisable was the obvious common-sense one of keeping the mouthpieces clean. The medical officer had for some time been in communication with the Telephone Company with regard to the condition and ventilation of their boxes. They had undertaken to improve the ventilation and to line the boxes with an improved material which would allow of their being thoroughly cleansed, thus doing away with the accumulation of dust.

**Niagara.**—Both Houses of the American Legislature adjourned last week without coming to a decision upon the Niagara Power Bill, which is consequently hung up indefinitely. This result is apparently due to the publicity given to the corrupt practices of the promoters' agents, the *New York World* estimating the amount spent in "persuading legislators to vote for the measure" at £30,000, whilst the *New York Sun* stated that it would be passed at the last moment "if lobbying could buy the needed votes." The feeling of opposition on the part of the public was, however, very strong, and was supported by the Governor of New York State, who apparently wields considerable power in this matter. The promoters were, therefore, unable to force the Bill through. This continuation of the bribery perpetrated in the earlier history of the American side of the Falls cannot well be too strongly deprecated, but at the same time we scarcely think that æsthetic considerations should be allowed to outweigh those of a utilitarian nature. Although the powers proposed to be taken by the promoters are of an extensive character, they are scarcely likely to avail themselves of them to the full unless there is a corresponding market, in which case economic considerations would probably justify such a course. There is still the question of payment for the water thus taken to generate energy. It is notorious that as the result of bribes, huge concessions were given away in connection with previous American schemes for utilising the Falls, instead of a reasonable charge being made, as is done by the Dominion Government. We do not know the precise terms of the present Bill, but a tax, at once adequate and reasonable, is only what the circumstances of the case demand and the value of such a concession merits.

**Local Sections.**—Elsewhere in this issue will be found an interesting suggestion for the extension of the good which the local sections of the Institution of Electrical Engineers have already performed. Until these sections were organised it was, as a rule, only the heads of firms who were able to attend with any degree of regularity the meetings of the parent Institution. Their presence at the London meetings rendered the same more interesting than they have been during the past year or two. With the formation of the local sections the number of papers read and discussed each year has increased, but what is much more important is that the number of electrical engineers who have been able to take part in the discussions or to listen to them is very much larger. The social intercourse after the meeting between the engineers engaged in the local firms is also a most valuable feature of the meeting. It is now suggested by a contributor that these local sections should undertake the distribution of standard technical literature to the members. This could be organised much in the same way as a lending library, and the membership fee should be made to cover all but the postage expenses. The junior members of the profession naturally find it impossible to buy for themselves a complete set of standard works on electrical engineering, or to subscribe to even one technical journal from each country interested in electrical manufacturing. In this respect the London members have the advantage of the library in Victoria-street, and the proposal to render the volumes in this library accessible to country members needs careful consideration. In our opinion the value of a library is largely

Digitized by Google

reduced if once books are lent out. Thus, while our correspondent's suggestion is a most valuable one, we think the books which should be circulated should be duplicate copies of standard works specially obtained for the purpose. Further, in connection with every local section there should be arranged a room in which, during certain nights in the week, the technical journals from foreign countries, as well as the English ones, could be read by members. This room would also afford a meeting place for electrical engineers, and would extend the opportunities for that mutual assistance which members can render to each other.

**Engineering Standards Committee.**—We have received reports Nos. 20 and 21, which respectively deal with "British standard screw threads" and "British standard pipe threads." The committee recommend that the Whitworth form of thread be adopted on all screws of ¼in. diameter and above, having either Whitworth or British standard fine pitches. The committee also recommend that all screw threads made in accordance with the sizes given in Table I. be known as "British standard Whitworth screw threads (B.S.W.)," those in Table II. as "British standard fine screw threads (B.S.F.)," and those in Table III. as "British Association screw threads (B.A)." The retention of the pitches originally devised by Sir Joseph Whitworth is advocated. To meet the wide-spread desire for a series of finer pitches to supplement those of Sir Joseph Whitworth, the committee have prepared a table of fine pitches of ¼in. to 6in. diameter. For odd sizes the committee recommend the adoption of the pitch and depth of thread for the size immediately preceding the required one. The pitches given in Table II. for sizes up to and including screw threads of 1in. diameter are based on the formula $P = \frac{\sqrt[3]{d^2}}{10}$, P equalling the pitch of thread in inches and $d$ the full diameter of thread in inches. For those sizes above 1in. diameter up to and including screw threads of 6in. diameter the pitches in Table II. are based on the formula $P = \frac{\sqrt[3]{d^5}}{10}$. The Committee on Screw Threads and Limit Gauges are at present engaged how best to secure satisfactory interchangeability between male and female screws. Report No. 21 contains recommendations regarding the form of pipe threads, a definition of the Whitworth thread, sizes of tubes, couplers, etc. The committee also recommend that a complete set of standard male screw gauges be made in accordance with the specified tables, and that they be deposited with some recognised authority, such as the Board of Trade or the National Physical Laboratory, for reference. These two reports are published at 2s. 6d. each, and can be obtained from the offices of the committee or from any bookseller.

**Association of Tramway and Light Railway Officials.**—The ninth general meeting of this association was held at Bristol last week under the presidency of Mr. H. England, manager of the Wakefield Light Railways Company. The members present hailed from London, Birmingham, Norwich, Darlington, Brierley Hill, Wolverhampton, Rossendale, Worcester, Wakefield, etc. Mr. Charles Challenger, the traffic manager of the Bristol Tramways Company, in welcoming the members of the association on behalf of the directors of the company, alluded to the great expansion of the Bristol system, which during last year carried the population almost three times each week. The route length to-day was about 30 miles, and it was not the company's fault that there was not double that length of route. Bristol was amongst the first two or three tramway companies in this country to operate horse cars, and was the first to run electric cars under the Board of Trade rules. Referring to the great engineering work done by Sir George White and his brother, Mr. Samuel White, the speaker said that their achievements in Bristol alone would have placed them in the front rank of electric tramway organisers, but the marks of their genius in this respect had been impressed upon many towns in this kingdom. The London United Tramways, on account of the formidable obstacles of various kinds to be overcome, stood out as a monument to their and Mr. Clifton Robinson's genius, tact, and enterprise. In conclusion, he outlined the provision made by the company for old employés, which, starting with a provident fund, had now developed into a pension scheme, whereby an annuity was secured to employés at the age of 65 without any contribution from them. Mr. Sydney E. Smith, the assistant traffic manager, also read a paper on the system, in which he reviewed its technical aspects. Mr. Conaty offered congratulations on the pension fund, which was a step in the right direction, though he was afraid that all tramway concerns could not afford it. New members having been elected and the report and accounts adopted, the president and Mr. Conaty were elected to represent the association at a conference upon the desirability of amalgamating the Municipal Tramways Association, the Tramways and Light Railways Association, and this association.

**Electricity on a German Warship.**—The liner "Preussen," which was launched from the Vulkan shipyards in Stettin, Germany, at the end of 1903, and which at the present moment is at anchor at Swinemünde, is to be put into service and will be attached to the Baltic marine station this month. It has three screws, and is about 400ft. in length, 70ft. in breadth, and 25ft. in draught, with a displacement of 13,200 tons. It develops a speed of 18 knots, the capacity of her engines being 16,000 h.p. The vessel is fitted with a belt armour of 225mm. and an armoured deck of 75mm. thickness. Her artillery equipment comprises four quick-charging guns of 12in. gauge, 14 7in. quick-charging guns, and 12 of 3½in. gauge, 12 1½in. machine guns, and eight machine rifles, in addition to six torpedo-launching tubes. Her crew consists of 697 men. All the internal rooms as well as the upper deck are lighted by electric glow lamps. For use in connection with the scouting service in action or, generally speaking, whenever the enemy is close by, as also for signalling to a distance, there are used four large projectors of 61 million normal candle-power each. Electromotors are being used extensively for such purposes as conveying ammunition from the ammunition stores to the guns, moving the rotating armoured gun-turrets, handling coal, lowering or hauling the large boats, operating the machine tools and refrigerating plant, as well as for driving the numerous fans of different sizes, which are installed in all the compartments of the ship. The whole of the apparatus used for the transmission of orders from one part of the ship to another, as well as for mutual communication between different places—*i.e.*, the telegraphs controlling the rudder, engines, boilers, artillery, and torpedo rooms—the optical signalling apparatus for the transmission of orders and intelligence from ship to ship or from land to ship, the telephone and alarm plant, the medical outfit of the infirmaries, and instruments for indicating the depth, etc., are operated by electricity. The whole of the above machinery and apparatus has been constructed by the Siemens-Schuckert Works, which syndicate also installed the two central stations supplying the current for their operation as well as the one required for the "Telefunken" wireless telegraph apparatus. These central stations contain an aggregate of four turbo-dynamos of

Digitized by Google

65 kw. each in addition to a storage battery, intended to serve as reserve.

**Personal.**—Mr. W. A. Chamen, late chief engineer to the Glasgow Corporation electricity department, was entertained to dinner at the Grosvenor Restaurant, Glasgow, on the evening of Thursday, the 4th inst., by members of the electrical profession in the neighbourhood and the staff of the electricity department. Ex-Bailie D. M. Stevenson presided over a large company, covers being set for considerably over 200. Several scientific bodies, including the Institution of Electrical Engineers, were represented. The Chairman, in proposing the toast of the guest, recalled the early history of the electricity undertaking, which was originally a very small affair under the wing of the gas department. Mr. Chamen promptly realised the desirability of forming the electricity undertaking into a distinct department, and since the separation had been accomplished it had developed by leaps and bounds. Although their late chief engineer did come from south of the Tweed, the credentials with which he came gained the confidence of the committee, and he immediately justified this confidence by formulating a scheme for a large power station at Port Dundas, another power station being opened shortly afterwards at St. Andrew's Cross. The result was that the annual output had increased from some 26,000 to 17,000,000 units, and the revenue from £3C,000 to £180,000. He (the speaker) had never known an official who managed to get along as Mr. Chamen had done—he pleased the contractors, the Corporation, and the consumers, and in his presence difficulties disappeared. Mr. Thomas Wright, chairman of the Electrical Contractors' Association, supported the toast, which was received with acclamation. Mr. Chamen, in returning thanks, said that the friendly relations which had always existed between him and the staff were due to a very simple circumstance. He explained, amid laughter, that whenever any problem arose he had called in his assistants, who all expressed their ideas, and then he said what he thought should be done, which was done, and that was all. It had given him the greatest pleasure to see that Mr. Lackie was to take his place as chief engineer, with Mr. Page as chief assistant. He might add that a great deal of rubbish had been talked about Englishmen not being liked in Scotland; his experience had been that the alleged prejudice was a myth.

**Electrification of Trunk Lines.**—An illustrated lecture on the "Application of Electricity to Heavy-Freight and Trunk-Line Railways" was recently delivered by Mr. J. H. Hallberg before the Electrical Engineering Society of Columbia, and an account of same appears in the *Electrical Review* of New York. The lecturer described in detail all electric systems which have been proposed and tried for trunk-line service, and a number of lantern slides illustrating the 15,000-volt single-phase railway developments carried on by the Oerlikon Electric Company, of Zürich, Switzerland, under the direction of Mr. Emil Huber, were the subject of an interesting description and discussion. After describing the Oerlikon system, the electrical equipment for the New York Central Railroad (now being manufactured by the General Electric Company), and the Siemens and Halske locomotive used for the high-speed electric railway tests between Marienfelde and Zossen, an interesting discussion ensued upon the single-phase to polyphase electric railway system lately invented by the lecturer. The important feature of this system is that it is possible to build very powerful locomotives which can be operated with only one contact wire delivering high-voltage single-phase current to the locomotive. The current is converted on the locomotive by means of a motor-generator set into polyphase currents suitable for the polyphase induction motors, which are mounted on the driving axles. As all generating and transforming apparatus are of the alternating-current type, no commutators are required, and the use of induction motors on the locomotive eliminates altogether the use of commutators for any of the main generating or driving machines for this system. Subsequently the various forms of construction for overhead contact wires for high-speed trunk-line railways were considered, and the general opinion was that it would be preferable to make contact on the top of the contact wire, as suggested by Mr. Huber, of the Oerlikon Company, instead of using the ordinary catenary suspension, which makes it necessary to collect current from the underside of the contact wire. The lecturer agreed with Mr. C. O. Mailloux and Mr. Damon in that nothing less than 15,000 volts should be used for heavy trunk-line traction, and that the use of more than one wire for each track would be prohibitive. Mr. Hallberg also commented favourably upon Mr. Mailloux's suggestion to generate current at about 15,000 volts, which could be distributed directly to the contact wire wherever necessary, instead of generating current at a low voltage and then stepping up to a very high voltage for the transmission lines and again reducing the pressure at sub-stations for the contact wire. Where large amounts of power are generated, as for a large trunk-line railway system, it would perhaps be more economical to generate and distribute directly to the contact wire through high-potential transmission lines without the use of sub-stations.

**Grinding of High-Speed Commutators** — An article on this subject appears in the *Electrical World* of New York from the pen of Mr. O. H. Crossen. The author points out that an objection raised against the use of rotary converters on 60-cycle alternating-current systems is based on the troubles encountered at the commutator. While the design of the commutator for a low-voltage 25 cycle converter is comparatively free from difficulty, the problem becomes more complex with increase of either the frequency or the E.M.F. For very high frequencies and voltages the designer is forced to use an extremely large number of commutator segments, or to accept a high difference of potential between adjacent segments; to use very thin segments or to resort to high peripheral speeds. It is evident that any of these extremes would prove detrimental to the sparkless operation of the commutator, and with 60 cycle rotary converters for railway work a compromise design must be adopted, a large number of thin segments being used upon a commutator having a high peripheral speed. Even with a commutator of the best construction, sparkless performance will not be obtained unless the bearing surface of the mica and segments be kept perfectly true. Any slight roughness of the surface, due to difference in height of the mica and the segments, will cause under the brush a spark which will burn the segments and thus increase the roughness, so that the effect is cumulative. Continued operation of a roughened surface will soon result in the necessity for the use of a turning tool to prevent the sparking. The most common method for smoothing a commutator involves the frequent use of sand-paper. The author believes this method to be inadequate, since it merely postpones the trouble for a day or two at the most, and it causes the rapid wearing away of the commutator. Experience indicates that it is impossible to obtain good results from the use of sand-paper upon a commutator having a peripheral velocity as high as 4,600ft. per minute. Excellent results have been obtained, however, by using the brushes themselves for grinding the commutator. For this purpose the machine should be driven by some external means, as, for

Digitized by Google

example, by the small starting motor on its shaft, and its field circuit should be open, so that no E.M.F. is generated at the commutator. A thin film of light engine oil should then be applied to the commutator with a cloth. Within from three to five minutes the surface of the commutator will be ground smooth, due to the cutting of the brushes. The grinding being completed, the oil should be removed, and a little gasoline applied with a cloth to thoroughly clean the commutator and brushes. Care should be exercised to remove all oil from the underside of the brushes, for any oil which finds its way to the commutator during operation is liable to become carbonised and cause trouble. Mr. Crossen states that commutators may be kept in practically perfect condition if they are ground in this manner whenever sparking begins to appear. Some commutators will require this treatment after a run of 20 hours, but with others the process need not be so frequent.

**Rare Earths in Electric Illuminants.**—A paper was recently read before the Engineers' Society of Western Pennsylvania, by Mr. M. C. Beebe, upon "The Use of Rare Earths in Electric Illuminants." The author commenced by discussing the wide field for a filament that would supersede the carbon type in both arc and incandescent lamps, for though carbon is practically infusible, the temperature at which it operates in the incandescent lamp causes vaporisation. He then described the properties of the various rare earths, with special reference to a combination of zirconium and yttria earths. Experiments indicate that the yttria earths of the greatest atomic weight give the most satisfactory result in glowers. Further on Mr. Beebe dealt with the possibilities of self-starting filaments. Many oxides will conduct at room temperature. A mixture of iron and tin oxides, about 70 iron to 30 tin, will start without preliminary heating and withstands rather a high temperature. There are many other similar combinations, likewise other possibilities exist; such as carbides, silicides and borides, operated either in vacuum or gases. A Nernst glower may be made to conduct current at low temperatures by running it for a short time in a rarefied atmosphere containing a carbon gas. If to a globe in which a glower is operating in a good vacuum an amount of hydro-carbon gas is admitted sufficient to lower the vacuum even less than a millimetre, the potential difference across the terminals of the glower will decrease rather rapidly, and in the space of a few minutes, or even seconds, the glower will have become a conductor when cold; in other words, self-starting. The author then detailed an experiment in support of this theory. A glower was mounted in a glass bulb and in the axis of a carbon filament of a helical shape. The bulb was exhausted well and sealed off. The carbon filament was used four or five times to start the glower, alternating current being employed. After the glower had run a few hours it was noted that it was changing colour at its terminals. The discoloration gradually crept toward the centre, and after about 24 hours the glower could then be started without preliminary heating. Apparently, enough of the carbon filament was oxidised during the short time it was in use to give a slight quantity of free carbon monoxide in the bulb, the source of oxygen being the glower itself. It is uncertain whether this gas was effective in reducing some of the glower material to its metallic form, or whether a conducting carbide was formed by the action of the carbon gas upon the glower materials. The author prefers the former reason, because it is noticeable that the darkened portion at the negative end of direct-current glowers is of higher conductivity than the glower proper, and it seems quite likely that this deposit is a metal separated out by electrolytic action. Metallic zirconium, for example, withstands very high temperatures in the open air without oxidising, and its melting and vaporising points where air is excluded are doubtless very high. The author concludes with the statement that there is a broad electrical field still open for the rare earths, and considers them well worthy of further research.

**Electrolytic Dissociation.**—A summary of Mr. Louis Kahlenberg's recent investigations bearing on the theory of electrolytic dissociation appears in the *Journal* of the Chemical Society. The author made experimental observations in connection with the properties of aqueous and non-aqueous solutions, and the results lead him to the conclusion that the theories of solution and electrolytic association are untenable. He remarks that no general agreement between the values of electrolytic dissociation as calculated from the conductivity, and from the vapour pressure, boiling point, or freezing point, has ever been established. Whereas Arrhenius's theory requires that the molecular conductivity shall always increase with dilution, cases are known where it diminishes or remains practically constant. The Nernst-Thomson rule, which ascribes the cause of dissociation to the high specific inductive capacity of the solvent, is not confirmed by later experiments. The additive properties of solutions of electrolytes, which are frequently regarded as evidence in favour of the dissociation theory, really form no argument, for in the case of pure liquids additive relationships are known to exist—for example, in the case of molecular volume and of molecular refractive power. The theory refers the colours of solutions, say, of copper, nickel, and cobalt salts, to the ions, but non-conducting benzene solutions of the oleates of these metals are also blue, green, and red respectively, and the red cobalt solution turns blue on heating, just like the aqueous solutions. Instantaneous reactions cannot be ascribed to ions, for non-conducting benzene solutions of hydrochloric acid and of copper oleate precipitate copper chloride practically instantaneously. The behaviour of acids towards metals in non-aqueous solutions is not in accord with the assumption that the substances owe their characteristic properties to hydrogen ions, for non-conducting solutions of trichloroacetic acid in allylthiocarbimide attack dry magnesium rapidly and decompose the dry alkali carbonates. Thermal data offer difficulties also, and the fact that Ostwald's dilution law holds good for certain organic acids in aqueous solutions is not of general significance. The essential electrolytes do not fit in with the law of mass action in aqueous solution, and in non-aqueous solvents it has yet to be shown that the mass action law is applicable. These and other facts lead the author to conclude that Arrhenius's dissociation theory is useless and misleading. An acceptable theory of solution must not differentiate between the processes of solution and chemical action. A careful consideration of facts shows that these are "identical in character, and chemical compounds are merely the cleavage pieces of solutions placed under special stress or duress represented by the so-called purifying processes." The process of solution thus represents the general case of interaction of substances, union resulting when the specific attraction between them is, under the existing conditions, sufficient to cause a fusion or blending of their masses. In the further investigation of solutions, the most concentrated should receive first consideration, the dilute solutions only appearing as limiting cases. By means of vapour pressure, freezing point, and conductivity measurements carried out systematically on these lines, it should be possible to elaborate a theory of solutions on the basis of chemical affinity acting between solvent and solute.

## BRITISH-MADE TELEPHONES.

### Visit to the General Electric Company's Salford Works.

A considerable amount of correspondence has appeared in our columns this year on the question of British-made telephones, and we have noticed that this correspondence has spread to the daily Press. As is usual in all telephone discussions, the relative merits of imported telephones and those manufactured in this country have not been compared at normal temperature. We are not concerned with the trade interests involved, but wish in this article to give a fair idea of the state of development to which one English firm has brought the manufacture of telephones. The subject is one which borders on the fiscal question, as the Free Trade policy of the country, combined with other considerations, hampers the English manufacturer. We do not refer in this respect to the cheaper grades of telephones used so largely for domestic purposes, or to those instruments employed in offices and factories for interconnection between the different departments. It is in the manufacture of the highest class of instruments and of the exchange apparatus used in public switch-rooms that the English maker has been handicapped. For instance, until

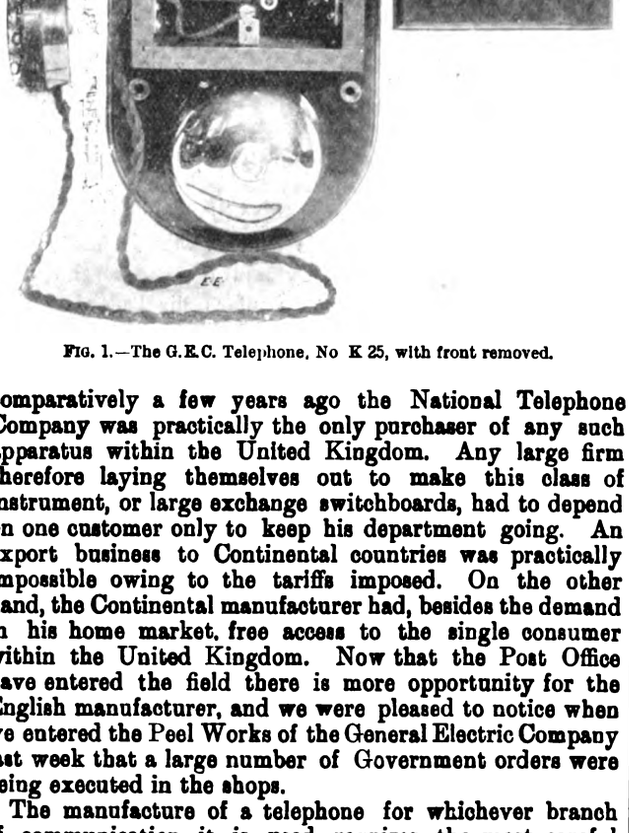

FIG. 1.—The G.E.C. Telephone, No K 25, with front removed.

comparatively a few years ago the National Telephone Company was practically the only purchaser of any such apparatus within the United Kingdom. Any large firm therefore laying themselves out to make this class of instrument, or large exchange switchboards, had to depend on one customer only to keep his department going. An export business to Continental countries was practically impossible owing to the tariffs imposed. On the other hand, the Continental manufacturer had, besides the demand in his home market, free access to the single consumer within the United Kingdom. Now that the Post Office have entered the field there is more opportunity for the English manufacturer, and we were pleased to notice when we entered the Peel Works of the General Electric Company last week that a large number of Government orders were being executed in the shops.

The manufacture of a telephone for whichever branch of communication it is used requires the most careful design, and the detail work involved surpasses that in any other branch in electrical engineering. Coupled with the need of careful design to procure satisfactory working, there is also the question that the instruments have to be produced at rates which will allow of them competing with the manufacturer in other countries where labour is cheaper. This fact gave special interest to the inspection we made of the above works, and we noted with pleasure the numerous labour-saving devices and special tools which have been introduced into the manufacturing process. The number of instruments actually going through the shops was a striking proof that these labour-saving devices and automatic tools have enabled the company to successfully compete on commercial lines in the manufacture of telephones and accessory apparatus. Thus the average output for this the largest department of the Peel Works for the last three years has been as follows: telephone apparatus, 32,500; electric bells, 91,000; electrical indicators, 17,800; switches, 15,000; telegraphic apparatus, 11,250: telephone annunciators and small switchboards, 510; large switchboards, 115. Large as these figures are, the present year promises to show a much greater turnover than the average for the past three years. Thus we saw in course of manufacture for the Post Office a series of instruments forming part of orders for 1,200 central battery type of wall telephones, 5,000 extension magneto bells, and 10,000 Bell receivers. Out of the 1,750 hands now employed at the works, about 1,100 are engaged exclusively in the telephone and telegraph departments. The growth of demand has rendered it necessary to extend the space for

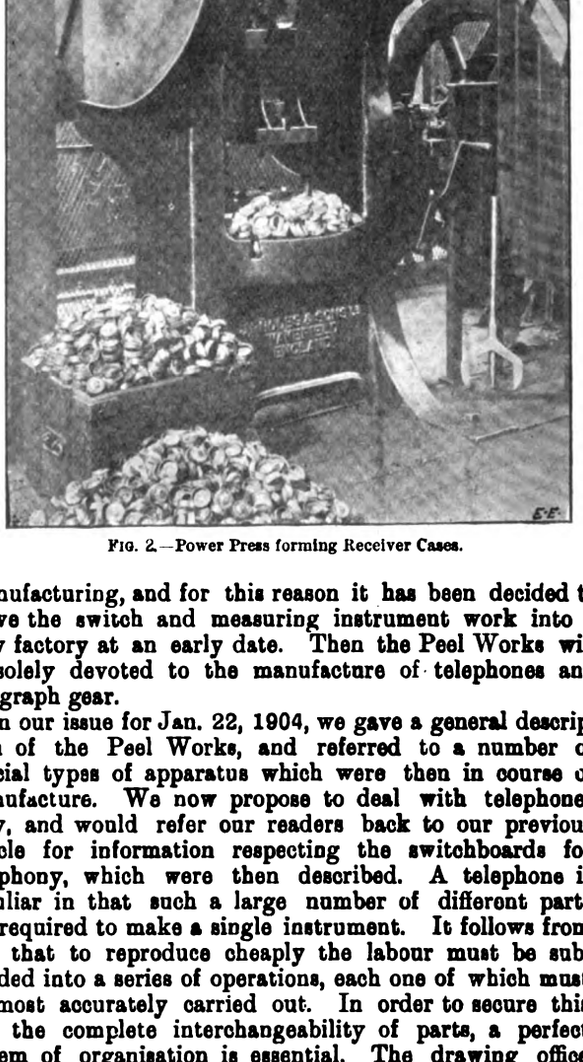

FIG. 2.—Power Press forming Receiver Cases.

manufacturing, and for this reason it has been decided to move the switch and measuring instrument work into a new factory at an early date. Then the Peel Works will be solely devoted to the manufacture of telephones and telegraph gear.

In our issue for Jan. 22, 1904, we gave a general description of the Peel Works, and referred to a number of special types of apparatus which were then in course of manufacture. We now propose to deal with telephones only, and would refer our readers back to our previous article for information respecting the switchboards for telephony, which were then described. A telephone is peculiar in that such a large number of different parts are required to make a single instrument. It follows from this that to reproduce cheaply the labour must be subdivided into a series of operations, each one of which must be most accurately carried out. In order to secure this and the complete interchangeability of parts, a perfect system of organisation is essential. The drawing office department holds the key of the whole position in this respect. We had an opportunity of inspecting a number of working drawings, and were pleased to note that every detail of any instrument is drawn out and dimensioned in a way which affords an easy means of locating any incipient

Digitized by Google

errors. The groups of detailed parts required to build up each element of the complete telephone are kept together, and a special system of numbering adopted. By means of this the parts are easily identified in the store where they

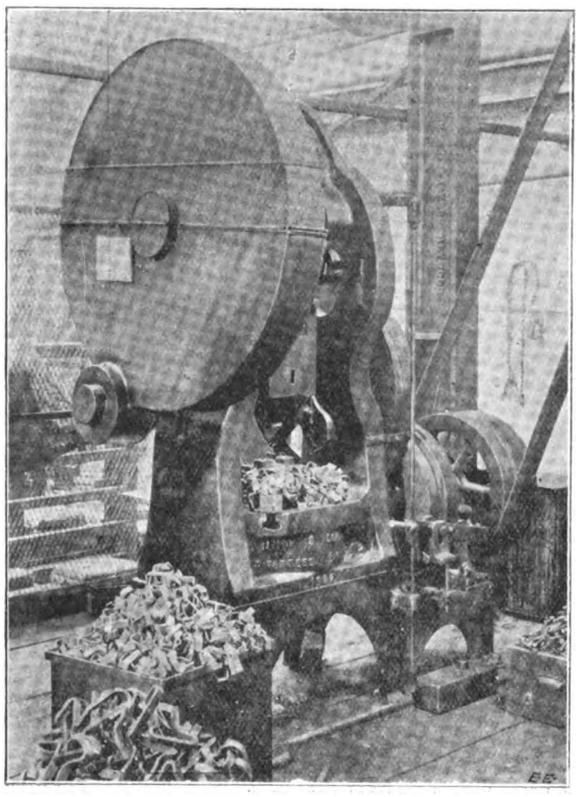

FIG. 3.—Power Press bending Magnets for Telephones.

are collected as manufactured, and from which they are issued to the assembling departments.

We could not attempt in the space at our disposal to describe in detail even a single instrument of one special type, but we propose to draw attention to a few special features in the process of manufacture which struck us as being the outcome of extended experience both of the practical requirements from a telephone and extended experience in the manufacture of the same. The instrument illustrated in Fig. 1 is the K 25 type, which has been produced this year for use in factories and offices. In our illustration we show this instrument with the front cover removed. It will be seen that there are no hinge connections whatever with this instrument, and that the cover is secured by the two screws. These screws also serve to make definite metallic connections with the receiver. The screws are not loose, but held in position by the spring connections to the receiver. The whole of the moving connections inside this telephone are arranged so as to give a good rubbing contact every time the receiver is taken off the hook or replaced. The induction coil used in the instrument is of the Post

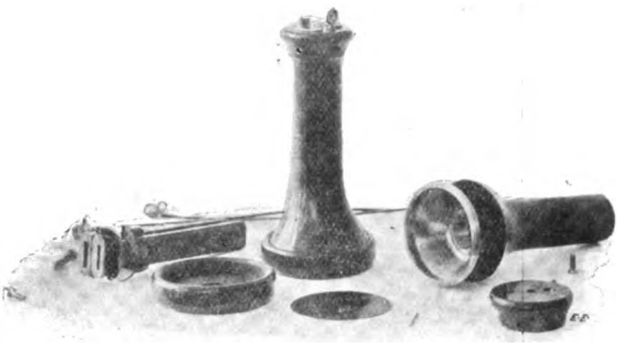

FIG. 5.—Standard Bell Receiver and Parts.

Office pattern, having a resistance of one ohm in the primary and 25 ohms in the secondary. It must be remembered in this connection that the instrument is one which is intended to meet a very large demand by being sold at a low price. The bell has a 25-ohm winding, and the receiver, which is of the watch type, has coils of 30 ohms resistance.

This watch type of receiver is worthy of special mention. We show in Fig. 2 one of the power presses in which the receiver cases are made. These cases are pressed out o sheet brass by means of a series of dies, which dish the flat sheet and mould it into the final shape by a series of interesting operations. The case is given an exterior lip, which is then threaded in a machine so as to receive the ebonite ear-piece. Some 4,000 of these receivers were passing through the power pressing department at the time of our visit. The finished product is a good example of what can be done by the department, as the accuracy obtained is excellent. In the same department we also

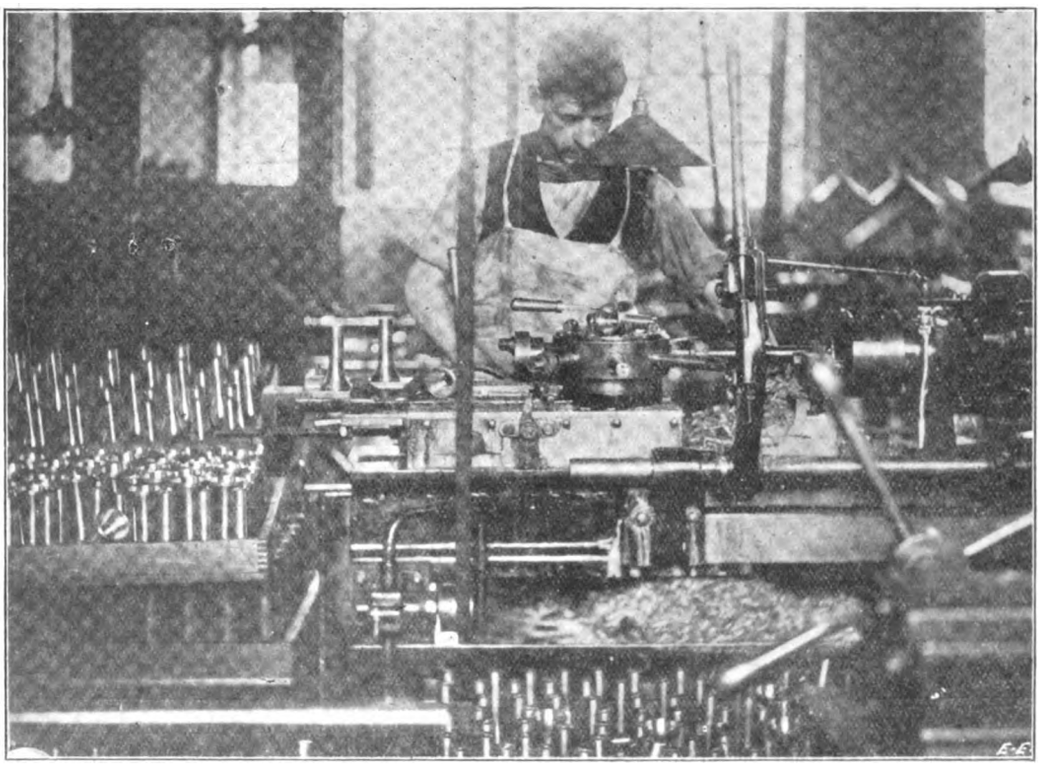

FIG. 4.—Turret Lathe machining the Brass Cases for Standard Bell Receivers.

saw a power press bending the magnets required for the various types of telephones. Fig. 3 is a view of this press, the magnets which are seen on the floor being those required for the table type of magneto instrument. With this type the magnets form the framework of the instrument.

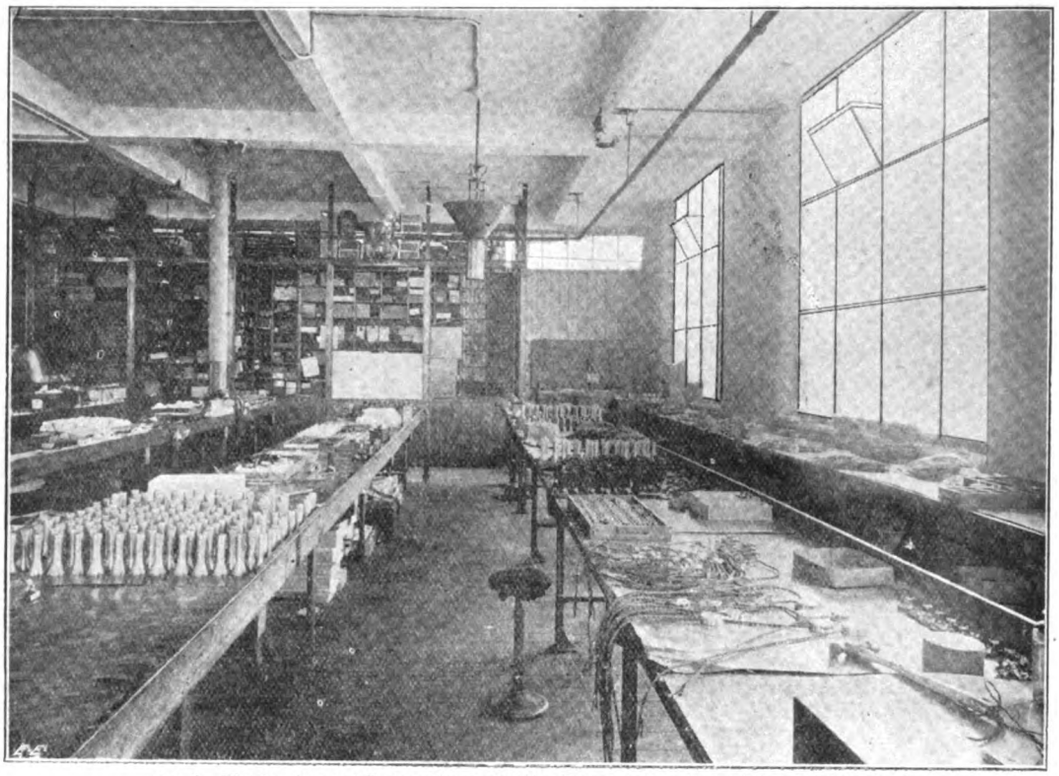

FIG. 6.—The Receiver and Transmitter Assembling Department, with Sub-Stores in background.

Another standard instrument which is being turned out in very large quantities is the Bell type of receiver. In the early days of telephony ebonite cases were used for these receivers, but the ebonite has been found unsuitable in view of the rough usage to which the receivers are sometimes subjected. This is got over by using a brass case as the foundation of the instrument to give the necessary mechanical strength. The machining of these brass cases is now carried out on a special turret lathe with tools which have been designed for the purpose. In Fig. 4 this lathe is shown at work, but to properly appreciate the various operations a full description of each tool would be needed. The brass casting is provided with an extension piece which is gripped in the chuck of the lathe. A number of tools are then brought successively into operation, which bore, turn, and screw the inside of the case. The outside is machined by a special tool with a cutting edge the full length of the case. The outside thread on which the ebonite ear-piece is screwed is then formed, and, lastly, the case is divided from the extension piece by which it has been held. The net result is that the brass casting is finished all over accurately to gauge in an exceedingly short space of time. In Fig. 5 we show an enlarged view of this case, and also of the numerous other

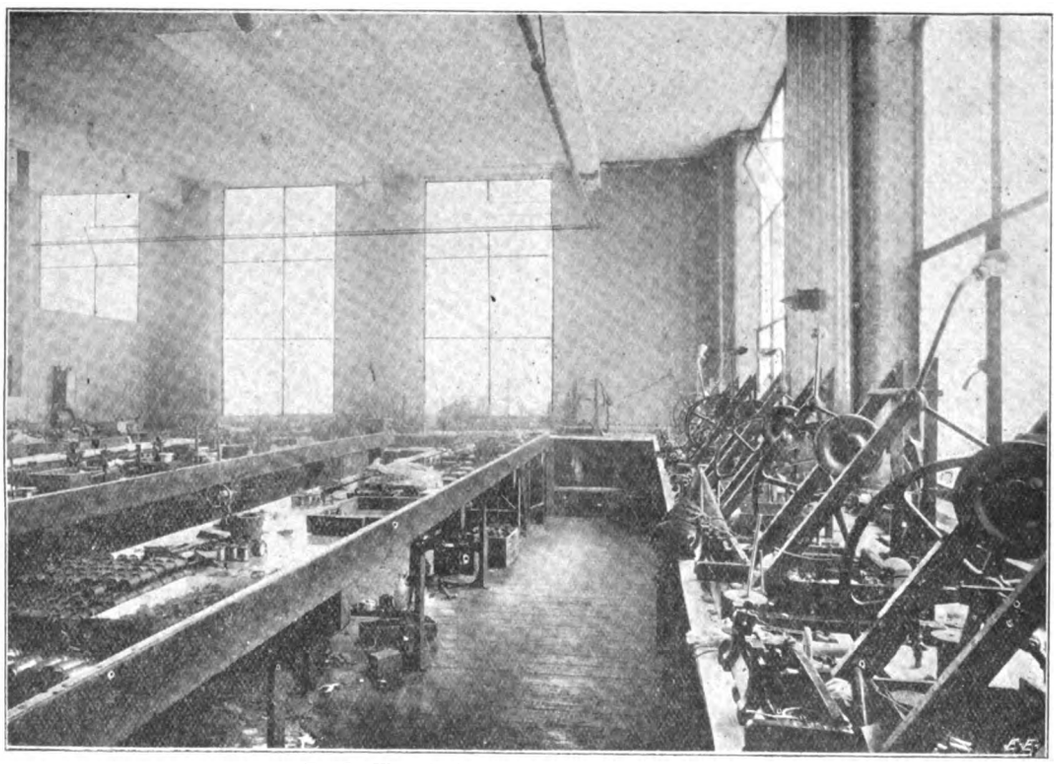

FIG. 7.—View of a Corner in the Coil-Winding Department.

parts which go to make up a complete Bell telephone receiver. The ebonite sheath for the case is also shown. The ebonite from which the ear-piece is made is of special high-grade material, which is exceedingly tough and able to withstand

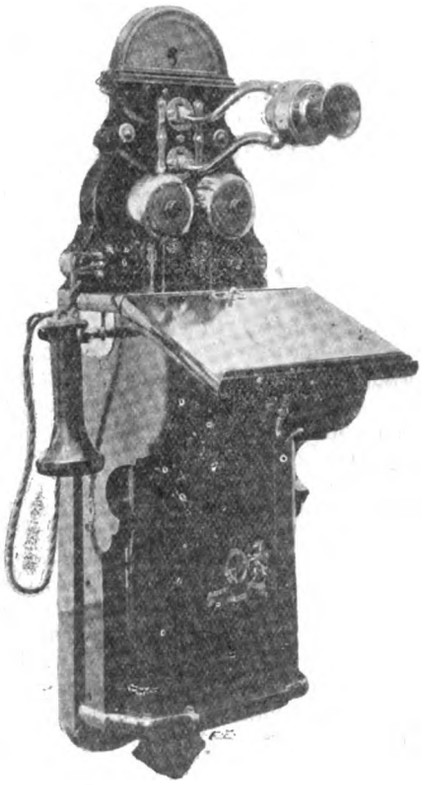

FIG. 8.—Central Battery Type of Wall Telephone made for the Post Office.

rough treatment. As mentioned above, some 10,000 of these receivers were going through the shops at the time of our visit.

In Fig. 6 a view is given of the shop in which the telephone transmitters and receivers are put together. At the back of the department there is to be seen a sub-store from which the materials are issued. In connection with this issuing of parts the firm have an interesting system which facilitates the counting of the materials. A large number of trays are used, each designed to hold in a single layer a definite number of the particular parts in question. The trays thus serve not only as a means of conveniently storing the parts, but also as a check on the number received from the workshop or issued to the assembling department. The workmen in the latter thus receive each day a certain number of trays, the contents of which can be ascertained at a glance. The system affords also a ready check on the operatives, as any damaged material could not be thrown to waste without the fact being noted when the trays are returned to the store after any process has been completed.

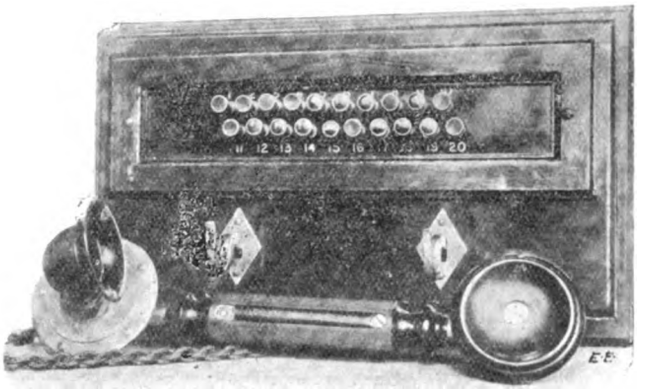

FIG. 9.—The G.E.C. Self-Restoring Intercommunication Telephone.

In Fig. 7 a view of the coil-winding shop is given. The weekly output from this department is in the region of 10,000 coils, all of which are tested both for insulation resistance and circuit resistance before they are passed from the department into the stores. Even these tests are supplemented by others with the same object when the coils have been placed in the completed instrument. An adjoining department which was visited is devoted entirely to the making and braiding of telephone cords.

Perhaps the highest-grade instrument which was going through the shop at the time of our visit was the Post Office central battery signalling wall set, which we illustrate in Fig. 8. The instrument is so designed that a magneto call can be added if desired. An interesting feature in this instrument is the movable transmitter, the vertical height of which can be varied by 6in. As will be seen, the transmitter is carried by two parallel links placed vertically one above the other, and hinged at the one end to the transmitter and at the other to the telephone case. These

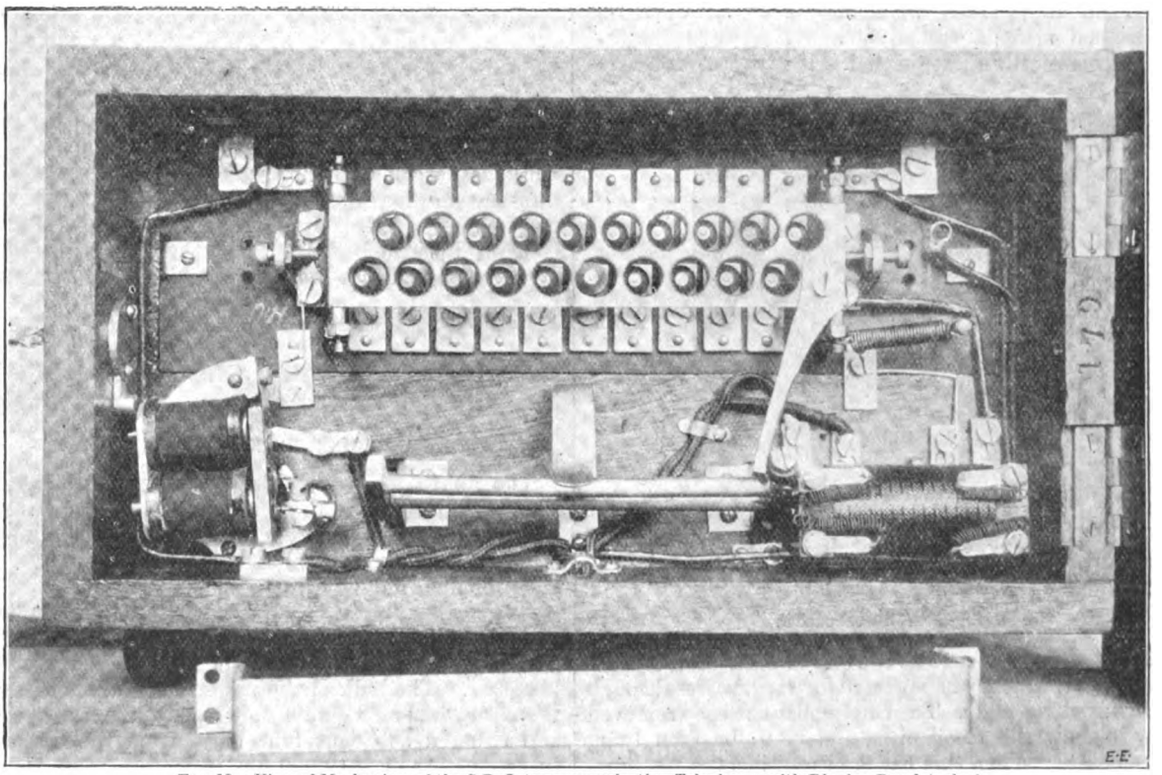

FIG. 10.—View of Mechanism of the S.R. Intercommunication Telephone, with Ringing Bar detached.

Digitized by Google

links, which allow of the transmitter being moved up and down, also serve as the connections respectively to and from the same. The finish of this instrument is remarkable, both the metal-work and the wood case showing excellent workmanship.

The self-replacing intercommunication telephone which we illustrate in Figs. 9 and 10 is not new, but we believe that the ingenious self-replacing device is not well known amongst electrical engineers. In Fig. 10 an illustration of this is given which will enable the details to be followed.

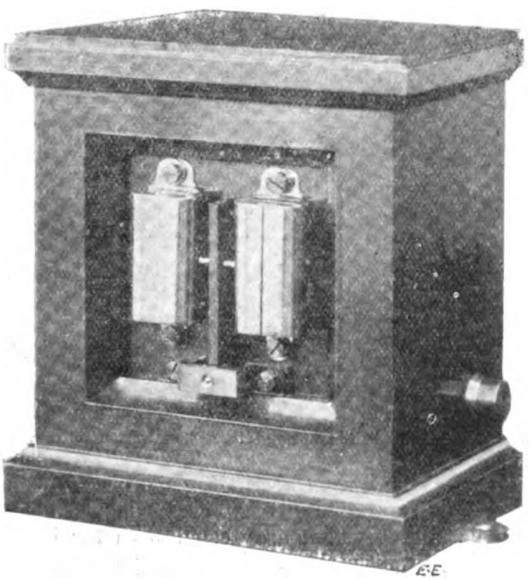

FIG. 11.—Front View of Visual Sounder for Post Office.

The feature of the instrument is the push-button line selector. When one of the buttons seen in Fig. 9 is pressed in, it connects the battery to the line for ringing purposes. When the pressure on the button is removed it does not regain its original position, but, after disconnecting the battery, keeps the instrument connected with the line wanted. When the conversation is completed and the hand combination telephone replaced, the button is released, and all is ready for a new call. If, when one call has been made, a second button is pressed, the first line is automatically disconnected. It will be seen from

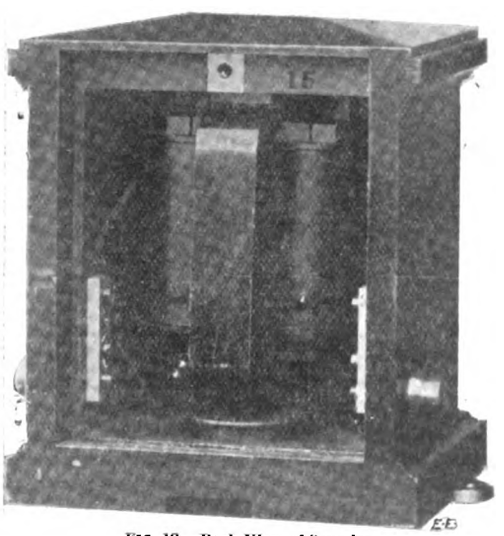

FIG. 12.—Back View of Sounder.

Fig. 10 that there is a cone at the end of each of the push-button spindles, which, when pressed forward, passes through a hole in a rocking plate. The ringing bar has been removed in order to show the mechanism, and is to be seen lying under the case. When this bar is in position, the platinum points at the front of the cone make connnection with it for ringing. On the return stroke of the push button the under side of the cone engages of the face of the rocking plate, and connection is made for speaking. The holes in this plate are countersunk from the back, so that if a second push button is pressed it moves the plate sufficiently to let the edge of the first cone slide down the countersunk surface and break contact. The long finger secured from one end of the rocking plate moves the same, and disconnects the line when the telephone is again hung on the hooks. With this arrangement, unless there is carelessness in pressing two buttons simultaneously, it is impossible to get more than one connection made at the same time. While this does not necessarily mean secrecy, it goes farther in that direction than the ordinary type of sliding contact switch, and it gives at the same time an automatic clearing at the end of each message.

Before leaving the references to special instruments, we would refer briefly to the new telegraph sounder (Fig. 11), which we saw both completed and in course of manufacture for the General Post Office. The advantage of the new type is that it can be read either by sight or sound, and it can be worked on most lines without the interposition of a relay. The resistance of the coils of this instrument is as high as 4,500 ohms. In the same department we notice a new indicator for the same department for showing the exact instant at which an engaged trunk line is set free. The indicator depended for its signalling on an electro-magnetic holding up a disc. Here, again, the details in workmanship were a credit to the department in which the instrument was being made.

We have not referred in detail to a large number of the departments visited, nor even to the woodworking shops, in which the seasoned woods of various kinds are handled. It suffices, perhaps, to say that in this, as elsewhere in the factory, machines for the reproduction of parts in quantities are extensively employed. All the holes are drilled in the wood cases and other parts of the telephone before the wood is polished and delivered to the assembling departments. This being done accurately with jigs and templates, there is little margin for personal error when the instruments are being put together. Before any instrument however small is allowed to leave the works it is subjected to two tests, first by the foreman under whose supervision it was put together, and then in the independent testing department. A casual inspection of this latter department would leave some doubt as to the mental condition of the staff.

It remains to be said that the General Electric Company first commenced to make telephones in 1888, and the department has grown year by year since then. The manufacturing is carried out under the supervision of Mr. A. Brooker, as works manager, and his assistant-managers, Mr. A. Trafford and Mr. G. C. Vyle. Mr. P. P. Kipping has taken up the commercial management of the telephone, telegraph, and signalling departments of the company. He and Mr. Brooker kindly showed us the works last week, and our thanks are due to them for the information given above. Last, but by no means least, we must mention Mr. Max Byng, who, as director of the General Electric Company, had the courage to start the department, and has been responsible for its success.

## THE BLAST-FURNACE GAS-POWER PLANT AT THE ILSEDER IRON AND STEEL WORKS.

BY G. HOOGHWINKEL, MIEE, MIME.

The above plant may be considered, perhaps, the first successful installation of its kind on a large and commercial basis. As may be seen from the illustrations, the plant has been designed on a liberal scale, and it has been the writer's good fortune to have been connected with it.

At the time the furnace plant consisted of four furnaces, producing 220 tons of pig iron per diem each, which give off enough gas to supply about 15,000 e.h.p. for outside purposes. The bulk of the power had to be transmitted to the steelworks at Peine belonging to the same company, and situated at about four miles from the Ilseder blast furnaces. As over 12,000 h.p. in motors were required at Peine, a liberal amount of surplus gas had to be provided, and, therefore, the steam-driven blowers were replaced by gas-driven ones. Formerly the steam was supplied by gas fired boilers, but the amount of gas required was found to be about four times as much as when used direct in the gas-engines. The gas-driven blower shown in the illustration is actually installed at the Nieder-Rhine Steelworks,

Digitized by Google

and is identical with the two installed at the Ilseder furnaces. These two blowers required about 500 h.p. each. The engine-house, as shown in the illustrations, contains six sets of 1,000 h.p. to 1,200 h.p. each, but there is room for four more.

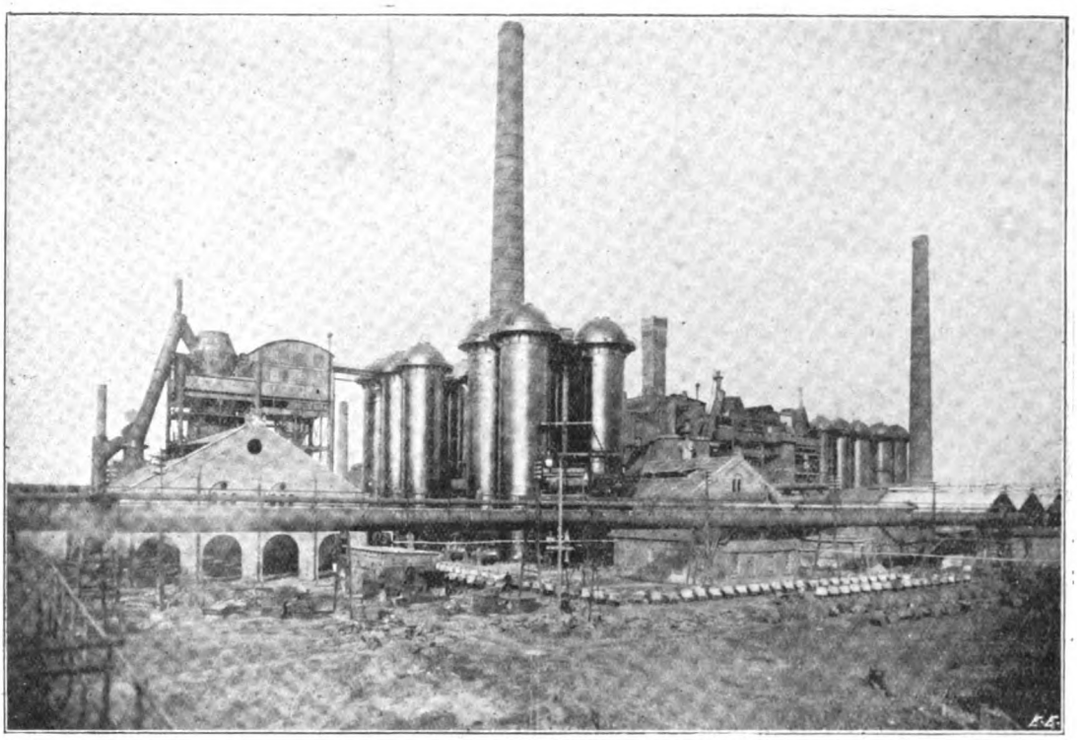

FIG. 1.—The Blast Furnaces at Ilseder (Westphalia).

Before reaching the gas-engines the gas is cleansed and cooled. The Ilseder blast-furnace gas plant being one of the first installations of its kind, the cleaning of the gases has not been carried so far as is now generally being recog-

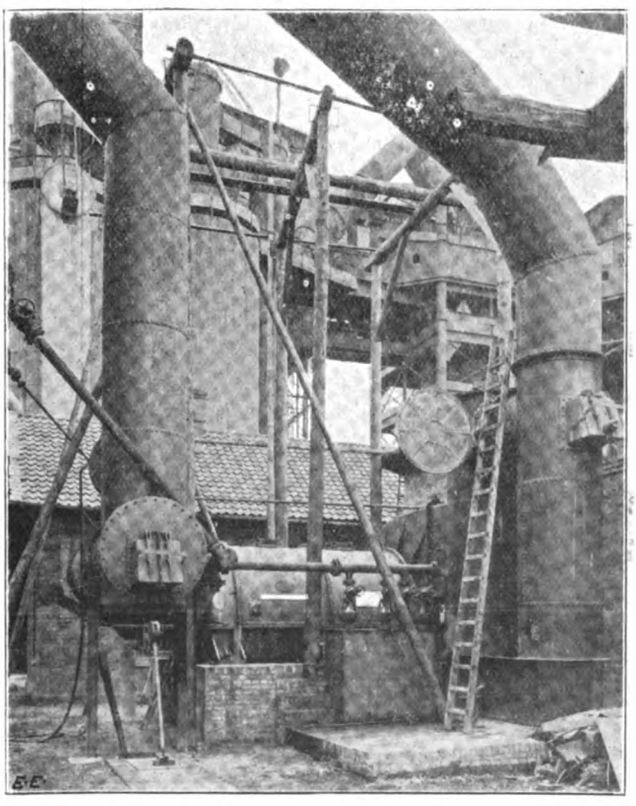

FIG. 2.—The Theisen Gas-Washing Plant at the Ilseder Blast Furnaces.

nised as desirable. That, however, with these imperfectly cleaned gases such good results have been obtained is a proof of the thorough construction of the gas-engines used. The cleaning relies mostly on two rotary washing plants of the Theissen type and a long gas-main. These Theissen exhaust washers consist mainly of a triple-concentric drum revolving at some 300 revolutions, in which the hot gases are thrown against the outside cover, which is continually cooled by trickling water. In this way the gases and the water are efficiently mixed, while at the same time the fan draws the gases from the furnace caps. These washers deal with 25,000 cubic feet of gas per minute, and require only 110 h.p., while the water consumption is about 50 gallons per minute. The relatively small dimensions of the cleaning plant can easily be seen from the photograph. The power station consists of two bays 147ft. by 214ft. long and 56ft. high, spanned by a 25-ton travelling crane.

The gas-engines are of the Oechelhauser type on the two-cycle principle, two separate engines each with one power cylinder driving one dynamo, one on each side. These engines are exceedingly simple in design, although from the photographs this does not show off sufficiently owing to the many rods and separate pump. There are no valves, thus removing the principal cause of trouble of a gas-engine working with blast-furnace gas. The cylinder is open on both sides, another simplifying feature. Of course, the separate pump has the disadvantage of a slightly lower efficiency for the whole engine, as the power to drive it requires about 10 per cent. of the output. However, the total efficiency is only about 3 to 4 per cent. lower than other four-cycle engines, but the increased simplicity is so all-important in blast-furnace works that this disadvantage is not to be regarded at all. These engines are so well balanced in the parts that the coefficient of angular velocity variation is as low as 1/350 with a flywheel of only 25 tons combined with the dynamo rotor. The speed is 125 revolutions. Each engine has its own exhaust carried outside the station, as may be seen from the photograph.

The dynamos are of the flywheel type and of the well-known Siemens design, while the switchboard is a model of roomy and simple construction, as is shown in the photograph of the high-tension switchroom. Some of the power is used at the furnaces for chargers and lifts, cranes and trams, but the bulk of the power is required for their own steelworks and rolling mills, situated at a distance of about four miles from the blast furnaces. This power supply may be divided into three separate classes:

1. The Bessemer steelworks—requiring power for blowers for the converters, mixers, blowers and ventilators, fans for the furnaces, pumps for the hydraulic compressors, casting machines, and other auxiliary machines.

2. The rolling mills—requiring power for the mills, the

Digitized by Google

rolling trains or rollers, the hot saw, the shears, the presses, the pumps for the hydraulic compressors.

3. Tools and machines for various purposes—cranes, locomotives, boiler feed pumps, lifts, transmissions, etc.

use continuous-current motors for the mills, rollers, cranes, and Bessemer converters, and alternating-current motors for all the other machinery. The total supply for power purposes was about 12,500 h.p.

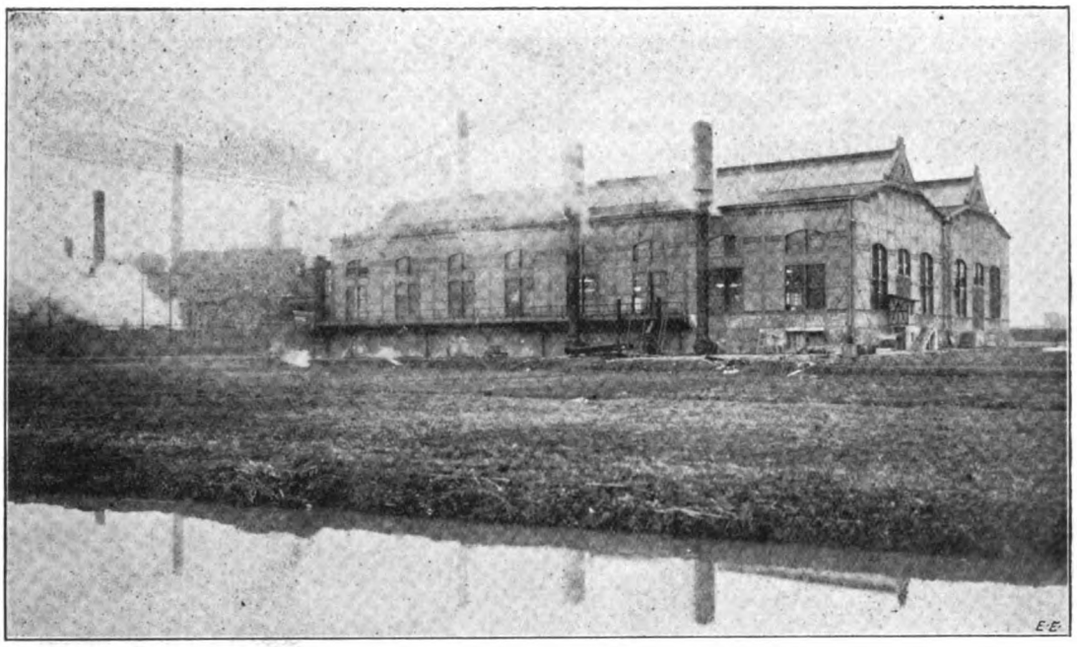

FIG. 3.—Exterior View of Ilseder Power Station, with Gas-Driven Plant.

It was, of course, thought desirable to apply the electric power on the same system as it is transmitted from the power station, at 10,000 volts 50 periods alternating current. Alternating-current motors are preferable on many points, and for nearly all the machines in the steelworks, except those where variable speed and heavy starting efforts are required. We are now, however, going in the right direction to adapt the alternating-current motor even to those requirements, but at the time the installation under review was designed it was decided to

The reason for adopting continuous current for the rolling mills was that, in order to overcome the huge starting efforts when the ingots are introduced in the mill, a heavy flywheel was mounted on the motor shaft. The duty of these flywheels was to give off energy at times of overload, and this can, of course, only be attained by a lowering of the motor speed. If the flywheel is not to have a too heavy weight (owing to the slow speed), speed reductions of 10 to 20 per cent. are required, and this is impossible with alternating-current motors, unless auto-

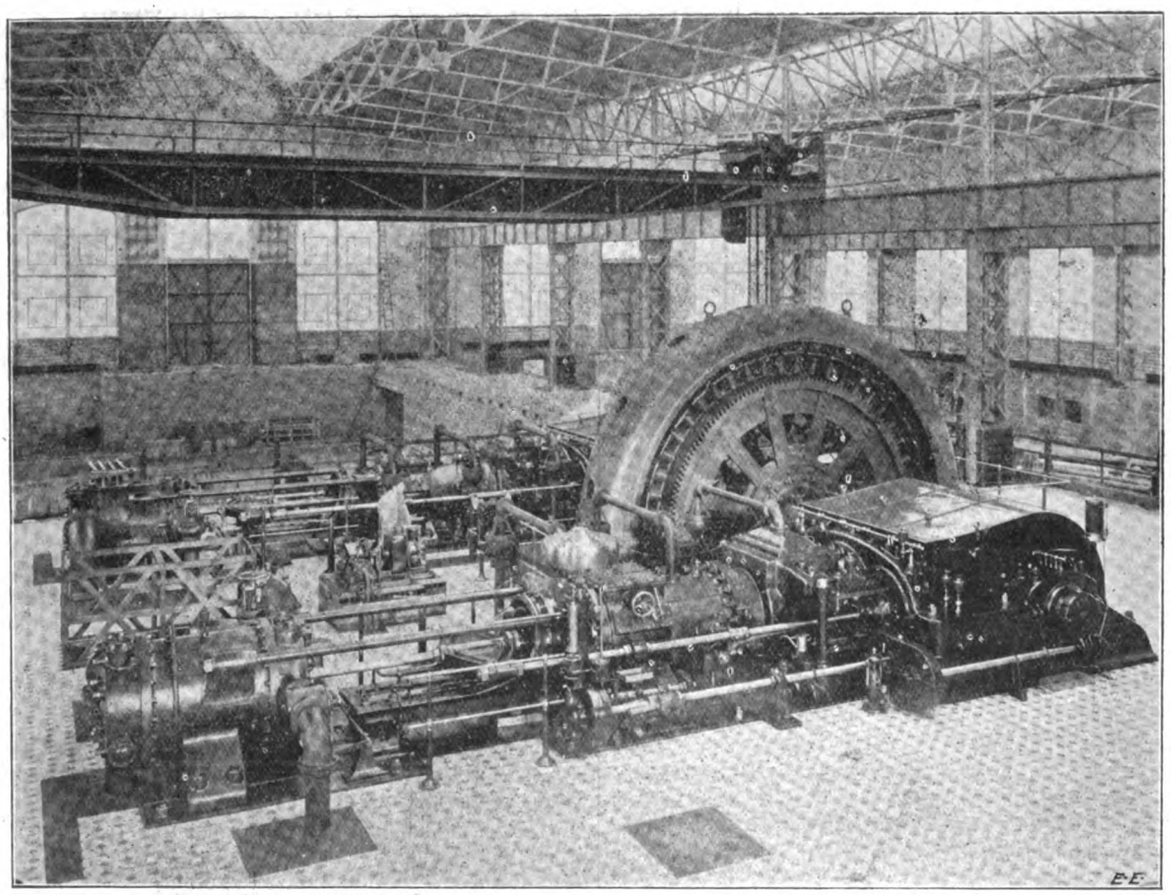

FIG. 4.—Inside of Power Station, showing Oechelhauser 1,000-h.p. 125 revs. Gas-Engine coupled to 10,000-volt Dynamo.

Digitized by Google

matic resistances are inserted in the rotor circuit in order to increase the slip. This cannot be calculated beforehand, but must be adjusted on site, which is inconvenient and costly; besides, the resistances have the effect of lowering the efficiency considerably. The smaller and high-speed machines, however, are all driven by alternating-current motors, as the flywheels may be made heavier in proportion to the speed; and these small motors permit a greater slip.

batteries of the sub-stations. An additional advantage of the compound continuous-current motor for rolling mills was that these motors may be regulated for several fundamental speeds, required by the rolling of various materials and sizes, by regulating the shunt for each speed. Alternating-current motors would have required huge resistances in the rotor circuit, which would reduce the torque almost in the same proportion to the speed (20 to 30 per cent.).

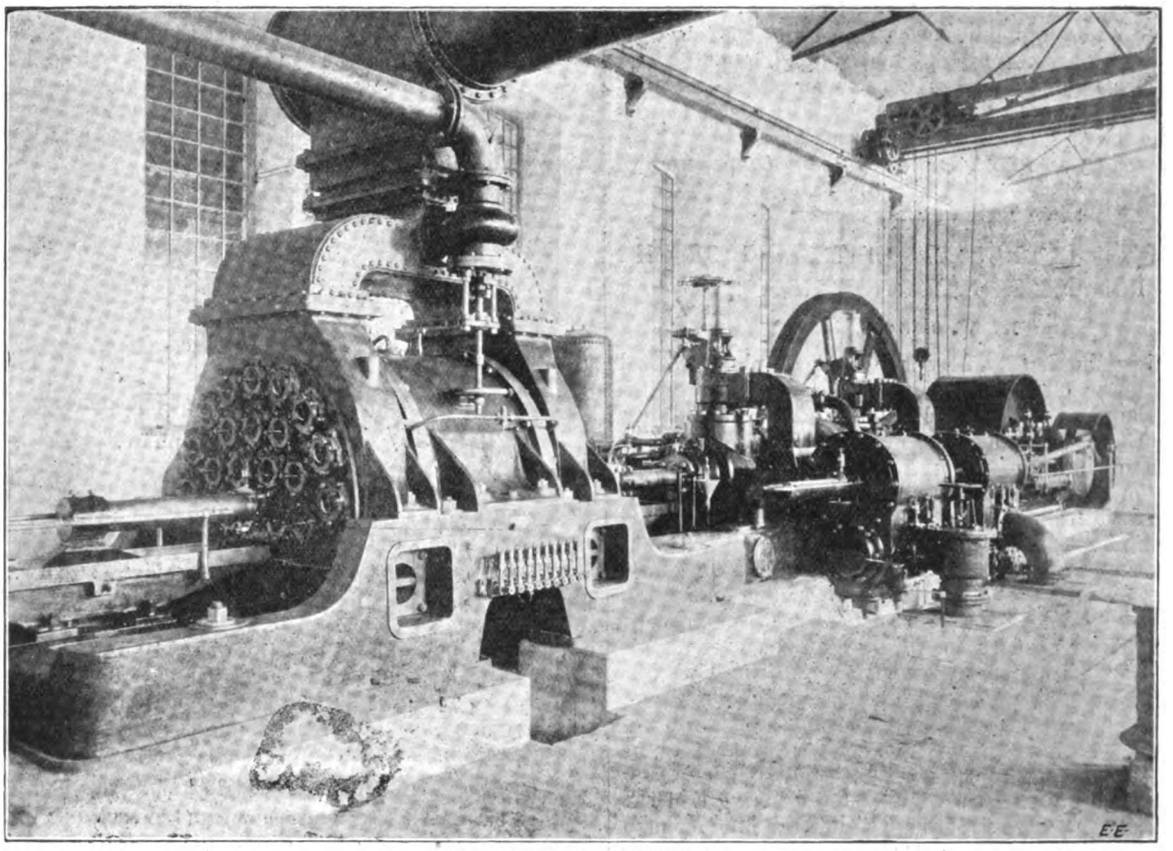

FIG. 5.—Gas-Driven Blowing Engine.

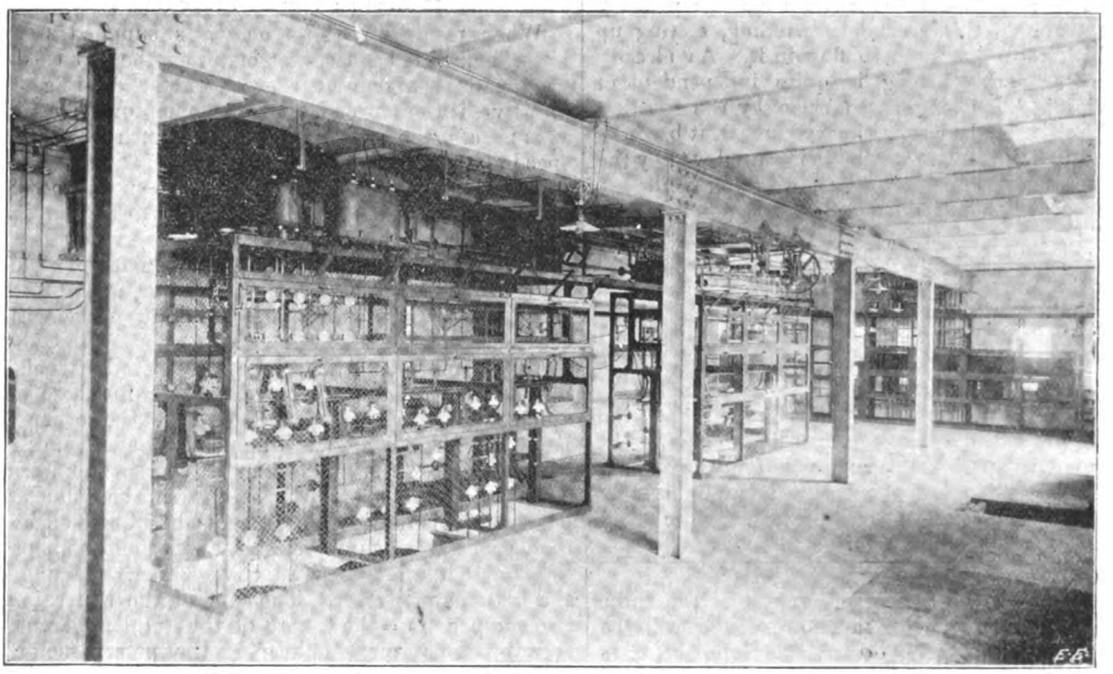

FIG. 6.—The Back of the 10,000-volt Switchboard.

Another disadvantage of the alternating-current motors for the rolling mills are the huge irregularities at the power station which would react on the gas-engines. Some motors require 2,000 h.p. at full load, so the effect may be imagined, and the power station would have had to be much larger. Now the much smaller variations are taken up in the

The high-tension alternating current supplies two sub-stations situated near the centres of supply (*vid* the cogging mills), one containing three 800-kw. rotaries and two 500-kw. transformers (10,000 volts to 500 volts), and a battery of 1,660 ampere-hours capacity; while the other sub-station contains five 800-kw. rotaries, two 800-kw.

Digitized by Google

transformers, and a battery of 2,200 ampere-hours capacity. The main conductors to the various shops are laid as cables to avoid short-circuits and a clumsy superstructure, and as a 500-volt supply for power is taken as a standard all conductors are kept out of reach.

The lighting of the shops is taken from the main high-tension three-phase supply, twice transformed down, once in the sub-stations and once in each shop. The offices and dwellings are lighted by continuous current from the sub-stations. The savings introduced by the extensive utilisation of the waste gases from the furnaces at Ilseve, have effected a reduction in production costs of 6s. per ton of pig made.

## NOTES ON THE THEORY AND TESTING OF THE POLYPHASE INDUCTION MOTOR.

BY W. ROGERS.

As an introduction it will not be out of place to deal briefly with the elementary side of this subject, notwithstanding the fact that it is well understood by all readers of this journal. The polyphase induction motor consists of two separate windings—viz., the primary or stator, and the secondary or rotor. The primary winding receives a polyphase current from a source of supply: it is, therefore, strictly speaking, an armature. The secondary winding has no connection with the supply circuit, being magnetised by induction from the primary. Although either the primary or secondary circuits may form the revolving part, it is usual to keep the primary circuit stationary, as it avoids exposing the high-voltage winding to the strains which accompany rotation. When the primary winding, which is made up of coils connected up in groups overlapping each other, is energised by a polyphase current, a rotating magnetic field is set up, which gives rise to a series of alternating E.M.F.'s in the windings. The current supplied to the primary may be divided into two parts: (1) that part representing energy usefully expended or absorbed in heating; (2) the part employed in magnetising, and which is known as the magnetising current. The secondary may be either wound with coils or built up by inserting copper bars in the slots forming the rotor core and connecting the extremities of the parallel conductors together, forming a short-circuited secondary. The magnetic fields set up by the primary current pass through this secondary winding, setting up E.M.F.'s, which cause currents to flow in it. As already stated, this secondary winding is quite independent of the supply circuit, but being acted upon by the rotating magnetic field, generated by the primary current, it becomes the seat of induced currents, rotation being produced by the reaction between these currents and the rotating field.

The no-load speed of an induction motor is equal to the number of alternations of the supply current ÷ number of poles. Should the rotor by any means be made to run at its actual synchronous speed, it would cease to be acted on inductively, and would exert no turning effort. This difference between the no-load speed and the synchronous speed is known as the slip, and is expressed as a percentage of the maximum speed. As the load on a motor is increased the slip also increases, in order that the motor may run with a greater turning effort. In fact, a drop in speed is necessary for developing any torque, and this may be proved quite clearly as follows: The speed of the rotating magnetic field of an induction motor $= \frac{\text{number of alternations of supply}}{\text{number of poles}}$ and may be assumed to be almost constant. If the rotor and the rotating field run at the same speed, they will be stationary with regard to each other; therefore, the lines of force due to the rotating field cannot cut the conductors of the rotor, and so give rise to induced currents in it, which are necessary for a torque It will thus be seen that any increase in the difference in speed of the rotating field and the rotor, caused by load being thrown on, gives rise to an increased torque, and the greater the difference in speed between the field and rotor the greater will be the rate of cutting the field by the rotor, which will result in an increase in the E.M.F.'s set up in it, and thus an increase in the secondary current and torque. For any load thrown on a motor (within the limits of its load) the rotor speed will continue to fall, and the E.M.F.'s induced in the rotor will continue to increase, until the torque delivered is sufficient for the motor to carry that particular load.

The current taken by an induction motor of given output and voltage depends upon the number of phases, power factor, and efficiency, the currents taken by a single, two-phase, or three-phase motor being found by using the following formulæ. The amperes per terminal at line voltage, V, required to develop horse-power, H, in a motor having an apparent efficiency, $\eta$,

$$= \frac{746 \times H}{\eta \times V} \text{ for single-phase.}$$

$$= \frac{746 \times H}{\eta \times V} \times \tfrac{1}{2} \text{ for two-phase.}$$

$$= \frac{746 \times H}{\eta \times V} \times \frac{1}{\sqrt{3}} \text{ for three-phase.}$$

The line current per phase in a three-phase motor

$$= \sqrt{3} \times \text{current in one phase.}$$

Current per phase in any motor

$$= \frac{\text{H.P.} \times 746}{\text{Efficiency} \times \cos\phi \times \text{line volts} \times \text{number of phases}}.$$

The watts input are the same for a single, two, or three phase motor of given output, but the input current depends upon the number of phases.

For example, take the case of a 10-h.p motor, 200 volts, efficiency = ·85 and power factor = ·8. Then true watts = 10 × 746 ÷ ·85 = 8,776, and apparent watts = 8,775 ÷ ·8 = 10,970.

With a single-phase winding line, current

$$= 10{,}970 \div 200 = 54{\cdot}85 \text{ amperes.}$$

With two-phase (four wires), current in each line

$$= 10{,}970 \div (200 \times 2) = 27{\cdot}4 \text{ amperes.}$$

With a three-phase winding, with 200 volts between lines, line current

$$= 10{,}970 \div (200 \times \sqrt{3}) = 31{\cdot}7 \text{ amperes.}$$

As the line current = $\sqrt{3}$ × phase current, then the phase current

$$= 10{,}970 \div (3 \times 200) = 18{\cdot}3 \text{ amperes.}$$

When measuring the true watts supplied to a three-phase motor, if the two-wattmeter method is used it will be found that one of the wattmeter readings will be negative, if the power factor of the motor be less than ·5, as is usually the case when it is run much below its rated speed at reduced voltage.

The true power supplied to a motor = useful power given out on motor shaft + iron, copper, and friction losses. Also apparent power supplied = primary amperes × volts. Power factor = true power ÷ apparent power. The apparent power is always greater than the true power, owing to the fact that the primary currents are not in phase with their E.M.F.'s.

The primary current may be considered as being made up of two currents, one current being in phase with the applied voltage, giving true energy, the other current lagging 90deg. behind the applied voltage, being wattless and giving no energy. The first current is known as the energy component, and the second as the inductive component. This inductive component has a bad effect on the regulation of the supply circuit, and should be kept as low as possible if a motor is to have a large starting torque and high power factor. The sum of the squares of these two components = the square of the total apparent input, and the importance of keeping the power factor of an induction motor as high as possible may be shown in a very simple way. Suppose a motor has a power factor of 90 per cent., then the inductive component of the current

$$= \sqrt{\text{total current}^2 - \text{energy component}^2}$$

$$= \sqrt{100^2 - 90^2} = 43{\cdot}6.$$

That is to say, that with a power factor of 90 per cent., the portion of the current that is lagging 90deg. behind the E.M.F. is equal to 43·6 per cent. of the total current.

Digitized by Google

The inductive component in an induction motor depends upon the magnetising current and also upon the magnetic leakage, and in practice it is usual to express the inductive component and the magnetising current as a percentage of the total primary current, magnetic leakage being expressed as a percentage of the magnetic flux due to the primary current. If the magnetising current is 30 per cent. and magnetic leakage is 12 per cent., this will give an inductive component of 42 per cent. of the total primary current, which corresponds nearly to a power factor of 90 per cent.

When an induction motor is running on full load, a low leakage and a high magnetising current will give the same power factor as a high leakage and low magnetising current, but when the motor runs at half load the percentage magnetising current is nearly doubled, while the magnetic leakage is halved. It will, therefore, be seen that it is necessary to have a small magnetising current when a high power factor is required. From what has already been stated above, it follows that the power factor is the ratio of the energy component to the total apparent input, and if the power factor and apparent input are known, the values of the inductive and energy components can be easily obtained. A large inductive component means a low power factor, which may be raised by increasing the energy component, but if the inductive component is kept at its same value, the efficiency is not much improved. When starting an induction motor the energy component may be taken as a measure of the torque, but a large consumption of power at starting does not necessarily mean a large starting torque. We shall now consider some methods of starting up and regulating the speed of an induction motor. Although it is possible to start a polyphase motor by simply connecting it to the supply mains, it is not advisable to do so except in the case of motors of small size. If large motors were started in this manner, it would result in large currents being drawn from the supply, which would interfere with other parts of the system, and also do injury to the motors themselves.

The following gives a brief review of the methods at present in use :

*Method I.*—The motor is connected directly to the supply mains, which method is, as already stated, only suitable for small machines. When a motor is just starting, the rotating magetic field rotates at a very high speed relatively to the rotor, consequently the E.M.F. induced in the rotor will be high, which will result in large induced currents being set up in it for reasons already given in the commencement of this article. At starting, the induction motor may be considered as a transformer having a large air-gap in its magnetic circuit, as it takes a large wattless current from the supply to produce a magnetic field in the air-gap. The large current taken at starting of an induction motor is, therefore, similar to the high magnetising current taken by a transformer having insufficient iron in its core, and, as will be readily understood, the effects mentioned above will be greatly increased in large motors. The evil effects of the large currents taken by motors at starting may be considered as follows : The large wattless current taken from the supply causes a large voltage drop in the generator, owing to its demagnetising action on the generator field. It also tends to demagnetise the motor field, decreasing the magnetic flux and increasing the leakage between the primary and secondary windings.

*Method II.*—This method employs a variable resistance in the secondary circuit. The insertion of a non-inductive resistance in the rotor circuit at starting is a very simple and effective method of preventing excessive currents and the demagnetising effect on the motor field, at the same time increasing the torque, the torque being directly proportional to the rotor resistance at starting and inversely proportional when running at normal loads. When a wide variation in speed is desired, this method requires a large number of contacts on the rheostat, which then becomes complicated and cumbersome.

There is another method, due to Mr. Fisher-Hinnen, in which the resistance is cut out automatically as the speed rises, and the following explanation will show how this is brought about. Now, at starting the frequency of the rotor and stator currents is the same, but as the speed rises the frequency of the rotor currents falls off, being only a small fraction of the frequency of the stator currents, when the rotor is running at full speed. In each of the rotor circuits a high non-inductive resistance is inserted, which is shunted by a reactance coil, C, having a small ohmic resistance, but a high coefficient of self-induction, L. The reactance, R, of this coil depends upon the frequency of the E.M.F. Now, the frequency is proportional to the slip, and the slip varies with the speed, the slip being at its maximum at starting, falling to nearly zero at normal speed. It will, therefore, be seen that any variation in speed varies the reactance, which also falls from a maximum to nearly zero. The impedance of the rotor circuit = resistance + reactance in series. Joint resistance $= \frac{C R^2}{C^2 + R^2}$ and joint reactance $= \frac{C^2 R}{C^2 + R^2}$.

At starting the reactance, R, is at its maximum, therefore the joint resistance is also a maximum. As the speed rises and the frequency in the rotor circuit decreases, the apparent resistance of the reactance coil diminishes, the ohmic resistance being then shunted by an apparent resistance, which is constantly falling in value until the motor reaches its full speed, when the joint resistance is nearly zero, because the reactance is nearly zero. This device enables an induction motor to start up under load with a small current, automatically increasing its speed till the normal speed is reached. Fig. 1 shows connections for

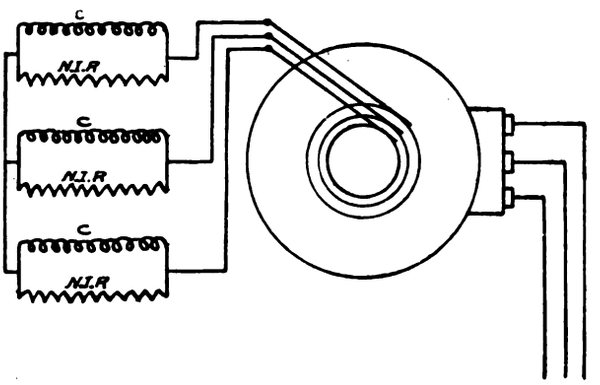

FIG. 1.

this method. C and R are resistances and reactances in parallel. This starter is always in circuit, and the only bad effect this has on the running of the motor is to cause a slight increase in the slip and a small decrease in the power factor.

Another method employs an auto-transformer to vary the voltage supplied to the motor. An auto-transformer consists of a coil of wire wound on an iron core and connected across the supply mains. The coil has a large number of turns and several tappings, so that different voltages may be supplied to the motor. The auto-transformer permits large currents at low voltage to be supplied to the motor, while a small current at high voltage is taken from the mains, and when the motor has reached its full speed it may be cut out of circuit. This method requires no slip-rings on the motor, and a short-circuited rotor may be employed. Satisfactory working of an auto-transformer is only obtained when it is employed to start up the motor for which it was designed. Fig. 2 shows the connections of an auto-starter for two-phase motors.

Another method of varying the speed is to wind the stator in such a way that it is possible to alter the number of poles. By halving the number of poles the synchronous speed is doubled, the slip remaining the same as before for any given load. A great disadvantage of this method is the large number of cable connections which it involves, and for this reason it is not often met with in present-day practice.

Having briefly described the different methods of varying the speed, it will be interesting to further consider the speed, and its relation to the torque exerted, also the conditions on which both depend. We have already seen that when load is thrown on a motor, its speed will continue to fall, and the E.M.F.'s induced in the rotor circuits will

Digitized by Google

continue to increase until the torque developed is sufficient to run the motor at that particular load. By further increasing the load, the speed will continue to fall and the torque increase, until finally zero speed is reached, and if the different speeds and their corresponding values of torque are plotted, the resultant curve should be a straight line, as $E^1$ (Fig. 3). It will be found, however, that an actual speed-torque curve takes the form of $E^2$, owing to

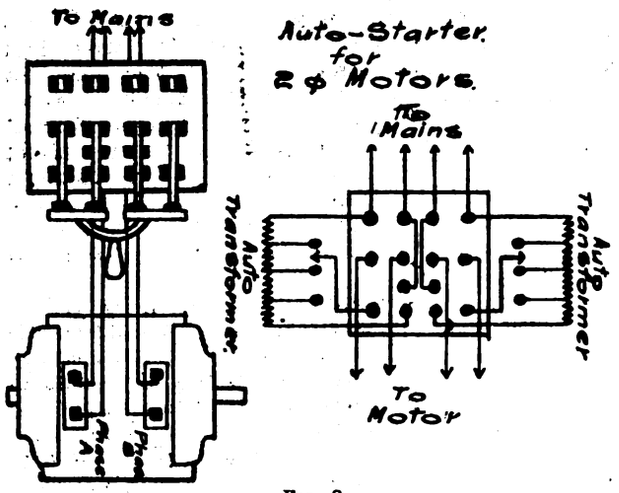

FIG. 2.

the following reasons: A certain part of the voltage impressed on the primary winding supplies the C R loss in it due to its resistance, and if the impressed voltage is kept constant the counter E.M.F. of the primary will diminish as the C R drop increases, and the magnetic field required will also be diminished. Therefore to generate the required induced currents in the rotor the speed must drop more than is shown in curve $E^1$—that is to say, the speed-torque curve is curved, and not a straight line.

leakage and a low secondary resistance the speed-torque curve assumes the shape of $E^3$ (Fig. 3). It will be seen that the torque increases as the speed falls, until its value reaches a certain maximum, and if the speed continues to fall through a further increase in load after this point is reached, the torque will gradually fall until the motor stops. A motor must, therefore, have its rated load below this point, which is known as the pulling-out point. The

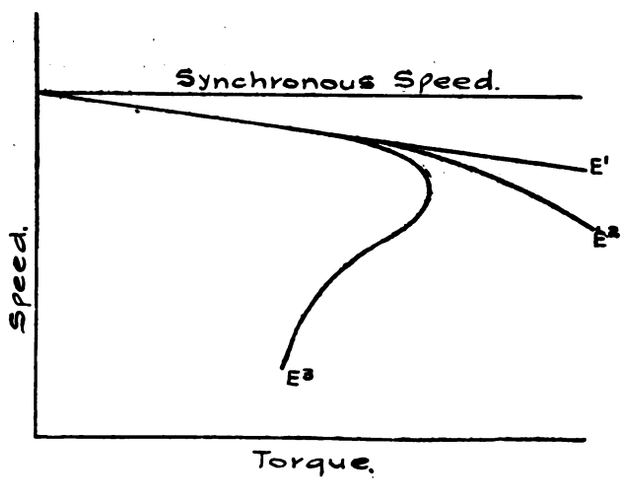

FIG. 3.

speed-torque curve is of the greatest importance, as on it depends the starting torque and speed regulation of the motor. At this point it will be necessary to take into account the effect of the secondary resistance on the speed curve; any increase in the secondary resistance requires a proportionate increase in the slip if the torque is to be kept constant, because an increased resistance in the rotor circuit requires a higher E.M.F. to drive through it the induced currents necessary for that particular torque. If

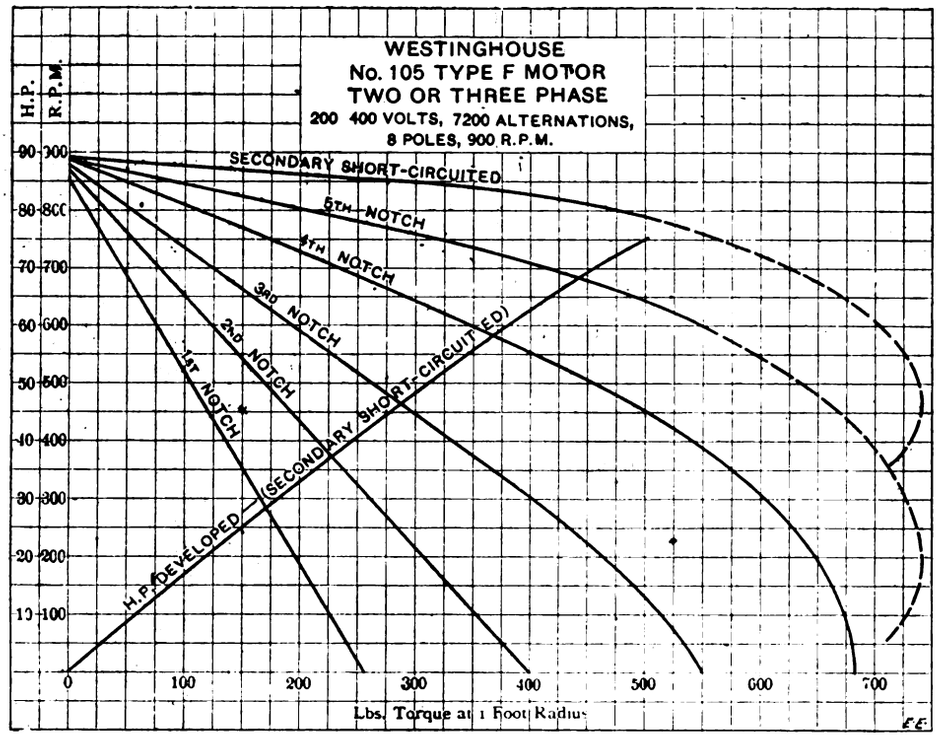

FIG. 4.

The E.M.F.'s generated in the secondary by the induction of the primary have to drive the currents through the secondary, not only against its resistance, but also against local E.M.F.'s due to the stray magnetic fields set up by the fields due to the primary and secondary currents being opposed to each other. These local E.M.F.'s due to magnetic leakage depend upon the frequency of the secondary currents, and vary with the drop in speed, reaching their highest value at zero speed, and cause a further drop in speed for any required torque. With large magnetic

the slip with a given torque is 5 per cent. it would be 10 per cent. if the secondary resistance was doubled, provided the primary voltage and frequency are kept constant.

The effects which different resistances in the secondary circuit have on the speed-torque curve may be considered as follows: Suppose in case (*a*) secondary resistance is small; (*b*) secondary resistance is doubled. The torque is the same in each case, but in case *b* the slip for a given torque is doubled. In case *c* secondary resistance is again

Digitized by Google

doubled, the starting torque is increased, but the slip is rather large, being double its value in case *b*. Case D slip is again doubled, which causes a large increase in the torque at starting, but it falls off rapidly as the speed increases. So far as a large starting torque is concerned, case D is the best for starting. For running, case A gives least drop in speed for a given increase in torque. From the point of view of primary current consumed, case A takes the largest current at start, but gives a low torque. Case B takes less current than A and gives a higher torque. Case C takes less current than *b*. Case D takes less current than C, and gives a maximum torque at the start. It will therefore be seen that when a resistance is introduced into the secondary circuit, each value of the resistance will have its own particular speed curve.

In Fig. 4 is shown a series of speed-torque curves, corresponding to different secondary resistances, of a Westinghouse variable-speed induction motor, and it will be seen that the speed at any torque given by any particular value of controller resistance is smaller than when the controller resistance is cut out and the secondary short-circuited. When this motor is run with a resistance in the secondary and develops a definite torque, the horse-power output will vary directly as the speed. The power factor, current, and power taken by the motor depend upon the torque developed, and are practically the same, independent of the speed, and the torque developed at any given slip is proportional to the square of the impressed E.M.F.

*(To be continued.)*

## STREET-LIGHTING IN THE CITY OF LONDON.

As was announced in our issue of last week, the Court of Common Council have decided to experiment on a large scale on the replacement of electric street-lighting by incandescent gas lamps. From the report of the Streets Committee we take the following figures as to the streets in which this experimental gas lighting is to be carried out:

| Street and new light. | Initial cost. | Annual saving. |
|---|---|---|
| Queen Victoria-street and part of Queen-street (45 high-pressure gas lamps)..... | £1,376 5 0 | £224 0 0 |
| Fleet-street (34 incandescent gas lamps)..... | 120 0 0 | 111 0 0 |
| Lower Thames-street, from Fish-street-hill to Billingsgate and Monument-street (33 high-pressure incandescent gas lamps) ... | 446 0 0 | 28 11 0 |

In these three streets the number of arc lamps now in use are respectively 27, 12, and 8.

It will be seen from these figures that a considerable outlay is to be incurred in order to secure a comparatively small annual saving. For instance, in the case of Queen Victoria-street the annual saving is only 16 4 per cent. on the first cost of installation. This leaves only a small percentage for depreciation after interest and sinking fund charges have been met. It is, however, with the general question of gas *versus* electricity for street-lighting that we have to deal, and we propose to show that the conditions in the city of London are exceptional, and that the comparisons made by the common councillors were unfair to the electric light. In the first place, any comparison of cost is quite valueless unless the cost is expressed as a function of the illumination produced It is even then most unfair to compare this figure for the new high-pressure gas lamps with that for the existing arc lamps in the City.

To make this point clear it is necessary to consider the past history of the street-lighting contracts. When the City of London Electric Lighting Company was formed, contracts were taken over under which a charge of £26 per annum was the agreed price for arc lamps to be supplied and maintained by the company. These arc lamps have to be kept alight from one hour after sunset to one hour before sunrise. Under the agreement also the company was bound to keep a separate plant for street-lighting, so that that portion only of their undertaking might, if desired, be separately acquired by the Corporation. In the early part of 1891, when this agreement was entered into, the price charged—*i.e.*, £26—per arc lamp was considered low, and the agreement was looked upon as a concession to the Corporation. We may also say that at the time when the present lamps were erected they were as good as any that could be obtained in the market. Unfortunately, litigation occurred over the company's concessions, and it was finally ruled by the House of Lords on Aug. 8, 1903, that two out of the three agreements held by the company were invalidated because certain of the common councillors who had voted for these held shares in the pioneer company. Since that date the street-lighting has been continued as though these two agreements were in force, and at the same price and subject to the same fines for any defects in the working of the lamps. Under the circumstances it is not a matter of surprise that the company have not replaced the arc lamps, which are now quite out of date, with others which would have rendered the present experiment with gas unnecessary.

This fact is partially admitted by the Streets Committee by the fact that they have asked for prices for electric lighting with new lamps. They have also been advised by their electrical inspector that the street-lighting could be done more cheaply with modern arc lamps than by gas. It was at the end of March that the subject of improving the electric lighting was first broached. Both the companies supplying electricity were then written to and asked for a quotation for an improved system of street-lighting. When, however, the Streets Committee were asked for more details as to what was required, the companies were informed that the electrical engineer of the Corporation was preparing a specification for the improved arc lighting, which would be forwarded in due course. This communication passed at the end of April. It seems curious, therefore, that without waiting for this specification to be issued, or for the tenders from the two companies in question, the councillors should have decided last week to spend nearly £2,000 in experimenting on gas lighting. The decision to do so must obviously have been arrived at without any comparative figures of costs, as it is absurd to compare old rates for electric lighting with the charges for a new system of incandescent gas lighting. It remains to be seen how far the real motive in the present movement is a desire to get the cheapest illuminant, and how far its object is to determine the present contract or contracts for the electric lighting of the streets. It will be obvious from the above that the decision come to last week has no bearing on the comparative merits of the two illuminants. Unless this is made clear to the councillors in other towns, it may lead others to a wrong conclusion on the street-lighting question. As to the actual cost with the two systems, reliable figures can be obtained from the quarterly reports of the city engineer of Westminster (Mr. J. W. Bradley) on street-lighting. These reports clearly show from trials in the streets extending over two or three years that the arc light is the cheapest illuminant when all the factors entering into the cost are considered. Even then the arc lighting at Westminster is not carried out with lamps of the most modern flame type. If a comparison is needed between the two rival systems as far as lighting is concerned, it can be obtained by a visit to the Mansion House-circus, where there are a few arc lamps of the flame type erected on the old lamp columns. We trust that the Corporation when spending some £2,000 on experimental gas lighting will also vote the much smaller sum which would enable the arc lighting in Queen Victoria-street, Fleet-street, and Lower Thames-street to be brought up to date. If this is done, we do not fear the result of the extensive competitive trials which would then be possible.

ELECTRICAL COMPANY'S PUBLICATIONS.—Recent publications issued by the Electrical Company, Limited, 121-125, Charing Cross-road, London, W.C., include three prints illustrating respectively three 75-kw. continuous-current generating sets driven by gas-engines at Limerick Corporation electricity works, two of four 240-kw. synchronous motor-generators supplied to the Corporation of Sunderland, and one of three 720-kw. three-phase alternators supplied to the same Corporation; also a leaflet describing the advertising twinkling socket already noticed in our columns, a pamphlet entitled "How to make Electric Light Cheaper than Incandescent Gas," and another on "Electrically-Driven Winding Engines," which we hope to make the subject of a separate notice in an early issue.

## THE CITY AND ELECTRIC LIGHTING.

There is jubilation in the streets of Ascalon—otherwise among those interested in the gas industry, and, like many another jubilation, seems warranted till fully investigated. The City Fathers, true to the versatility that has attended most of their dealings with electrical matters, have made another change. There is a lost art in modern civilisation—the art of remembrance. Memory now has reached its limits if it has extended over the space of nine days, and to extend over that limited period of time it must be exercised on something of the nature of the weird or the wonderful. The history of the City's connection with electrical matters is such a reiteration of change and shuffle that few retain the faintest perception of it. The early history is a case of "first she would and then she wouldn't"—procrastination and change through several revolving years. Then all seemed settled, agreements were made, but subsequently some of these agreements were held legally to be illegal. Meanwhile the lighting of certain streets was *un fait accompli*, and till now has continued as if the agreements were valid and in force. No one cared to test the matter of removal, and what was continued to be. The lapse of time and the march of improvements rendered possible both in electric and in gas lighting better things than existed when the original arc lamps were installed to replace the older form of gas lamps.

At the present moment we have not the slightest evidence that the City Fathers have made the comparison of improved electric lamps with improved gas lamps. All the evidence we possess is to the effect that comparison has been made of the best modern gas systems with the old, antiquated, out-of-date electric lamps, and it is to this comparison that all published figures relate. We ask if that is the position to be taken by those who control the affairs of the first city in the Empire? We ask if the men who do such a thing can have the faintest conception of business matters? And when we are told they are among the chief business men in the city of London, we open our eyes in wonderment. If what we have suggested above is correct, there is absolutely no moral to be drawn in favour of gas if this replacement be carried out, unless it be an unsatisfactory one. The position, to say the least of it, is peculiar. Negotiations were commenced with the electric light authority, and it was understood a specification was to be issued upon which new prices could be tendered, but, so far as we can gather, no such specification was issued, and therefore no new tender could be made. To put forward an estimated annual saving is a most misleading process unless other information be given as well; and to put this forward when one part of the expenditure is in accord with an old agreement, and not necessarily in accord with what might be done at the present moment, is still worse.

We are far from saying that the present system of lighting is all that can be desired. It is not. Progress has been made, and the results of that progress should be utilised. But—and here is one of the greatest difficulties to be encountered—the conditions of the case have been such as practically prohibit the utilisation of more modern lamps. Assume an agreement made now, that agreement should not preclude the adoption of improvements, but rather attempt to accelerate them. Is it possible to have an agreement at once variable and binding—that is, binding as regards replacement and variable as regards apparatus and price? An improved piece of apparatus should mean decrease of cost, and should be adopted, the consumer getting a benefit, but an agreement should not be so stringent as to compel the use

Digitized by Google

over a term of years of a particular piece of apparatus which, while excellent at the time, might be soon superseded. The present proposal is to supersede seventy-four arc lamps by one hundred and twelve gas lamps, and, as our contemporary the *Journal of Gas Lighting, etc.*, puts it, saving "at present prices three hundred and sixty-three pounds a year." We have indicated that the facts are altogether different, and that the question of saving "over present prices" has not been considered—it is the new gas against the old electric. Hence the lesson our contemporary would have us learn is fallacious. It says: "Herein we have the application to the municipal service of a fundamental principle of modern industrial practice—the abandonment of the existing for the new, if the new can produce an economy showing upon the outlay involved a balance of profit." This principle is certainly not modern, and cannot truly be applied in this case. The comparisons should be made with equivalent modern developments, and if this be done electricity will not be found wanting.

## CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

### "STAND-BY CHARGES, ETC."

SIR,—With your permission I should like to comment further on two points which were raised at the discussion of my paper on Thursday. The first point—a very pertinent one—was raised, I think, by Mr. Sparks, and I regret to have overlooked it in replying. Mr. Sparks asked why, in column 2 of Table A, I had taken works cost at 0·7d., whereas in column 3 I had reduced it to 0 45d. The reason is that with a motor load which clashes with the lighting load we cannot get rid of "peak" conditions in the working of the plant, and my Fig. 7 and the tables on pp. 26 and 27 show that under such conditions the boiler and other stand-by losses will never attain their minimum.

On the other hand, with the "restricted hour" load superposed on the "interest-paying" motor and lighting loads, the "peak" is less prominent (in contrast to the valleys) on the daily load curve, and the generating charges are reduced *below* what they would be with the interest-paying motor load alone, and, of course, still further below those with the lighting load alone.

The "restricted hours'" system is, I understand, in use at St. Pancras, and also by the County of Durham Company. Perhaps Mr. Baynes or Mr. Esslemont, though unable to take part in the discussion, may be willing to give us, through your columns, some indication of its success in either place.

The other point on which I should like to make a few remarks is the question raised by Mr. Jeckell. The figures given us by Mr. Jeckell were most interesting, but, unfortunately for the electric motor, they prove my figure of one unit per B H.P. hour to be only too near the truth where the motor is a small one and is working at a quarter of its rated load. Your readers shall judge for themselves. The following figures were given us by Mr. Jeckell:

| | |
|---|---|
| Revenue derived from motors | £4,385 |
| Units sold for motors | 854,543 |

Hence

| | |
|---|---|
| Average price per unit | 1·23d. |
| Total H.P. of motors | 905 |
| Units sold per H.P. installed per annum | 944 |
| Average cost per H.P. installed per annum | £4. 16s. 10d. |
| Number of hours of working per annum | 2,500 |

$$\text{Hence cost per B.H.P. per hour} = \frac{£4{,}385 \times 240}{905 \text{ H.P.} \times 2{,}500 \text{ hours}} = 0{\cdot}46\text{d.}$$

$$\text{Now energy per B.H.P. per hour} = \frac{\text{pence per B H.P. hour}}{\text{pence per unit}} = \frac{0{\cdot}46}{1{\cdot}23} = 0{\cdot}38 \text{ unit per B.H.P.}$$

The above result looks very plausible, and none would welcome it more than the writer, but it goes against the principle of the conservation of energy. Where, then, is the "nigger"? Simply that, as pointed out in my reply, Mr. Jeckell multiplies the *rated* H P. of his motors by the hours of running, and calls this the B H.P. hours.

To get the B.H.P. hours *developed*, this figure should be multiplied by the ratio of the average H.P. developed to the rated H.P. of the motor.

For instance, at Coventry, units sold per H.P. installed per quarter = 236, whereas with my Class I. motor (see p. 3) units sold per H.P. installed and developed per quarter = 585. Hence

$$905 \text{ H.P. for } 2{,}500 \text{ hours} \times \frac{236}{585} \text{ units} = 913{,}000 \text{ B.H.P. hours,}$$

whereas Mr. Jeckell has taken 2,260,000 B.H.P. hours.

Hence, also, 0·38 unit per nominal H.P. hour $\times \frac{585}{236}$ = 0 94 unit per B.H.P. hour, which is near enough to my figure to suit most people.

With reference to my Table C, it may be some consolation to Mr. Jeckell to be able to inform the gasman that the 1·37d. there given represents the cost of four hours' working and not of one hour, because it refers to a motor working on the average at a quarter of its rated load (my Class II.).—Yours, etc., A. M. TAYLOR.

### DIVERSITY FACTOR.

SIR,—As this question of diversity factor is one of the greatest importance, and my extension of the ordinary meaning of load factor has evidently been misunderstood, I beg leave to further trespass on your columns.

Mr. Tapper's remarks, and more especially Mr. Arthur Wright's communicated remarks, bear out in a striking way my own deductions (p. 18 of paper). The Glasgow motors, we are told, develop 60 kw. occasionally. Hence, taking a one-hour cycle, the energy consumption with a 100 per cent. "load factor" (in the sense I have taken it) would be 60 units per car.

But we know that for each unit consumed on the car we ought to do a car mile. Therefore, if the "load factor" were 100 per cent., we should cover 60 miles in that hour. But it is found in practice that, including all stops, we only cover, say, eight miles per hour = 8 0 units.

Hence the load factor (over a one-hour cycle) is only $\frac{8}{60} \times 100$ per cent. = 13·3 per cent. And the diversity factor is the reciprocal of the load factor, or $\frac{60}{8} = 7{\cdot}5$, which is almost exactly what Messrs. Wright and Tapper make it.

Similarly, with very intermittent work, such as lifts, etc., the diversity factor may easily reach values of 10, 15, or even 20, but the load factor goes down in proportion.

In spite of this, as I have shown in my paper, the station load factor (over the same cycle) may be quite high, because it is the product of the (cyclic) load factor and the diversity factor.—Yours, etc., A. M. TAYLOR.

## PERSONAL.

The Right Hon. Lord George Hamilton, P.C., M.P., and Mr. William H. Brown have been elected directors of the Metropolitan District Railway Company.

Mr. Charles James Cater-Scott (chairman of the London and India Docks Company) has been elected a director and appointed chairman of the London United Tramways (1901), Limited, Mr. Charles T. Yerkes having resigned the chairmanship in order to enable him to devote more of his time to the Metropolitan District Railway Company. Mr. William H. Brown has also been elected a director of the London United Tramway Company.

The engineer and manager of the Wellington Electric Light and Power Company, Limited (Mr. G. S. Maben) is visiting England.

Mr. Hilliard Stephens, A.M.I.E.E., A.M.I.M.E., of 39, Victoria-street, has been appointed sole London agent for the Asphaltic Limestone Concrete Company, Limited, for the sale of bitumen, box compounds, and asphalt. Mr. Stephens has also been appointed agent to Messrs. A. and J. Main and Co., Limited, structural engineers, Glasgow and London.

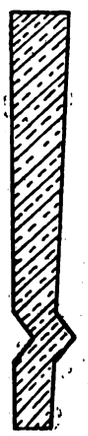
## INSTITUTION OF ELECTRICAL ENGINEERS.

### Students' Visit to Leeds.

The annual Easter excursion of the Students' Section of the Institution of Electrical Engineers was made this year to the Leeds district during the week May 1 to May 6. The journey down to Leeds was, however, broken at Loughborough in order to visit the Falcon Works of the Brush Electrical Engineering Company.

THE BRUSH ELECTRICAL ENGINEERING COMPANY.

As the manufactures of this firm are so well known in the electrical world, only a few notes of the most striking points of interest will be given. The company have under the Parsons patents perfected a type of steam-turbine which they are now making in several standard sizes. In the stationary field system of the turbo-dynamos a continuous iron surface is presented to the armature, as in the case of the stator of an induction motor. As is usual when this type of field magnet is adopted, compensating windings carrying the load current are placed across from one pole to the next so as to oppose the distorting action of the armature current, and thus facilitate sparkless commutation. In some machines a compressed stranded conductor has been used in the armature, and the commutator bars, besides being secured by the usual shrunk-on steel rings, are stamped (as shown in sketch) with small V niches, so that the bars are keyed, as



it were, into one another. With turbo-alternators the revolving-field type, again with a continuous iron surface, has been adopted, the magnetising coils being distributed over several slots, and the end bends securely held in slots cut in the massive brass end cheeks. Besides the above, the party saw under construction a 1,000-kw. inductor type alternator for the Leicester Corporation, a car body entirely of steel for the District Railway, and a 100-kw. transformer built especially for electric furnace work, giving on the secondary 12,500 amperes at eight volts. The controller and rheostat shop was also visited. The company in their controllers have adopted the multiple-coil type of magnetic blow-out, and for rheostats cast-iron grids are greatly used.

On Tuesday morning the party visited

THE LEEDS COPPER COMPANY'S WORKS AT HUNSLET

This company buys ordinary blister copper at a purity of about 96 per cent., and by refining and electrolysis turns out a pure material having properties both electrical and mechanical unobtainable, it is claimed, by any other mode of manufacture. The method of electrolytic refining is based upon the Elmore process, which has, however, been much improved and perfected by the present company. As the cost of power is of primary importance in the process, all the usual accessories have been installed in the power-house to attain an economical use of the fuel, which is a cheap small coal obtained from neighbouring collieries. In the engine-house four depositing sets of 170 kw. each have been installed, although two sets are sufficient for the works as they are at present. In this way a continuance of supply for depositing day and night is insured. The dynamos are of the Brown-Boveri make, and generate at 110 volts. They are belt-driven from Bollinkx cross-compound slow-speed engines. The first stage in the production of the electrolytic copper is the treatment in the refining furnaces, by which means all arsenic and many other impurities are removed, leaving 99½ per cent. pure copper, which is cast into triangular-shaped bars about 13ft. long to form anodes in the electrolytic bath. The second stage is the depositing. The electrolytic tubes are formed upon an iron mandril which has been thoroughly coated with blacklead. The cathodes are kept in continual rotation and are burnished by agate stones fixed in wooden clamps, these making one complete journey along the tank (a distance of 13ft.) every half-hour. When the deposit is completed it is removed from the iron mandril by placing in a lathe and "squeezing" the copper between friction rollers, after which the mandril is easily withdrawn on the draw bench. The copper tube is then annealed by heating to a dull red and quenching in a bath of dilute acid. It is then ready for drawing to any diameter and thickness in lengths up to 70ft. Before leaving the works all tubes are tested up to a pressure of 1,000lb. to the square inch, and for carrying out bursting tests a hydraulic intensifier has been installed giving pressures up to 26cwt. to the square inch.

Besides the manufacture of copper tubes by this process, the company also make a speciality of copper coatings on cast-iron cylinders, such as are used by calico printers and in hydraulic machinery of all kinds. They also manufacture drawn brass tubes in large quantities, but before passing to this part of the business, which does not involve the use of the electrolytic bath, a word must be said about that all-important part of the latter—namely, the electrolyte itself. The success of the depositing depends to a large extent upon the continual purity of the electrolyte, and in appreciating this fact the company have installed an up-to-date liquor shop in which the stale liquor is concentrated and a fresh and pure supply of copper sulphate crystals obtained. Owing to what we may call the "inefficiency" of the electrolytic bath, it is always found that the amount of copper *in the solution* grows as the solution is in use, so that there is a continual manufacture of copper sulphate. Further, because of the percentage of free acid used in the baths, it is found impossible to obtain good crystals from the liquor as it leaves the vats, so that before it is evaporated it is passed through a tank containing free copper, and into which hot air and steam are blown. In this way more copper sulphate is formed and the liquor loses its acid. It is then evaporated and led into cooling tanks, where pure copper sulphate crystals collect upon lead strips suspended in the liquor. The surplus copper sulphate crystals obtained as above form a valuable by-product.

Coming now to the manufacture of brass tubes, these are first cast in cast-iron moulds about 4ft. long, with cores made up of hay and loam pressed on to a metal shaft and baked. The cast tubes are then annealed by heating in a furnace and allowed to cool in air alone, not, as with copper, by quenching. They are then bored smooth in a special vertical machine, after which they are prepared for drawing in the same way as with the copper tubes.

As regards the mechanical properties attained by the electrolytic refining, we may state that the average maximum stress sustained by 12 samples taken at random from stock and tested by Mr. Thomas Nash, of Sheffield, was 17·4 tons per square inch, the numbers varying between 14·3 and 22·6. The figure given by Lineham as an average for ordinary copper is 13 tons per square inch.

On Tuesday afternoon the students visited the works of

MESSRS. GREENWOOD AND BATLEY, LIMITED.

This firm are the English licensees of the De Laval patents. The De Laval turbine with its helical reduction gear and its twin dynamos is too well known to require description here. Two sets have been installed in the power house and supply current for lighting and power, electric driving having been adopted throughout the works. Among the many manufactures of this firm, the one of chief interest was, perhaps, their electric brougham. It is equipped with a fairly small battery, capable of running the car 30 miles only, as the radius of travel of such a conveyance is, as a rule, not very

Digitized by Google

great. Two motors with double helical reduction gear are used, each motor having two armatures and two separate field windings. By this means a system of control is obtained in which a rheostat is only used on the first contact to cut down the initial rush of current. On the first and second control positions all the field windings and the armatures are in series, on the third position the field windings are first put in parallel, on the fourth position the armatures are put in parallel and the fields are both in series, whilst on the highest position the field windings are again placed in parallel. Another interesting feature is that the current is not broken on the copper contacts of the controller drum, but by a special carbon contact fitted with a magnetic blow-out device, actuated automatically from the controller drum. One reverse speed is provided, and the supply is shut off altogether by a plug which can only be inserted or withdrawn when the controller is in the stop position.

On Wednesday morning a visit was paid to the Midland Engine Works of

MESSRS. J. AND H. MCLAREN.

This firm makes a speciality of traction engines, more especially for agricultural purposes. Their engines for driving dynamos have a direct electrical interest. Electric driving has been, with a few exceptions, adopted throughout these works.

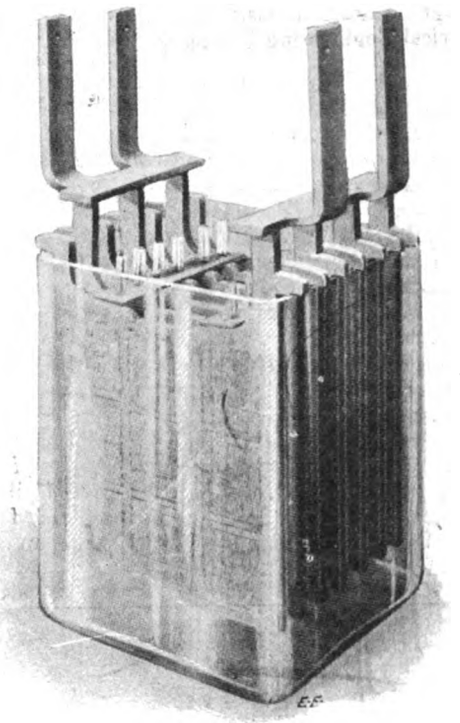
*(To be continued.)*

## THE BIJUR STORAGE BATTERY.

[COMMUNICATED]

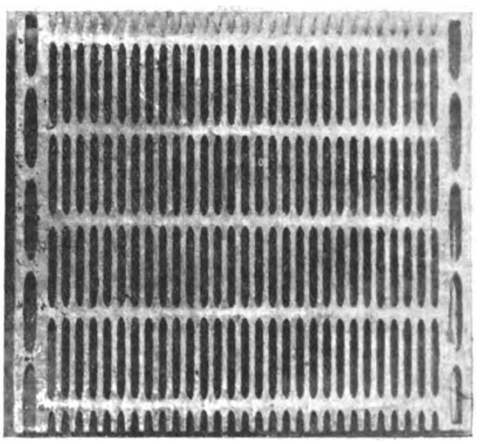
As a result of several years' work on the part of Mr. Joseph Bijur, of New York, a new form of storage battery plate has been produced, which, while retaining the well-tried electro-chemical combination of lead and sulphuric acid, differs radically in design, construction, and results from forms hitherto known in the storage battery art. With the collaboration of Dr. J. S. C. Wells, of Columbia University, in the earlier stages of the work, Mr. Bijur set out to produce a storage battery plate according to an ideal design which should be both mechanically and chemically perfect. This design embodied a rigid structure, freedom from tendency to distortion, perfect acid diffusion, active material incapable of being displaced, high specific capacity, high rates of charge and discharge, high efficiency, good regulation and freedom from "sulphation," buckling, or any other destructive action, save ordinary and unavoidable wear and tear. These characteristics could only exist in a form of plate made up of small, finely sub-divided structures, each free to expand unrestrainedly and firmly welded to a strong supporting and conducting grid. The active portions decided on as most advantageous could not be produced at commercial cost by any known method, whereupon Mr. Bijur set to work to produce these crudely, following this up by devising automatic machinery by which these parts are now made with great uniformity and at low cost. By no method of metal working then existing was it possible to commercially weld together two elements, of which one was a heavy solid form and the other of very fine thin parts. It was, therefore, necessary to devise a new method of metal welding which, after much patient work, in the face of seemingly insuperable difficulties was successfully accomplished, and for the carrying out of which on a commercial scale an entire line of machinery was constructed on original lines. The requisite quality and uniformity of oxide next received attention, with the result that, to secure the desired effects, a new process of formation was devised by which great toughness, porosity, and other desirable qualities could be imparted to the oxide layer, the whole process being perfectly reliable and at all times under the control of the operator.

The Bijur plates are composed of multiples of pure lead structures in the shape of gratings or "grills." These are welded to and in one piece with a stiff frame made of lead and antimony only. The weld goes clear through the plates, and is produced without the use of tin, solder flux, or any extraneous material whatsoever. The frame merges into the grill without joint. At each end of the grill a space is provided for its elongation by expansion, and provision is made for expansion sidewise. The result is a plate having the stiffness, strength, and inoxidisable support of the alloy grid, rigidly held active parts, yet complete provision for their expansion without the setting up of any strains that could produce buckling. The grills are composed of a multitude of minute openings or cells, open through from face to face. When in the untreated metallic



Bijur Storage Battery.

state these grills are very open structures, having a large number of component ribbons running in the vertical direction, supported by heavier cross members running horizontally, which serve as conductors, and give lateral stiffness. During the formation process, part of the metallic lead is converted into oxide, which, by reason of the large increase in volume, nearly fills the openings. The ribbons on the positive elements have a large amount of metal left as a reserve for the oxidation which is attendant on the normal action of every storage battery.



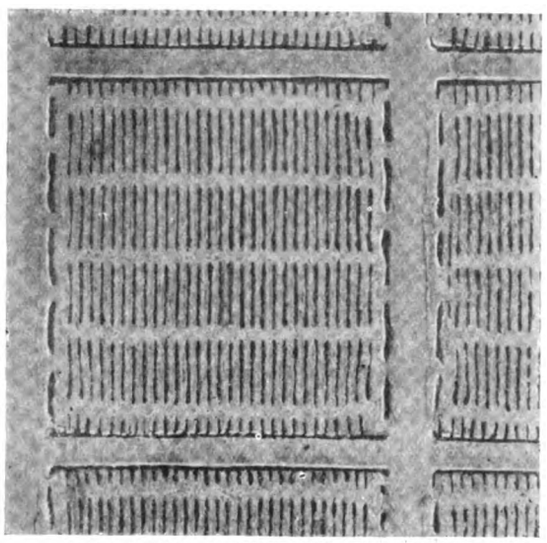
Grill "Unformed"—Bijur Storage Battery.

When the oxide is formed in the rectangular cells, it assumes a slightly elliptical shape, which, expanding into the rectangular containing space, produces a locking in that is so positive that nothing short of destruction of the plate can dislodge it. At the same time, even when the oxidation is carried to the point of apparently completely filling the cells, the tendency of the ellipse to grow larger along both its axes ensures the presence of a minute slot through the centre of the oxide mass, which allows the flow of electrolyte to take place freely through it. The resultant

Digitized by Google

oxidised plate, therefore, is rigid, the grills are firmly held, they expand without producing strains, each particle of oxide is firmly pressed against the lead from which it is grown, and the entire plate is open through and through to circulation and diffusion of the electrolyte. Owing to the character of the design and the structure of the oxide formed, the plates possess several features hitherto unattained in battery practice. "Buckling" cannot take place, and, so far, repeated attempts to intentionally produce distortion have failed. Also, since the perfect diffusion through the plate prevents high acid concentration in the pores, deleterious sulphation does not take place even when an effort is made to produce it.

One of the important advantages gained by this form of design, is that in a plate of given dimensions 20 per cent. greater capacity can be obtained with about 10 per cent. more reserve lead than in any form of plate hitherto constructed. The fine sub-division of the oxide into small masses, combined with the fact that the surfaces of the plates are composed of ribbon edge, precludes the possibility of blistering or shrinkage that is liable to occur when plates contain oxides in large masses. The makers claim that owing to the rapid acid diffusion full charge may be given the batteries at a voltage of 2·4 to 2 5 volts instead of 2 7 volts per cell, as is usually required. This low charging voltage results in increase of efficiency, and reduces the size of boosters required to charge. The structure of the plate forms a conducting network to all parts, ensuring equality of action all over its surface, and this, together with the facility for escape of gas without dislodging active material, favours the ability to stand very high rates of charge and overcharge without marked deterioration.



Section of "Formed" Plate—Bijur Storage Battery.

In short, since storage battery plates can be calculated out scientifically and then constructed in exact accordance with the design, the series of developments and inventions of Mr. Bijur places the manufacture of storage batteries on the same basis as that of dynamo-electric machinery. These processes permit of any suitable forms of active parts and supporting framework being united into one integral structure at a low cost of production and without the introduction of any foreign substances. Such being the case, an improvement in storage batteries may be expected similar to that which took place in dynamo construction after the laws of magnetic circuit and magnetic constants had been explained by Hopkinson, and applied by the engineering fraternity.

The General Storage Battery Company, which is now putting elements on this type on the market under the name of the Bijur "High-Duty" battery, has recently equipped a factory at Boonton, N.J., with special automatic machinery for the cheap and rapid production of storage batteries, where, by reason of an abundant and cheap hydraulic power and the automatic machinery used, storage batteries of the highest grade can be produced, it is claimed, for a lower cost per kilowatt-hour capacity than is possible anywhere else in the country. The company has also developed a new and complete line of automatic regulating boosters, end cell switches, and other auxiliary apparatus for all classes of central-station work and power plants, descriptions of which will appear later. It may be said, however, that all of these devices differ as radically from the present known types, as does the Bijur "High Duty" battery from the conventional storage battery electrodes, and the improvement in methods and degree of regulation represents a marked advance in storage battery engineering.

## TESLA PATENT ON WIRELESS TRANSMISSION OF ELECTRICAL SIGNALS.

An U.S.A. patent was issued on April 18 to Mr. Nikola Tesla for "The Art of Transmitting Electrical Energy through the Natural Mediums." We are indebted to the *Electrical World* for the abstract of this patent given below:

In the preamble it is stated that experiments and observations have tended to confirm the opinion held by the majority of scientific men, that the earth, owing to its immense extent, does not behave in the manner of a conductor of limited dimensions with respect to electrical disturbances, but much like a vast reservoir or ocean, which, while it may be locally disturbed by commotion of some kind, remains unresponsive and quiescent in a large part or as a whole. The inventor states he has discovered that notwithstanding its vast dimensions and contrary to all observations heretofore made, the terrestrial globe may in a large part or as a whole behave toward disturbances impressed upon it in the same manner as a conductor of limited size.

In the course of certain investigations he noted unsuspected behaviour of sensitive instruments, which he discovered to be due to the character of electrical waves produced in the earth by lightning discharges, and which had nodal regions following at definite distances the shifting source of the disturbances. From data obtained in a large number of observations on a maxima and minima of these waves, their length was found to vary approximately from 25m. to 70m., and these results and certain theoretical deductions led to the conclusion that waves of this kind may be propagated in all directions over the globe, and that they may be of still more widely differing lengths, the extreme limit being imposed by the physical dimensions and properties of the earth. By means of gradual improvements in the generation of electrical oscillations, electrical movements were finally reached not only approximating, but, as shown in many comparative tests and measurements, actually surpassing those of lightning discharges; and by means of this apparatus it was found possible to reproduce whenever desired phenomena in the earth the same or similar to those due to such discharges.

For example, by the use of such a generator of stationary waves and receiving apparatus properly placed and adjusted in any other locality, however remote, it is practicable to transmit intelligible signals or to control or actuate at will any one or all of such apparatus for many other important and valuable purposes, as for indicating wherever desired the correct time of an observatory, or for ascertaining the relative position of a body or distance of the same with reference to a given point, or for determining the course of a moving object, such as a vessel at sea, the distance traversed by the same or its speed, or for producing many other useful effects at a distance dependent on the intensity, wave-length, direction or velocity of movement, or other feature or property of disturbances of this character.

In the accompanying figure is represented diagrammatically the generator which produces stationary waves in the earth, and an apparatus situated in a remote locality for recording the effects of these waves. The generator consists of a primary coil forming part of a transformer and consisting generally of a few turns of a stout cable of inappreciable resistance, the ends of which are connected to the terminals of a source of powerful electrical oscillations, this generally being a condenser charged to a high potential and discharged in rapid succession through the primary. *C* is a spiral-wound secondary coil within the primary, one end being connected to ground and the other

Digitized by Google

to an elevated terminal, *E*. The resistance of the secondary system should be as small as practicable, its self-induction as large as possible, and the ground should be made with great care. The total length of the conductor from the ground-plate to the elevator terminal, *E*, should be equal to one-fourth of the wave-length of the electrical disturbance or to that length multiplied by an odd number. The relation being observed, the terminal, *E*, will be made to coincide with the points of maxima pressure in the secondary or excited circuit, and the greatest flow of electricity will take place in the same to permit free oscillation. The inductive connection between the primary and scondary should not be very intimate as in ordinary transformers, and this is accomplished by the spiral form given to coil *C*. With this arrangement it has been possible to produce an electrical movement thousands of times greater than the initial, and activity of rates of flow have been produced measured by many tens of thousands of horse-power. The powerful electrical oscillations being communicated to the ground cause corresponding vibrations to be propagated to distant parts of the globe, whence they are reflected, and by interference with the outgoing vibrations produce stationary waves, the crests and hollows of which lie in parallel circles, relative to which the ground-plate may be considered to be the pole—that is to say, the terrestrial conductor is tuned into resonance with the oscillations impressed upon it, just like a wire. A number of facts ascertained clearly show that the movements of electricity through the system follow certain laws

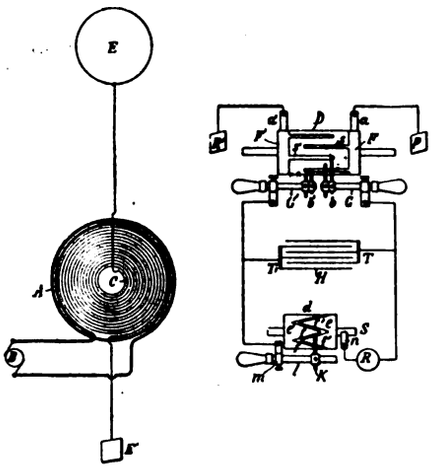


Diagram of Tesla Wireless Signal Apparatus.

with merely mathematical rigour. For the present it is sufficient to state that the planet behaves like a perfectly smooth or polished conductor of inappreciable resistance, with capacity and self-induction uniformly distributed along the axis of symmetry of wave propagation, and transmitting slow electrical oscillations without sensible distortion and attenuation.

Three additional requirements seem to be essential to the establishment of the resonant condition, as follows: First, the earth's diameter passing through the pole should be an odd multiple of the quarter wave-length—that is, of the ratio between the velocity of light and four times the frequency of the currents. Second, the frequency should be smaller than 20,000 per second. The lowest frequency would appear to be six per second, in which case there will be but one load at or near the ground-plate, and paradoxical as it may seem, the effect will increase with the distance, and will be greatest in a region diametrically opposite the transmitter. With oscillations still slower, the earth, strictly speaking, will not resonate, but simply acts as a capacity, and the variations of potential will be more or less uniform over its entire surface. Third, the main essential requirement is that, irrespective of frequency, the wave train will continue for a certain interval of time, which is estimated at not less than one-twelfth, or 0 08484 of a second, and which is taken in passing to and returning from the region diametrically opposite the pole over the earth's surface with a mean velocity of about 471,240 km. per second.

Fig. 2 shows a device for detecting the presence of the waves. It consists of a cylinder, *D*, of insulating material, which is moved at a uniform rate of speed by clockwork and other suitable motor power, and is provided with two metal rings, *F F*, upon which bear brushes, *A A'*, connected to terminal plates. From the rings, *F F*, extend narrow metallic segments, *S S'*, which by rotation of the cylinder, *D*, are brought alternately into contact with double brushes, *b b'*, carried by and in contact with conducting holders, *H H'*, supported in the metal bearings, *G G'*. The latter are connected to the terminals, *T T'*, of a condenser, *H*, and are capable of angular displacement as ordinary brush supports. The object of two brushes in the holder is to vary at will the duration of the electrical contact with the terminal plates and the condenser. To the latter is connected a receiver, *R*, and a device, *d*, performing the duty of closing the receiving circuit at predetermined intervals of time, and charging the restored energy through the receiver.

The receiver consists of a cylinder made partly of conducting and partly of insulating material, which is rotated at a desired rate of speed by any suitable means. The conducting part, *e*, is in electrical connection with the shaft, *S*, upon which slides a brush, *K*, capable of longitudinal adjustment in the metallic support, *m*. Another brush, *n*, is arranged to bear upon a shaft, *S*. It will be seen that whenever one of the segments, *F*, comes in contact with the brush, *K*, the circuit, including the receiver, *R*, is completed, and the condenser discharged through the same. By suitable adjustment the circuit may be made to open and close in rapid succession and remain open or closed during such intervals of time as may be necessary.

The terminal plates, *P P'*, through which the electrical energy is conveyed to the brushes, *A A'*, may be at a considerable distance from each other in the ground or one in the ground and the other in the air, preferably at some height. In the latter case the location of the apparatus must be determined with reference to the position of the stationary waves. If both plates be connected to earth, the points of connection must be selected with reference to the differences of potential which it is desired to secure. In receiving the speed of rotation of the cylinder, *D*, is varied until it is in synchronism with the alternate impulses of the distant generator; the brushes being properly adjusted, electrical charges of the same sign will be conveyed to each of the terminals of the condenser, and with each fresh impulse it will be charged to a higher potential. In this manner the energy of any number of separate impulses may be accumulated and discharged through the receiver, *R*. Thus a relatively great amount of energy may be accumulated and the receiver need not be very sensitive. It being possible to shift the nodal and ventral regions of the waves at will from the sending station, the regions of maximum and minimum effect may be made to coincide with any receiving station or stations.

By impressing upon the earth two or more oscillations of different wave-length, a resonant stationary wave may be made to travel slowly over the globe. If the nodal and ventral regions are maintained in a fixed position, the speed of a vessel carrying receiving apparatus may be exactly computed from observations of the maximum and minimum regions successively traversed. In any region at the surface the wave-length can be ascertained from certain rules of geometry, and, conversely, knowing the wave-length, the distance from the source can be readily calculated. Thus the distance of one point from another, the altitude and longitude, the hour, etc., may be obtained from the observation of such stationary waves. With several generators, preferably generating different wave-lengths, installed in selected localities, the entire globe could be sub-divided in different zones of electrical activity, and important data could be at once obtained by similar calculations or readings from suitably graduated instruments.

"EXCELLO" ARC LAMPS.—The Union Electric Company, Limited, 151, Queen Victoria-street, London, E.C., have just issued a new descriptive pamphlet and price-list of their "Excello" arc lamps. We have several times referred to the excellent results obtained with this type of lamp, and the comprehensive description of its properties and advantages now published should prove welcome.

## TRADE NOTICES AND NOVELTIES.

### Nodon Rectifiers.

A new pamphlet on the "Nodon" patent electric valve has been issued by Mr. H. Snowdon, Balfour House, Finsbury-pavement, London, E.C. This valve has been designed to transform alternating current into continuous current without the aid of moving machinery, its action being electrolytic. The results of some independent tests of the apparatus are included.

### The "Telaupad."

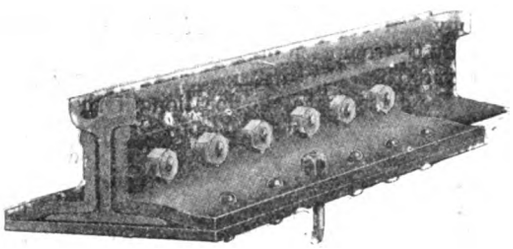
Some particulars are to hand of the "telaupad" or receiver cushion, a mechanical invention of British manufacture introduced by the Telaupad Syndicate, Limited, 10, Coleman-street, London, E.C., for overcoming the objectionable super-resonance and excessive buzzing noise so annoying to users of the telephone. The telaupad is a simple pneumatic contrivance which can be attached to the receiver in a few seconds, and has already been largely adopted.

### Impact Testing Machine.

Messrs. W. and T. Avery, Limited, Soho Foundry, Birmingham, have sent us a description of their patent Impact testing machine for testing material required to stand "shock." The principle of the apparatus is very simple. A pendulum weight is raised to a certain height and allowed to swing and strike the test piece, fracturing it in one blow, and the number of foot-pounds of energy which the test piece has absorbed is automatically registered on the indicating quadrant.

### Booth's Rail Joint.

We illustrate herewith a rail joint, chair, and sleeper combined, which has been patented by Mr. H. Booth, 84, Parkside-road, Sheffield. It is claimed that this joint ensures increased grip to head of rails when cars are passing over it,



gives double the ordinary bearing surface where most needed, and freedom from vibratory shocks, jolting, or hammering, and is cheap to construct. The joint is to be tried, we understand, by the Sheffield Corporation.

### Return-Current Circuit Breaker.

Messrs. Ernest F. Moy, Limited, Greenland-place, Camden Town, London, N.W., are introducing a return-current single-pole circuit breaker for continuous-current circuits up to 600 volts. This breaker is arranged to open on an actual reversal of current only. It will not open on "no current" or on any overload, and as its action is quite independent of 'bus-bar pressure it may be relied upon to disconnect a faulty generator at a definite return current of 20 per cent. of its rated capacity, although the station pressure may have fallen considerably. Illustrated particulars of its construction are contained in a circular just issued by the makers.

### Catalogues Received.

ELECTRICAL DRILLS AND GRINDERS.—A pamphlet which we have received from the Cincinnati Electrical Tool Company, Cincinnati, Ohio, U.S.A., contains illustrations and particulars of this firm's portable electrical drills and grinders for direct current.

LIGHT RAILWAY ROLLING-STOCK.—From Messrs. Dick, Kerr, and Co., Limited, Abchurch-yard, Cannon-street, London, E.C., we have received a copy of their latest work on light railway rolling-stock engineering. This contains illustrations and particulars of a large variety of tipping and other wagons, small steam locomotives, etc., for portable and light railways.

CELLS AND CARBON BRUSHES.—A number of illustrated circulars are to hand from the Atlas Carbon and Battery Company, Limited, Ewer-street, Union-street, London, S.E. They deal respectively with the firm's "Dania" dry cells for motorcars, etc., "Atlas" perfect porous pots for Leclanché batteries, "Atlas" carbon brushes, and the "Atlas" new central zinc battery.

SWITCHBOARD APPARATUS.—A postcard from Messrs. Cecil Hodges and Co., Balfour House, Finsbury-pavement, London, E.C., illustrates their central-station type of moving-coil instrument and a heavy traction switch. We understand the firm have a large amount of work in hand, including the switchboard for the King's Sanatorium in Sussex.

## STEPNEY ELECTRICITY ACCOUNTS.

The following is an abstract of the electric lighting revenue account for the 12 months ended March 31, 1905, taken from the accounts just issued by the metropolitan borough of Stepney.

| Dr. REVENUE ACCOUNT. | £ | s. | d. |
|---|---|---|---|
| Fuel, oil, waste, water, and stores | 8,729 | 10 | 1 |
| Wages at generating station | 1,768 | 18 | 6 |
| Repairs and maintenance of buildings and plant | 841 | 11 | 1 |
| Distribution of electricity | 752 | 16 | 11 |
| Attending and repairs to public lamps | 1,619 | 5 | 6 |
| Rates and taxes | 1,073 | 19 | 3 |
| Management expenses, salaries, etc. | 2,159 | 14 | 3 |
| Legal expenses | 239 | 8 | 2 |
| Special charges—insurance, etc. | 98 | 15 | 6 |
| | 17,288 | 17 | 3 |
| Balance carried to net revenue account | 14,837 | 1 | 5 |
| | £32,125 | 18 | 8 |

| Cr. | £ | s. | d. |
|---|---|---|---|
| Sale of current for private lighting | 23,863 | 3 | 1 |
| Sale of current for public lighting and power | 6,276 | 3 | 1 |
| Rent of meters, etc., on consumers' premises | 243 | 6 | 8 |
| Profit on work done for customers | 13 | 9 | 6 |
| Attending and repairs to public lamps | 1,619 | 5 | 6 |
| Rents receivable | 110 | 10 | 10 |
| | £32,125 | 18 | 8 |

## FORTHCOMING EVENTS.

FRIDAY, MAY 12.

**Iron and Steel Institute.**—At 10.30 a.m., annual meeting continued; at 7 p.m., annual dinner at Hotel Cecil.

**Physical Society.**—At 8 p.m., "A Simple Method of Determining the Radiation Constant, suitable for a Laboratory Experiment," by Dr. A. D. Denning; "A Bolometer for the Absolute Measurement of Radiation," by Prof. H. L. Callendar; and "The Resistance of a Conductor the Measure of the Current Flowing through it," by Mr. W. A. Price.

SATURDAY, MAY 13.

**Birmingham Electric Club.**—At 7.30 p.m., "Cheap Electrica Energy for Power Purposes," by Mr. J. A. Jeckell (provisional).

**Junior Institution of Engineers.**—Visit to Dorking water, gas, and electricity works.

MONDAY, MAY 15.

**Society of Arts.**—At 8 p.m., Cantor lecture (I.) "The Uses of Electricity in Mines," by Mr. H. W. Ravenshaw.

WEDNESDAY, MAY 17.

**Royal Meteorological Society.**—At 4 p.m., "Measurement of Evaporation," by Mr. Richard Strachan, and "Logarithmic Slide-Rule for Reducing Readings of the Barometer to Sea-Level," by Mr. John Ball.

**Institution of Electrical Engineers (Students' Section).**—At 7.30 p.m. annual general meeting.

**Electro-Harmonic Society.**—At 4.30 p.m., annual general meeting (9*d*, Victoria-street).

THURSDAY, MAY 18.

**Royal Institution.**—At 5 p.m., "Flame," by Sir James Dewar.

**Faraday Society.**—At 8 p.m., "An Application to Electrolytes of the Hydrate Theory of Solutions," by Dr. T. M. Lowry.

SATURDAY, MAY 20.

**Rugby Engineering Society.**—Visit to the Lots-road power station at Chelsea.

**Incorporated Municipal Electrical Association.**—June 27-30, annual convention.

## APPOINTMENTS VACANT.

**Town Electrical Engineer,** Municipality of East London, South Africa. Salary, £500 per annum. Applications by May 18. See advertisement.

**Electricians** (2) with commercial knowledge. See advertisements.

**Assistant** to take charge under mains superintendent. Wages, 50s. per week. See advertisement.

**Assistant Engineer,** Middlesex County Asylum, Napsbury, St. Albans, Herts. Wages, 35s. weekly and house on the estate. Applications by May 20. See advertisement.

**Assistant Electrical Engineer,** Oban. Wages, £70. Applications by May 15.

**General Manager,** Johannesburg, £2,000; Station Engineer, £1,000, with house. Applications to Mordey and Dawbarn, 82, Victoria-street, Westminster.

**Shift Engineer,** Manchester. Wages, £150. Applications by May 22.

# THE ALTERNATING-CURRENT SERIES MOTOR.*

BY F. CREEDY, STUDENT.

*(Continued from page 635.)*

## COMMUTATION.

With the object of endeavouring to throw some light on the commutation of the alternating-current series motor, and the various other actions going on in it, a number of experiments relating to this subject were made with the aid of a Duddell high-frequency oscillograph, the curves being photographed on a falling plate. Many of the results shown below could obviously not be obtained on any instrument which records, not a single wave, but the mean of several. For instance, in the motor examined no two commutation curves are exactly alike. A number of experiments was first made by the author, in conjunction with Messrs. R. S Dahl and H. M. Lyons. In order to remedy some omissions in these, some further experiments were made later on by the author. As, during these experiments, the motor was fitted with very wide brushes, covering rather more than three segments, the experiments on commutation were repeated, as, owing to the long time of commutation, much better curves were obtained on the falling plate. In the discussion given below I have confined myself almost entirely to this latter series of experiments.

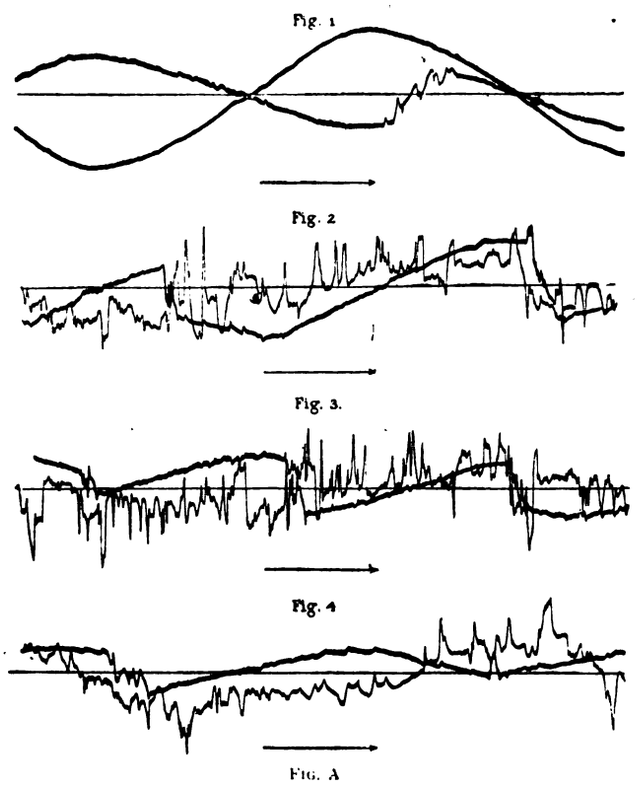

FIG. A

In observing the commutation curve of the motor the following method was made use of: the machine was fitted with two slip-rings, which were fixed on a piece of fibre and mounted on the commutator. One of these slip-rings was joined to a commutator segment, from which one of the armature connections had been unsoldered. This armature connection was then joined to the other slip-ring, and the brushes rubbing on these rings connected by means of a low resistance which served as a shunt for the oscillograph.

In Fig. A are shown a number of the commutation curves of the series motor obtained by the aid of this arrangement. Curve 1, consisting of a curve of main current and of current in the armature coil, contains a very good example of the kind of commutation curve which is found in this motor. As it was thought that the ripples in the current during commutation might be due to the irregularities in the E.M.F. induced in the short-circuited coil by the main flux, a search coil of one turn was wound round the pole-tip (as shown in Fig. 12) as near to the armature as was practicable. Since the brushes are on the neutral line, the E.M.F. induced in this coil, due to the variation of the main flux, will be nearly the same as that induced in the coil under the brush. Curves 2, 3, and 4 (Fig. A) show the current in the armature coil, and the E M.F. in the search coil parallel to it. Curve 2 was taken under the following conditions: main current, 20 amperes; speed, 1,000 revolutions per minute; frequency, $26\frac{2}{3}$ Curve 3 was taken under the same conditions, but at 2,000 revolutions per minute. Curve 4 was taken with main current, 17 amperes; speed, 1,000 revolutions per minute; frequency, 23. Resistance in circuit with the

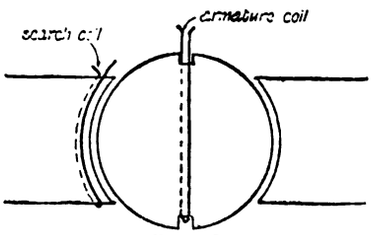

FIG. 12.

coil under observation = 0 3 ohms. In the first three curves shown the generator used was a Wenstrom rotary converter.

In order to eliminate any possible disturbance due to the slots, commutator, etc, of this machine, in Curve 4 and all those succeeding a bipolar Gramme machine, fitted with slip-rings and driven by a Westinghouse motor, was employed as generator. As this machine, of course, had a smooth ring armature, the effect of both slots and commutator were thus got rid of. Curve 4 was taken to show the effect, if any, on the shape of the commutation curve of putting resistance in the armature coil. As may be seen, there is no appreciable effect. These four curves, if examined closely, seem to give us the cause of the oscillation in the E.M.F. curve. In all of them we may notice that there are small ripples in the current curves. These ripples are bound to cause corresponding ones in the E.M.F. curves, and, in fact, we notice that there does exist a ripple in the current curve corresponding to each of the principal ripples in the E M.F. curve. This is especially marked in Curve 2. In order to show that very small ripples in a curve of current or flux are capable of producing enormous oscillations in the E M.F. curve, I give in Fig. 13 a curve of the E.M.F. induced in the search coil, and underneath it a curve which is the graph of the integral of the E M.F. curve, and is consequently proportional to the flux producing it. This curve was drawn by means of an integraph,

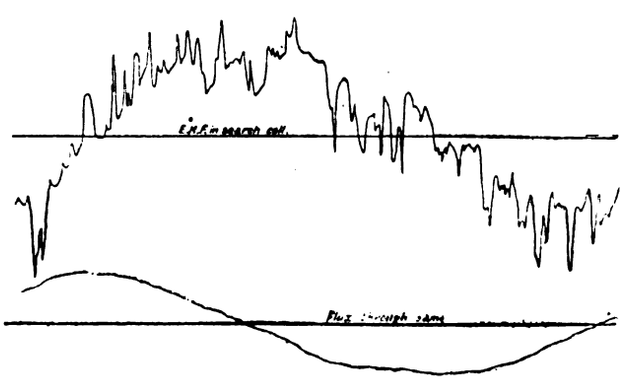

FIG. 13.

the use of which renders the drawing of these flux curves extremely easy, as it is only necessary to draw a point over the curve to be integrated, while a pen draws the integral curve. This method—viz, observing the E.M.F. in an oscillograph, and then integrating it mechanically—appears to be the only one by means of which curves of the instantaneous flux passing through a coil may be obtained.

The fact that the ripples in the current and E.M.F. curves do not in all cases exactly correspond is probably due to the fact that the current curves shown in Fig. A do not represent the total current flowing round the field, but merely that flowing through one coil of the armature. A

* Paper read before the Institution of Electrical Engineers.

Digitized by Google

difficulty in the way of the above explanation, I must admit, is caused by Curve 1. This does show the current which passes through the field, and it shows no sign of any ripple. But how account for the undubitable correspondence between the current and E.M.F. curves if we reject the above?

A curve of E.M.F. in the search coil and of armature current was also taken with a direct current through the motor. It showed the same irregular ripples in the E.M.F. curve. Thus these cannot be connected with the fact that the motor is an alternating-current one. Curve 4 also shows us another interesting point. One of the commutations in it takes place at the point where the current is zero. We see that as soon as commutation begins there is a sudden peak in the current, and this in spite of the fact there were 0·3 ohms in series with the coil under observation. I could reproduce, were it worth while, half a dozen different curves all showing this peak whenever commutation occurs while the current is zero. The cause of this is fairly obvious. If the current at all resembles a sine wave, its greatest rate of change occurs at the moment when it

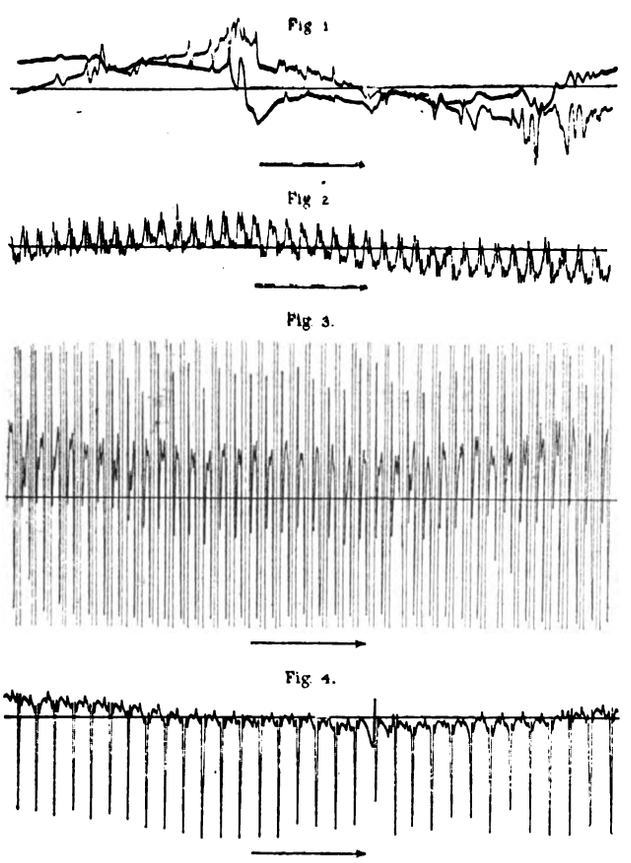

FIG B.

reverses, and consequently the E.M.F. induced in the short-circuited coil will be greatest at this moment.

From the nature of the ripples in the current curves they appear to be due to variations of the brush contact or some such cause. We should therefore expect that both they and the oscillations in the E.M.F. curve would disappear at standstill. This was tried and found to be the case, both being nearly sine curves. In order to make quite sure that the ripples in the E.M.F. wave were not due to the slots, the motor was driven externally and the brushes lifted. The E.M.F. curve was again found quite regular and devoid of ripples. The brushes were then put down, but were not connected to any external circuit. The result is shown in Curve 1, Fig. B. It may be seen that the peaks in the E.M.F. wave have reappeared, so that it seems as if some, at any rate, of the irregularity is due to the variation of the current in the short-circuited coil.

In order to endeavour to throw some further light on these variations, some experiments were made on a direct-current Westinghouse motor with laminated poles. A search coil of 13 turns was wound on the pole within $\frac{1}{8}$in. of the armature, and the E.M.F. in it was observed: (1) With the motor running light. The result is shown in Curve 2, Fig. B. It is, of course, very similar to that obtained by Dr. Thornton and described in his paper on "Eddy Currents." It contains a slow wave due to the eccentricity of the armature, which was very noticeable in this machine, and a ripple, due primarily, I think, to the slots. Most of these ripples have two peaks, though some have three. (2) With the motor running light, but the brushes moved over so as to produce heavy sparking. The same ripples are noticeable, but one of the hollows in each seems to be exaggerated into a peak of large amplitude in the other direction, while one of the peaks is correspondingly exaggerated. Thus the E.M.F. makes a complete alternation between the main parts of each ripple. (3) In order to find out whether the ripples in the two curves mentioned above are due to the slots or not, the Westinghouse motor was separately excited, run up to full speed, then shut down, the brushes lifted, and the plate taken while the motor continued to run on account of its inertia. The result is shown in Curve 4, Fig. B. The curve is very similar to Curve 2, but smaller. This is not due to a decrease of speed, for a comparison of the frequency of the ripples in the two cases shows that the speed was much the same in both. It still contains very sharp peaks, similar to those in Curve 3, but all on one side of the zero line.

Thus it would appear that the armature current in some way reinforces these ripples and also damps out the sharp peaks shown in Curve 4. A confirmation of this view may be found in the fact that Dr. Thornton found that these ripples were smaller (in fact, he could not observe them at all) when the brushes were in the neutral position than when they were displaced. This certainly suggests the reinforcement of the ripples by the armature current. This may, perhaps, be explained by the action of the armature current on the fringe issuing from the pole-tip.

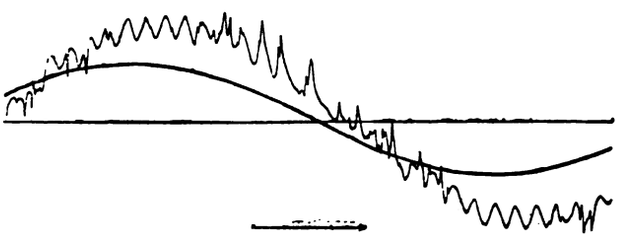

FIG. 14.

To sum up: The fact that we get the irregular-shaped E.M.F.'s shown in Fig. A with direct current as well as with alternating current, and that no such E.M.F. occurs in the Westinghouse motor, justifies us, I think, in inferring that it is peculiar to the motor experimented on. Moreover, the experiments described above definitely show that it is due to some action taking place at the commutator. It must be, I think, due to the fact that in order to get the current density in the brush low enough I was obliged to use brushes of very large area, and thus, the brush-holders being intended for much smaller brushes, the pressure was insufficient and the contact uncertain.

In Fig. 14 are shown curves of main current and counter E.M.F. in the series motor. The motor was driven externally, and the field excited with alternating current. This current and the E.M.F. across the brushes (which were open-circuited except for the oscillograph connections) were then observed on the oscillograph. These curves show very clearly that lag of the counter E.M.F. behind the current which I mentioned in Part 1. The ripples in the counter E.M.F. curve I am inclined to put down to the fact that the brush sometimes short-circuits three and sometimes four segments. When three only are short-circuited, there are more turns on the armature active than when four are short-circuited. When these curves were taken the motor was running approximately in synchronism, and it may be seen that there are about 36 ripples per period—the number of the slots and of the commutator segments. The above curves show something of the actions going on in an alternating-current series motor, but they afford no indication as to how to obtain good commutation. I found, however, that by using a very low current density in the brush, and moderately hard carbons (not too hard), I was able to get perfectly satis-

Digitized by Google

factory commutation in the motor I used with all frequencies up to 35, currents up to 30, and speeds up to 3,000. The irregular-shaped E.M.F.'s shown in Fig. A did not seem to affect the commutation.

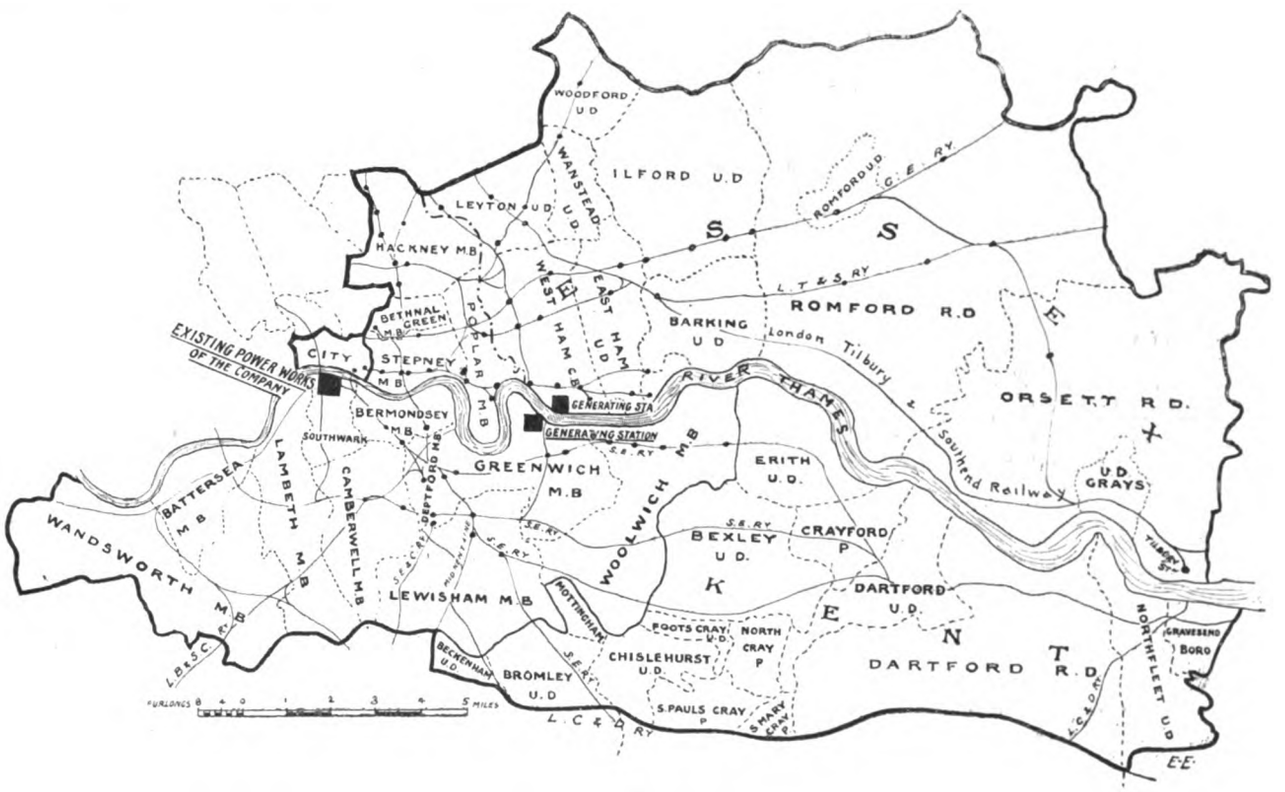
In conclusion, I wish to express my thanks to Prof. Ayrton and Mr. Mather, who have given me every possible assistance in carrying out the above series of experiments, to Mr. W. Cramp, and to the Crypto Works Company, the builders of the experimental motor. I wish also to express my thanks to those second and third year students of the Central Technical College who have assisted me in the above experiments, most of which required three observers. This assistance I have received from Messrs. Montgomrey, Halse, Austin, Webber, Hanson, Gordon, Deakin, Harper, Tanaka, and Strickland.

*(To be continued.)*

## LONDON POWER BILLS.

The committee of the House of Lords presided over by Lord Camperdown resumed on Tuesday the hearing of evidence on the nine Bills which have been promoted to deal with the supply of electric power in and around London. The two Bills now under consideration are the East London and Lower Thames Electric Power Bill and the City of London Electric Lighting Company (Extension of Powers) Bill. It was agreed to take these two as one measure, as they are both promoted by the City of London Electric Lighting Company. We give herewith a map to show the area over which powers are sought for the supply of electricity in bulk. It will be seen by comparing this with the map reproduced on p. 412 in our issue of March 24, that it is practically the industrial area in the Administrative County of London and District Electric Power Bill. The chief difference lies in the fact that Hampstead, St. Pancras, and East London are not included in the northern portion of the area. In introducing the Bill, Mr. Balfour Browne claimed that under the present scheme a supply of power could be quickly given and quite as economically as by the rival company. He explained that the company now had in their Bankside station plant capable of producing 22,000 kw. It was proposed to supplement this by installing at once five turbines of 5,000 kw. each and new boilers. The space at their disposal would enable 55,000 kw. of plant to be installed. The company also had scheduled areas for generating stations in West Ham and Greenwich respectively. He urged that the company ought to receive preference over one which had not previously done any work in the district. The company did not seek powers to compete with the existing companies, but wished to supply municipal undertakers in bulk.

Evidence was given by Mr. Frank Bailey on the engineering part of the scheme, and Mr. H. F. Parshall supported the same. He said from his knowledge of the station at Bankside the company could give an adequate supply of electricity more quickly and more cheaply than a new company could. Evidence was then brought to show the financial position of the company, and that it could promptly raise the extra capital required.



Map of the Proposed Area for Power Supply of the City of London Electric Lighting Company under their Extension of Powers Bill.

# LEGAL INTELLIGENCE.

## TELEPHONIC INTERCOMMUNICATION.

In the King's Bench Division last week Mr. Justice Buckley heard the action brought by the Swansea Corporation against the National Telephone Company, Limited, claiming a declaration that the defendants were bound to connect the telephone junction lines laid by the Corporation with the central switchboard in the National Company's exchange at Swansea.

Before a license was granted to the Corporation in 1902 to provide a system of public telephones in the Swansea area, the defendants worked a telephone system in the area, and their license was extended to 1920. The Corporation asked the defendant company to provide them with facilities for intercommunication; but differences arose between the parties as to the nature of the work to be carried out, and also as to how the costs were to be borne, defendants contending that the costs should be paid by the Corporation.

His Lordship held that the Corporation were entitled to relief. As this was the first case of the kind in the company's history, his Lordship said he would put his judgment into writing, and deliver it at a later date.

## TRAMCAR ACCIDENT.

At the Manchester Assizes last week, before Mr. Justice Bray and a common jury, the Salford Corporation were sued by Mrs. Esom for damages for personal injury.

The case for the plaintiff was that on Oct. 8, which was a Saturday, and a day on which a football match was being played, she, with a child, got upon a Salford Corporation tramcar at a "request" stop, to go to Weaste. She placed the child upon the step of the car and was getting on herself when, before she had obtained a secure footing, the car was started. She fell into the street, and suffered injuries for which she was medically attended.

It was admitted that in consequence of the football match the cars on that day were very crowded. Mrs. Esom said that before she got upon the car three passengers got off.

The case for the Corporation was that the car did not stop where the plaintiff joined it, but that it slowed down because there was

Digitized by Google

funeral procession in front of it. The plaintiff was anxious to get home, and he suggested that she thought the car was stopping, and mounted the step. He submitted that it had not been proved that the Corporation servants in charge of the car had been guilty of negligence.

The driver and guard stated that the car did not stop at the spot where the accident happened. No passengers left the car at that point. Similar evidence was given by an inspector.

A tramway inspector said the cars were very crowded at the time the accident happened. He had directed passengers to leave other cars, but he did not remove any passenger from this particular car. There were passengers on the step.

The plaintiff's counsel contended that if the Corporation of Salford made extra profits by carrying extra passengers, they must adopt increased safeguards to prevent overcrowding. It was clearly negligent conduct on the part of the Corporation if they placed themselves in the position of being overmastered by people who boarded the cars at the stopping-places.

The jury gave a verdict for the plaintiff, and awarded her £50 damages. The foreman said he had been requested by his fellows to say that in their opinion the Corporation had overcrowded the car, and had not taken proper precautions to protect the passengers.

Judgment was entered for £50 and costs.

# COMPANIES' MEETINGS AND REPORTS

## GREAT NORTHERN TELEGRAPH OF COPENHAGEN.

The general meeting of this Company was held at Copenhagen on the 29th ult.

Commodore E. SUENSON, the chairman and managing director, announced that the general state of the cables in 1904 has been satisfactory, although interruptions have been unusually frequent. The closing of the cables between Vladivostock and Nagasaki naturally rendered the Vladivostock route useless for all traffic between Europe and the Far East transiting Russia, but the Company has fortunately been able to substitute the alternative route *via* Peking-Kiachta-Irkutsk. The Russian Government has exercised no control whatever over the traffic transiting Russia, and will prevent accumulation of traffic in future by increasing the number of wires between St. Petersburg and Irkutsk. In order to accelerate the transmission over the Company's lines in Europe, not only of the above-mentioned traffic, but also of the whole Russian terminal traffic, the directors have, with the consent of the Imperial Government, established a service at the central station at St. Petersburg for direct working with Great Britain, Sweden, and Denmark, which has also benefited the transmission of telegrams between Russia and France. He then reviewed at length the position of matters in the Far East as affected by the Russo-Japanese campaign, which had naturally caused a dislocation of the commercial traffic, although the increase in the political and Press traffic has been enormous. However sad the causes which have created this huge traffic, financially the year has been unique in the annals of the Company. The directors were prepared for a decrease of £120,000 as a result of the considerable tariff reductions introduced by the London conference in 1903, and had the fortunes of war been different, the decrease would have been heavier still. Instead of this, however, traffic receipts have increased by more than £100,000, and, adding to this the profit from investments in other telegraph undertakings, etc., a total net revenue has been obtained which exceeds that of the hitherto most successful year, 1900, by about £28,900, although the expenditure has considerably increased on account of the expensive establishment at St. Petersburg, the maintenance of the third cable steamer, and the extra expenses necessitated by the transmission of the heavy traffic. Without having in the least altered their views of the position of the Company and its future as expressed in the reports of the preceding years, the directors are able, thanks to the unique results of the year under review, to propose the distribution of a dividend of 12½ per cent., together with a quite exceptional bonus of 11½ per cent., making in all 24 per cent., of which 5 per cent. has already been paid. In order to make this distribution to the shareholders, it has been necessary to place but a very moderate amount to the reserve and dividend equalisation funds. The latter has, however, also been credited with interest at the rate of 4 per cent., thus becoming a kind of savings fund for the benefit of the shareholders. It was proposed to increase by 50 per cent. the amount set aside for the pension fund of the staff, whose numbers have been increased in about the same proportion during the last five years. Dealing with the prolonged negotiations with the British and Danish Governments relating to the laying of the cable which is to connect the Faroe Islands and Iceland with the telegraph system of the world, he stated that, notwithstanding disappointments in regard to Government support, the directors have undertaken to carry it out before Oct. 1, 1906, conditionally upon the prolongation of the Anglo-Danish concessions of the Company until 1925.

## EASTERN EXTENSION, AUSTRALASIA, ETC., TELEGRAPH.

The half-yearly meeting of this Company was held last week under the presidency of Sir John Wolfe Barry. Particulars of the report appeared in our issue of the 28th ult.

The CHAIRMAN, after reviewing the financial position, alluded to references in the Press to a German-Dutch company, which was formed a short time ago under subsidies from the German and Dutch Governments for establishing German-Dutch cables in the Pacific Ocean and between the Netherlands, India, and China. The main object of this Company was to enable Germany and Holland to communicate with their possessions in the Far East independently of the British cables. The Eastern Extension, etc., Company had now come to a satisfactory working arrangement with the German-Dutch company, by which the interests of the former were safeguarded. The cable sections between the Celebes, the Carolines, and Guam, where the German-Dutch system joins the American cable systems, were laid last month, and the section between the Carolines and China is expected to be laid before the end of the current year. Regarding the Pacific Cable Conference, the directors understood that the long-deferred meeting of the Pacific Cable Conference may take place this month, when the effect upon the Pacific cable of the agreements entered into by certain of the Australian States with the Company and other questions arising out of the partnership will presumably be considered.

The Marquis of TWEEDDALE seconded the adoption of the report.

In reply to a shareholder, the CHAIRMAN stated that the reason why the directors did not propose a larger dividend was that they thought it prudent to build up a good reserve fund.

The report was then unanimously agreed to.

Sir A. J. L. Cappel and Sir J. D. Pender were re-elected directors, and a vote of thanks was unanimously accorded the directors.

## WOKING ELECTRIC SUPPLY.

The annual meeting of this Company was held at Woking, Mr. J. Ashby presiding. Particulars of the report appeared in our issue of the 28th ult.

The CHAIRMAN, in moving the adoption of the report, intimated that it was the policy of the Board to build up a solid reserve. The Board of Trade had just granted a provisional order for extending their operations to adjoining districts. As further plant was required the shareholders would be invited to subscribe to a fresh issue. He concluded by eulogising the work of the staff.

The report was unanimously adopted.

## KALGOORLIE ELECTRIC POWER.

The sixth ordinary general meeting of this Company was held last week at Winchester House under the presidency of Mr. Roger W. Wallace, K.C., the chairman of the Company. Particulars of the report appeared in our issue of the 28th ult.

The CHAIRMAN, in moving the adoption of the report and accounts, reviewed the financial position at length, and then outlined the prospects. They had made some favourable contracts during the past few months for the disposal of their power, and they had settled outstanding differences in the way of claims for not taking current. A rather difficult negotiation, which he had been conducting for some time, was with the tramway company, and they had now come to an agreement that was satisfactory to themselves and the tramway company, and he believed it would work well for both parties. The negotiations had been very arduous, and the result was practically this: that they charged the tramway company a fair price for the electricity, and, in conjunction with them, would manage the tramway lines, so that they could see that the electrical load was properly distributed. This would be of very great benefit to them in the working of the Company, as they would have exactly what was required from time to time for carrying out the work. There would be a joint committee of management for the working of the tramway, and this Company would receive the receipts and hand back to the tramway company their proportion of the takings. The arrangement was to run the tramways on a car-mile basis. Should the cost of the electricity delivered to them be cheaper, the tramway company would get 50 per cent. of the benefit, and this Company would get 50 per cent. A further result of this agreement was that practically the whole of their load was now taken up. The contracts, which would commence about August—many of which they had not had any benefit from at present—would make it necessary to consider how they could increase their plant. It would therefore not, in the future, be a question of utilising the plant they had, but of how much it should be increased.

The report was unanimously adopted.

## CALCUTTA ELECTRIC SUPPLY CORPORATION.

The eighth annual meeting was held last week at Salisbury House, Colonel A. J. Filgate presiding. Particulars of the report appeared in our issue of the 28th ult.

In moving the adoption of the report the CHAIRMAN stated that everything pointed to continued prosperity and to a growing business for a considerable time. The Company at the date of formation were granted a license for the supply of electricity under the Act of the Government of Bengal then in force, and they had had three new licenses granted to them for extensions of their area on the Calcutta side of the Hooghly. Since then a new Electricity Act had been passed by the Government of India. The Government officials suggested that it would be desirable to grant the Company a consolidated license under the new Act in supersession of their present licenses. A draft of the license which the Government were prepared to give them had been received, and, while it did not in any way damage them, in one important particular it placed them in a better position. The new license provided for the right to acquire their property at the end of the first 21 years on the same terms as the present licenses, and further provided the right to purchase on the same terms after the completion of each subsequent period of 10 years, so that the license would be a continuing one, and these new conditions were decidedly more favourable to the Company than those of the existing licenses.

The report was unanimously adopted.

A resolution was subsequently passed empowering the Board to arrange with the Government of Bengal and the Municipality of Calcutta and all other necessary authorities for the surrender of the

Digitized by Google

Company's existing licenses under the Indian Electricity Acts, and for the grant of a new license or licenses in exchange therefor.

## SOUTH STAFFORDSHIRE TRAMWAYS.

The report for the half-year ended Dec. 31 last, to be submitted at the meeting on the 22nd inst., states that the total revenue for the half-year amounted to £1,257. After deducting all expenses chargeable to revenue, there remains a profit of £653, which, added to the amount of £7 brought forward from the last account, gives an available balance of £670. The directors recommend a dividend of 1s. 8d. per share on the preference shares for the half-year, leaving to be carried forward £37. A settlement has now been arrived at with the South Staffordshire Tramways (Lessee) Company, Limited, with regard to the repayments for reconstruction under the terms of the lease, which is embodied in the draft agreement, and will be submitted for confirmation to the shareholders at the extraordinary general meeting to be held on the 22nd inst. The amount to be repaid for the work already carried out in respect of which that company claims £18,500 has been fixed at £11,500. Negotiations are still pending with the Corporation of Dudley regarding the purchase of the lines within their area.

## WELSBACH INCANDESCENT GAS.

The report for the year ended March 31 states that the net profit of the whole undertaking, including the dividend for the year 1903-1904 upon the Company's holding in the Austrian company, amounts (before deduction of debenture interest) to £94,010. To this has to be added £7,123 carried over from last year, making, in all, £101,134. With regard to the Company's investment in the Austrian company, the Board report that the serious difficulties in carrying out the arrangements for the separation of the "A" (gas) and "B" (electric) undertakings of the Austrian company, referred to at the last annual meeting, have been overcome, and that the necessary sanction of the Austrian Government to the separation has been obtained. As a result, Baron Auer von Welsbach has resumed the part interest in the osmium electric light which was vested in the "B" undertaking, the "B" shares have been formally cancelled, and the "B" undertaking as part of the Austrian company has ceased to exist. The whole control of the Austrian company is therefore now in the hands of the "A" shareholders. The past trading losses of the "B" undertaking have been repaid, with interest, and the Austrian company is under no future liability in connection with the osmium light.

## WESTERN TELEGRAPH.

The report for the half-year ended Dec. 31 states that the revenue amounted to £248,265, and the working expenses to £105,547. After providing for debenture interest and sinking fund and income tax there mains a balance of £123,831, to which is added the sum brought forward, making a total of £128,270. Interim dividends amounting to £62,379 have been paid, and after transferring £60,000 to the general reserve fund and £2,000 to the maintenance ships' reserve fund there remains a balance of £3,891, which is carried forward.

## NEW COMPANIES REGISTERED.

**Electro-Chemical Industries, Limited.**—Registered in Guernsey with a capital of £300,000. Object: to acquire and develop inventions, patent rights, etc., relating to electricity and chemistry.

### Liens Registered.

**Indian Electric Supply and Traction Company, Limited.**—A trust deed, dated April 20, 1905, securing £125,000 "construction" debenture stock has been registered. The company covenants, when Cawnpore undertaking is completed, to execute a mortgage thereof in favour of trustees in accordance with Indian law, with power to previously execute in England a charge on such undertaking, to be merged in the Indian mortgage when created. Trustees: F. L. Harris, M.P., 4, Green-street Park-lane, W.; and E. E. Bird, 58, Cadogan-place, S.W.

**South Metropolitan Electric Light and Power Company, Limited.**—Issue on April 18 of £15,000 debentures, part of a series created July 3, 1900, and May 16, 1904, to secure not more than the paid-up capital for the time being. Property charged: the company's undertaking and property, present and future, including uncalled capital. The debentures are issued to the trustees as further security for debenture stock covered by trust deeds of Aug. 3, 1900, and June, 1904. Trustees: H. R. Beeton, 18 Austinfriars, E.C.; and W. R. Davies, 10, Moorgate-street, E.C. Total amount previously issued of same series, £173,292.

**Electrolytic Alkali Company, Limited (Middlewich).**—Issue on April 13 of £3,150 debentures, part of a series created July 9, 1904, to secure £50,000, charged on the company's undertaking and property, including uncalled capital. Trustees: Liverpool Mortgage Insurance Company, Limited, 6, Castle-street, Liverpool. Total amount previously issued of same series, £17,500.

**Electric Ignition Company, Limited (Birmingham).**—A trust deed, dated April 10, 1905, and a debenture of even date, securing £2,000, have been registered. Property charged (by debenture): the company's undertaking and property, present and future, including uncalled capital, but excluding unissued capital. (By trust deed): manufactory and premises known as the Royal Wellington Works in Sampson-road, Birmingham, and the goodwill of the company's business. Holder: H. Lewis, Langleigh, Olton, Warwickshire. Trustees: F. Lewis and J. W. Lewis, Dominion Works, Upper Dean-street, Birmingham.

**W. T. Glover and Co., Limited.**—Issue on April 6 of £1,000 second mortgage debentures, part of a series created March 27, 1902, to secure £100,000, charged on the company's undertaking and property, present and future, including uncalled capital, subject to £100,000 first mortgage stock. No trustees. Total amount previously of same series, £99,000. A mortage or charge, dated April 6, 1905, to recover £16,100 (being, as to £1,000, part thereof an additional security with above-mentioned debentures), has been registered. Property charged: £80,000 second debentures (part of the said series of £100,000), issued to the Manchester and County Bank, Limited, and all moneys recoverable thereunder, subject to the rights of the said bank. Trustee: C. Cooper, 33, Princess-street, Manchester.

**Eastern Telegraph Company, Limited.**—A mortgage or charge, dated April 5, 1905, to secure £10,000 debenture stock, ranking *pari passu* with previous issues, amounting to £1,897,704, has been registered. Property charged: the company's undertaking and revenue. Holder: F. R. de Levanté, 141, Hill-street, Peckham, S.E.

## CONTRACTS FOR ELECTRICAL SUPPLIES.

**Tonbridge.**—The Urban District Council require tenders for cables. Tenders by May 29.

**Ashton-under-Lyne.**—The Corporation invite tenders for six tramcars. Tenders by May 23.

**Llandudno.**—The Corporation invite tenders for switchboard extensions. Tenders by May 22.

**Darlington.**—The Corporation invite tenders for two storage batteries. Tenders by May 23.

**Islington.**—The Borough Council require tenders for coal-conveyors, etc. Tenders by May 24.

**Dublin.**—The Port and Docks Board invite tenders for an electric generating station. Tenders by May 15.

**Cataquexes (Spain).**—The local light and power company require tenders for electrical plant. Tenders by July 1.

**St. Pancras.**—The Borough Council invite tenders for the supply of arc lamp carbons for 12 months. Tenders by May 23. See advertisement.

**Glasgow.**—The Trustees of the Clyde Navigation invite tenders for electric arc-light installation for the outer basin of Clydebank Dock. Tenders by May 22.

**Paris.**—The Colonial Office, 4 bis, Rue Jean-Nicot, require tenders for the supply of lamps and lighting accessories for three years. Tenders by May 23.

**Cork.**—The Electric Tramways and Lighting Company, Limited, invite tenders for the year's supply of electrical fittings. See advertisement in last issue.

**St. Marylebone.**—Tenders are invited for the annual supplies in the electricity department. Tenders by May 28. Full particulars in advertisement columns.

**Dartford.**—The Urban District Council invite tenders for the supply and erection of various plant. Tenders by May 24. See advertisement in last issue.

**Edinburgh.**—Tenders are invited for extension of switchboard panel at McDonald-road electricity supply station. Tenders by May 30. See advertisement.

**Cheltenham.**—The Corporation invite tenders for the supply of arc lamp carbons for the year ending March 31, 1906. Tenders by May 17. See advertisement in last issue.

**Leith.**—The Corporation invite tenders for coal elevating and conveying plant and boiler-house auxiliary plant. Tenders by May 17. See advertisement in last issue.

**Cork.**—The Cork Electric Tramways and Lighting Company, Limited, invite tenders for the supply of white wood casing and capping. See advertisement in last issue.

**Liria.**—The Municipality require tenders for installation of electric lighting; 2,000 c.p. are required for street-lighting, for which it is proposed to pay 6,000 pesetas per annum.

**Dax (Province of Landes, France).**—The Municipality require tenders for their concession to erect and work electric lighting for 35 years. Tenders to the Mayor by May 14.

**French West Africa.**—The Governor-General of French West Africa, at Dakar, requires tenders for the erection and equipment of a central station at that place. Tenders by May 15.

**Laventhem (Belgium).**—The Municipality require tenders for erection of central station, laying of mains, etc. Particulars (5s. 4d.) may be obtained from the Secretary of the Mayor of that place.

**Kettering.**—The Urban District Council invite tenders for the supply, delivery, and erection of Nernst lamps, posts, etc., for street-lighting within their district. Tenders by May 29. See advertisement in last issue.

**Burslem.**—The Corporation invite tenders for wiring the town hall, markets, baths, gymnasium, and Wedgwood Institute, and also for the supply of house service fuses and meters. Tenders by May 30. See advertisement.

**Stalybridge.**—The Stalybridge, Hyde, Mossley, and Dukinfield Tramway and Electricity Board require tenders for the supply, delivery and erection at the Stalybridge sub-station of a 400-kw. motor-generator, together with the necessary switchgear for same.

**Paisley.**—The Gas Corporation invite tenders for the following plant: (Contract 5) electric power generating plant, consisting o

Digitized by Google

gas-engines and dynamos; (Contract 6) elevated electric coke conveyors, electric screening plant, coke storage hoppers, etc. Tenders by May 13.

**Switzerland.**—M. R. Vontobel, of Winterthour, and M. Charles Probst, of Lucerne, have obtained a concession for the construction of a narrow-gauge electric railway from Meiringen to Gletsch. The total cost of the enterprise is estimated at £241,600; £19,600 is to be expended on rolling-stock.

**London.**—The London County Council invite tenders for the supply, erection at its generating station, East Greenwich, S.E., and maintenance for a period of 10 years, of a battery of 280 accumulator cells having capacities of 645 ampere-hours at a three-hour discharge rate and of 480 ampere-hours at a one-hour discharge rate. Tenders by May 16.

**Irvine (Scotland).**—The Corporation invite tenders for the supply and erection of the following plant: (Contract 1) buildings; (Contract 2) power-house plant—(Section A) suction gas plant, gas-engines, and generators; (B) balancers and boosters; (C) battery of accumulators; (D) switchboard; (E) crane; (Contract 3) mains—(Section A) cables, trenches, etc.; (B) converting street lamps; (C) meters. Tenders by May 15.

**Bangour (Scotland).**—The District Lunacy Board invite tenders for the following works: (1) building in boiler economisers, etc.; (2) building in chimney stalk; (3) building in steam and electric cable trenches; (4) steam boilers; (5) engines and dynamos; (6) economisers and piping; (7) overhead travelling cranes; (8) accumulators; (9) switchboard and connections; (10) main cables and branches. Tenders by May 27.

**London, S.E.**—The London County Council invite tenders for the road work and plate-laying required for the construction, for electrical traction on the conduit system, of certain authorised tramways in Blackwall-lane, East Greenwich, and from New Cross to Lewisham, and for the reconstruction, for the same system of electrical traction, of a portion of the existing horse tramways in Woolwich-road, and from Lewisham to Catford. Tenders by 10 a.m. on May 23.

**Heywood.**—The Council invite tenders for (A) Lancashire boiler, feed pump, hot-well, two water-filters, steam feed and blow-off pipes; (B) two 200-kw. steam dynamos, condenser, air and circulating pump, hot-well pump, water-cooling tower, exhaust and circulating pipes, oil separator and pumps; (C) traction switchboard, extensions to lighting board, cable connections, etc.; (D) traction feeders, telephone and test wires, switch pillars. Tenders by May 17. See advertisement in last issue.

## RESULTS OF TENDERS.

**Lowestoft.**—The Town Council have accepted the tender of W. J. Brooke and Co. for the supply of eight arc lamp posts at £10. 10s. each.

**Ramsgate.**—The tender of J. W. Woodhall and Son, Ramsgate, at £3,655, has been accepted for the construction of the new electric power station at Whitehall

**Govan.**—The tender of the Lancashire Dynamo and Motor Company, Trafford Park, Manchester, has been accepted for the supply of motors for all sizes above 3 h.p.

**Aberdeen.**—The Council have accepted the tender of W. H. Bailey and Co., Albion Works, Salford, Manchester, for the supply of one surface condenser, with air pump, oil separator, etc.

**Southampton.**—The Tramways Committee recommend the Council to accept the tender of Messrs. Griffiths, London, at £1,711, for relaying the Portswood-road section of the tramways.

**Bournemouth.**—The British Electric Equipment Company, 11, Queen Victoria street, E.C., have obtained the contract for the Christchurch tramways extension (overhead section) at £4,205.

**Bournemouth.**—The Town Council have accepted the tender of the British Electric Equipment Company, 11, Queen Victoria-street, E.C., at £4,315. 6s., for steel poles, overhead line, section boxes, etc., for the tramways.

**Cardiff.**—The Corporation have accepted the following tenders: British Westinghouse Company, main switchboard, £1,768. 4s.; Yates and Thom, pipes, £1,789; Horsfield and Co., superheaters, £442; General Electric Company, motor-generators, £4,955. 18s.

**Buenos Ayres.**—Messrs. J. G. White and Co., 22A, College-hill, Cannon-street, London, E.C., have been awarded the contract for the construction of the rural tramways. The work comprises supply and erection of 35 miles of overhead equipment, supplying and laying the necessary cables, supply of about 100 cars and equipments, and the erection and equipment of a power house with 2,000 kw. The amount of the contract is approximately £250,000.

**Mexborough.**—The National Electric Construction Company have secured the tramway contract for Mexborough, Rawmarsh, and Swinton. This contract includes the building of the generating station, car-sheds, generating plant, cars, permanent way, and cables; also feeders and distributors for lighting Swinton and Rawmarsh. The same firm have also secured the contract for the laying of permanent way, feeders, and cars for the Torquay tramways. Total amount in all approximate £300,000.

**Wigan.**—The Corporation have accepted the following tenders for (Section A) steam dynamo and accessories; (B) steam and water piping, ejector condenser, and motor-driven centrifugal pump; (C) paper and lead covered cables, dry-core telephone cables, paper and lead covered cables (twin service), and vulcanised rubber cables: (A) Dick, Kerr, and Co., Limited, Albert-square, Manchester, £3,695. 10s. (B) Tickle Bros., Vulcan Foundry, Wigan, £742. (C) Johnson and Phillips, Old Charlton, Kent, paper and service cables, £1,023 and £176; British Insulated and Helsby Cables, Limited, Blackfriars, Manchester, telephone cable £74, rubber cable £464.

**South Africa.**—The *British and South African Export Gazett* mentions the following contracts: The A.E.G. Electrical Company of South Africa have in hand an order for the auxiliary plant for the Pretoria electric installation. Two orders each for a 30-h.p. motor for the Village Deep and the New Modderfontein mines respectively have been placed with the British Westinghouse Electric and Manufacturing Company through C. C. George and Co., Johannesburg. Messrs. Ingram and Kemp, Birmingham, have in hand an order for the supply of electrical fittings for the new city hall, Cape Town. The contract for the supply of the electrical pumping machinery for the Kroonstad water-supply scheme has been given to Messrs. Hubert Davies and Spain, Johannesburg. A powerful electric lift has just been installed at the new premises of Mr. J. Garlick, Cape Town. The makers are R. Waygood and Co., London, S.E. Messrs. Hubert Davies and Spain, Johannesburg, have secured the concession for installing and working electric tramways at Bloemfontein, and will shortly be placing orders for the necessary machinery, etc. An order for an additional alternator for the King William's Town installation has been placed with the Electric Construction Company, and orders for four transformers have likewise been given out.

**Engines.**—Messrs. Browett, Lindley, and Co., Patricroft, report the following recent orders: Industrial Engineering Company, Limited, Hyde (for the Shelton Iron and Steel Company, Limited), one 150-kw. engine; Newport Corporation, one 300-kw. steam dynamo, also one 200-kw. steam balancer, including dynamos by the General Electric Company, Limited; Bruce Peebles and Co., Limited (for the Canadian Electric Tramways), one 250-kw. engine; the General Electric Company, Limited, the jet condensing plant for the King's Lynn Corporation; J. Birch and Co., London (for mill lighting in India), one 50-kw. set, including dynamo by J. P. Hall and Co., Limited; Witting, Eborall, and Co., London (for mill lighting in India), one 50-kw. engine; British Thomson-Houston Company, Limited (for the Hoylake Urban District Council's electricity works), one 250-kw. engine; J. H. Holmes and Co., Newcastle-on-Tyne (for Brookes and Doxey, Limited), a tandem compound engine; Fernhurst Spinning Company, Limited, Oldham, one 1,400-i.h.p. three-crank, triple-expansion vertical Corliss engine for driving their mill by ropes; Phœnix Dynamo Manufacturing Company, Limited, Bradford, one 300-kw. engine for the Keighley Corporation; one 85-kw. engine for coupling to a three-phase generator for a large Bradford mill; also an engine for coupling to a dynamo for the West Riding County Council.

# BUSINESS NOTES.

## TRACTION.

**Cheshunt.**—The tramway order is still under consideration by the Board of Trade with reference to proposed alterations in the financial clauses.

**Lancs. and Yorks Railway.**—A fire occurred last Saturday evening on one of the electric trains running between Liverpool and Southport, but no casualties occurred.

**Leeds.**—The Tramway Committee have decided to recommend the Council to allocate £55 000 of the tramway profits to the relief of the rates, as compared with £52,000 a year ago.

**Heywood.**—The terms given in our last week's issue for the running of cars between this town and Bury and Rochdale have been approved by the respective Tramways Committees.

**Maidstone-Headcorn.**—The enquiry into the project of a light railway between these places has been completed, but the Commissioners may visit the route again before giving their decision.

**Mansfield Light Railways.**—The Board of Trade have sanctioned an extension of time for six months for the construction of the lines authorised by the Mansfield and District light railways order.

**Folkestone.**—The Corporation have apparently decided that a sub-committee shall proceed with the negotiations with the Traction and Power Securities Company and Lord Radnor in reference to the construction of a tramway system.

**Edinburgh.**—Under the Private Legislation Procedure (Scotland) Act a provisional order has now been lodged by which it is sought to incorporate the Edinburgh Suburban Electric Tramways Company, empowering them to construct several electric lines.

**York.**—The local branch of the Independent Labour Party has issued a manifesto supporting the Corporation in the deadlock which has occurred in the negotiations between the Corporation and the company for the purchase of the latter's undertaking.

**Coventry Electric Tramway Co.**—The Hon. Arthur G. Brand, M.P., presided at the meeting of this company and moved the adoption of the report, which stated that the net earnings for the year were £3,410, being a decrease of £1,232 from the year 1902. The report was adopted.

**London United Tramways Co.**—The Unopposed Bills Committee of the House of Commons have passed the Bill of this company seeking an extension of two years in respect of the construction of tramways in Croydon and Wimbledon authorised under previous Acts. It had been found impossible to carry out the work in the limited time specified in those Acts.

**Lampeter-to-New Quay.**—The promoters of the proposed light railway to connect Lampeter, Aberayron, and New Quay are doing their utmost to secure the success of the project they have in hand, and at the next meeting of the Cardiganshire County Council a motion will be brought forward asking the County Council to grant a sum of £30.000 towards the project.

**Cape Electric Tramways.**—Another meeting of this company is to be held on the 23rd inst. It is a sequel to the gathering held some

Digitized by Google

little time back. At that meeting, it will be remembered, Mr. Parrish was removed from the Board after a poll had been taken. Mr. Parrish then intimated that he would requisition another meeting, so that the directors would have definite instructions from the shareholders not to buy or re-lease the Consolidated undertaking. The directors state that they are in entire accord with this resolution.

**Dundee.**—It is reported that a company is considering the question of starting a motor 'bus service in Dundee and district. The proposal is to run vehicles of the type so familiar in London. The route favoured in the first instance is towards the east, connecting the city with Broughty Ferry, Monifieth, and Carnoustie, and then probably Birkhill and several of the villages along Perth road. It is thought that the capital necessary to establish a rapid service in the Broughty direction would not be heavy—not more than about £12,000.

**London County Council.**—The Camberwell Borough Council has appointed the Mayor and Councillor A. T. Moore, with the town clerk and borough engineer, to give evidence in support of the County Council's Bill for carrying the trams over Blackfriars Bridge. The Borough Council have also decided to support the County Council in the latter's endeavour to obtain enlarged powers in reference to the laying of temporary rails. The Stepney Borough Council have also agreed to support the Council's scheme for carrying the trams over Blackfriars Bridge.

**Burton-on-Trent.**—The report relating to the tramways for the year ending March 31 last was issued at the meeting on Wednesday. The amount expended on capital account reached the sum of £86,012. 13s. 11d. The number of passengers carried was 3,878,269, and the traffic receipts per car mile were 9·21d. The maximum number of passengers carried any one day was 24,885, and the receipts £125. 4s. The gross revenue account for the year showed a surplus of income over expenditure of £5,160. 19s. 5d., of which £4,604. 0s. 7d. was absorbed in repayment of debt and interest, leaving a balance of £556. 18s. 10d., which it was proposed to carry to the repairs and renewal fund.

**Aberdeen.**—At the meeting of the Tramways Committee last week a letter was read from the Aberdeen Suburban Tramway Company intimating the acceptance of the Corporation's terms as to running powers for another year. It was resolved to lodge a petition against the Great North of Scotland Railway Company's provisional order for the running of motor 'buses in connection with their trains. The new Guild-street bridge having now been taken over by the Streets and Roads Committee, instruction was given that intimation should be made to the Board of Trade, requesting the inspector to go over the tramway line and pass it, with a view of traffic being commenced at as early a date as possible.

**Liverpool.**—We learn from Mr. C. R. Bellamy, the general manager of the Corporation tramways, that in the annual report for 1904 certain figures were transposed through a printer's error. The main items in this connection, correctly rendered, are as follows, the figures referring to 1902, 1903, and 1904 respectively: total capital expenditure to end of year, £1,832 977, £1,863 485, and £1,916 257; revenue, £517,935, £544,720, £557,888; operating costs, £339,810, £341,463, £367,845; percentage of operating costs to total revenue, 65 per cent., 62·6 per cent., 65·9 per cent.; gross profits, £178,124, £203,256, £190,043; interest and sinking fund, £102,627, £107,014; £108,717; balance, £75,497, £96,242, £54,217.

**Bury.**—The Corporation have adopted the following report of the Tramways Committee: "That the committee are of the opinion that it is desirable the existing tramways in Bolton-road should be extended along that road to the boundary of the borough of Bolton and of the township of Ainsworth, and therefore reques: the Council's instructions in the matter," and "that the Council be requested, in the event of their deciding to proceed with the Bolton-road extension, to direct whether or not powers shall at the same time be sought to extend the Fairfield section to the boundary of the borough of Bury on Rochdale Old-road, and also for the extension of the Limefield section to the boundary of the borough on Walmersley-road."

**Birmingham.**—An accident took place on Saturday morning on the Small Heath electric tram route. The trolley wire broke at the corner of Hill-street and Station-street, and in its fall it struck Frank Keisler, of 95, Coventry-road, Hay Hills, causing injuries which were subsequently treated at the Queen's Hospital. At the time of the accident an electric car was proceeding round the corner at the junction of Hurst-street, Hill-street, and Station-street. The upper deck of the car was well laden with passengers, and, as the terminus was near, all were preparing to get off. Keisler had, in fact, just stepped off the footboard when the wire snapped, and it caught him on the forehead, inflicting a wound over the left eye and an injury also to the nose.

**Bordeaux Tramways.**—The directors of the Compagnie Française des Tramways Electriques et Omnibus de Bordeaux have declared a dividend for the half-year ended Dec. 31, 1904, of 6fr. on registered shares by endorsement on certificate, and 5 85fr. on bearer shares against coupon No. 7. The company also announces that 211 shares have been drawn for repayment at 298fr. per share, the holders also receiving a dividend share (action de Jouissance). The registered certificates, coupons, and drawn shares can be deposited with the Comptoir National d'Escompte de Paris (London agency), 52, Threadneedle-street, E.C., for payment at the current rate of exchange of the day, where a list of the shares drawn for redemption can be seen on application.

**Gloucester.**—The first annual report of the Gloucester Light Railways Committee and an analytical statement of operating expenditure and income from April 29, 1904, to March 31, 1905, has been issued. The result of the 11 months' working shows that the revenue amounted to £13,908. 8s. 2d., and the operating expenses to £9,741. 14s. 11d., showing a gross profit of £4,166. 13s. 3d. to carry to net revenue account. The total receipts amount to 7·43d. per car mile and total operating charges to 5·20d. per car mile. The cars have run 449,320 miles and have carried 3,546,852 passengers during the 11 months, the traffic earnings per car mile being 7·22d. There were no serious casualties. The undertaking has taken energy to the extent of £2,831. 0s. 7d. from the electricity department of the Corporation, contributed to the rates £226. 18s. 5d., and effected a considerable saving in road maintenance.

**Glasgow.**—At the enquiry into the Corporation's Tramways Consolidation Bill, which seeks, among other things, power to extend the lines and to carry parcels, opposition was offered by the railway companies, who contended that if the Corporation were empowered to carry parcels, it would convert what had hitherto been a tramway into a light railway. The proposal to extend the Corporation system to Barrhead has been dropped. At a meeting of the Town Council, the convener of the Tramways Committee stated that negotiations with the County Council of Renfrew had been broken off. Decisions have been given in regard to several proposals for extensions of the Glasgow tramways. The Commissioners found that a case had not been made out for the extension of the system from Maryhill into the county of Dumbarton to Canniesburn, but they sanctioned the extension as far as Garscube Bridge, which is the municipal boundary. They also sanctioned two important extensions into Lanarkshire, on the east of the city, from Barrachnie to Baillieston, and from Tollcross to Uddingston.

**Aston.**—In submitting the report of the Public Works Committee Alderman W. Evans mentioned the steps which they were taking concerning the future working of the tramways. The committee had passed two resolutions, which they asked the Council to approve of. The first resolution read: "That the town clerk be instructed to make application to the City of Birmingham Tramways Company for a statement of accounts showing the result of the working of the tramways within the borough, the subject of the agreement of June 9, 1903." Alderman Evans added that they wished to see what the trading profit had been for the past year before they could be prepared to negotiate or to do anything with Birmingham. The second resolution was: "Resolved that a committee of three, consisting of the Mayor, Alderman Evans, and Alderman Smith, be deputed to see the B.E.T. Company with a view to ascertaining what arrangements they are prepared to make if the Council released them from the terms of their agreement of June 9, 1903, and also, if thought desirable, to see the Corporation of Birmingham and ascertain what terms that body are prepared to offer, if the Council would grant them a lease of their tramlines within the borough for a period of 21 years." This, remarked Alderman Evans, ought to satisfy everyone of them that the committee were doing all they could to bring about an amicable working arrangement with Birmingham in the interests of the people of Aston. The report was adopted.

**Belfast.**—At the meeting of the Tramways Committee last week a letter was read from the British Electric Traction Company as to the supply of current for the Cavehill and Whitewell tramways, stating that, having carefully considered the Corporation's offer, they were now prepared to take current from the Corporation at a flat rate of 1½d. per unit, and they wished to know at what time the current would be supplied. After some conversation between the electrical engineer and the members it was resolved that no alteration could be made in the conditions upon which the first offer had been tendered to the company. The next business was taken up, which was the surveyor's report in regard to the progress of the work of reconstruction. He stated that there were 14 miles of the track completed, five miles at present under construction, and several miles ready for traffic. The general manager, in his report, intimated that he had received a letter from the makers of the tramcars, from which he expected to have the first car in Belfast upon Thursday next. After that the cars would be delivered at the rate of so many every week, and the whole of them would be there by September next. In order that he might have a sufficient number to commence the full service, he asked permission to transform in their own workshops 50 of the old cars into electric cars, which would bring the total available up to 220. This was agreed to after some discussion. Mr. Nance reported that the track was now completed on the Shore-road and on the Lisburn-road as far as Balmoral, and it was intended to deal with the Malone-road immediately. A councillor suggested that a letter should be written to the National Telephone Company pointing out that the latter had not yet removed all the wires that must necessarily be removed along the tracks. In answer to questions, the electrical engineer said it would be most dangerous to run the electric cars where these telephone wires were allowed to remain. It was decided to write to the company.

**Plymouth.**—It is reported that friction has arisen between the Corporation and the Plymouth, Stonehouse, and Devonport Tramways Company. A few years ago the Corporation, under an agreement with the company, reconstructed and electrically equipped the tramway from Derry's Clock to the borough boundary at the Palace Theatre, and leased it to the company on payment of a rental calculated at 11 per cent. on the capital outlay. At that time the company had the sole use of the line, the Theatre Royal being the terminus for all the Corporation trams. Subsequently, however, the Corporation made the Palace Theatre the terminus for the Prince Rock cars, and more recently for the Peverell Park cars also. This has greatly increased the traffic over the Union-street line, and the company complain strongly of the inconvenience which has resulted to their service, and the unfairness of the competition they have now to meet. Under the agreement, the company take from the Corporation electric current for the working of their cars between Derry's Clock and the Palace Theatre, and they complain of the charge as excessive. Another matter of difference is the assessment of the tramway undertaking. In addition to the rental charge, the company have been called upon by the Corporation to pay the full rates on the property. While they had the exclusive use of the line the company paid the rates without question, but since the Corporation have been running their cars over the line the company have

Digitized by Google

objected to pay the rates, and considerable arrears, amounting to several hundred pounds, have accumulated. Efforts to arrive at an amicable settlement have not so far met with much success, and the Tramways Committee at a special meeting reviewed the whole position. It was reported to them that the Plymouth, Stonehouse, and Devonport Tramways Company had failed to make the payments due to the Corporation under Section 35 of the Plymouth, Stonehouse, and Devonport Tramways Act, 1900, within the time limited by the Act of Parliament, and the committee thereupon decided to recommend: "That notice in writing be given to the Plymouth, Stonehouse, and Devonport Company determining forthwith all the rights conferred on the company by Section 35 of the said Act, and that all other necessary proceedings be taken to recover payment of the sum due."

**Southampton.**—A good deal of discussion ensued at the last meeting of the Town Council over the clause in the Tramway Committee's report embodying the report of the general manager. In the course of the report, it was stated that the relay of the track in parts of Lodge-road was proposed to be proceeded with immediately, the idea being to relay the portion of single track between Stag Gates and the first loop, and to work on down Lodge-road by sections, relaying those parts which were extremely defective and dangerous, and leaving any considerable length which would not require attention this year. New 7in. rails with welded joints were to be used. It was proposed to take in hand and repair forthwith such short lengths of the rest of the track as were in the worst condition. The general manager expressed the opinion that if the track in High-street were taken in hand as soon as possible, it might be made to last several years longer. The same remarks applied to the Avenue and the rest of the Shirley-road which had not been reconstructed. With regard to the Portswood-road track between St. Denys-road and Avenue-road, he considered it should be relaid throughout. As the energies of the staff would be fully engaged in every other part of the town effecting sectional relays, the general manager proposed, if it were decided that Portswood-road should be reconstructed, to advertise immediately for tenders for carrying out the work. It was desirable to do so at once, because two valuable months had already gone, and with regard to new rails, the mills were now somewhat slack, though they would probably be busy in about six weeks' time. He proposed to adopt a new method of getting rid of rail corrugation, and the apparatus would be made in their own workshop. The manager is unable to give a reliable estimate, as it is not yet known to what extent the reconstruction of the track has deteriorated till the setts, etc., have been stripped. The manager's report proceeds: "That this expenditure is needed I am convinced, and, further, if the deterioration had been taken in hand 12 months ago, it could have been checked with possibly half the present expenditure, while if the work is not done now it will very likely cost double next year to effect the same result. The electrical equipment of the cars and overhead work being in a high state of efficiency will help us a great deal, and if the committee will only give me a free hand, a similar state of affairs in other directions will be obtained. I have several proposals to make for dealing with rail corrugation, but it will be necessary to bring the road surface into better condition before these are tried. As you are aware, meetings of tramways engineers are being held at various places to deal with this vital question." The report was eventually adopted.

**Reading.**—The report of Mr. W. Binns, general manager of the Corporation tramways, for the past year states that the total receipts from all sources amounted to £33 573. 4s. 10d., and the total working expenses to £18 892. 9s. 8d., leaving a gross profit of £14,130. 15s. 2d. Interest and sinking fund absorb £11,757. 0s. 2d., leaving a net profit on the year's working of £2,923. 15s., which, with a balance of £618 10s. 4d. brought forward from last year, leaves £3,542. 5s. 4d. available for appropriation. Mr. Binns recommended that this be placed to a reserve or renewals fund account, to meet the heavier items of expenditure which will arise as time goes on, consequent on the depreciation of the equipment. Mr. Binns added: "As I have pointed out on previous occasions, some municipalities have unwisely put what they termed profits to the relief of the rates, without first building up a reserve fund for depreciation and renewals, and their subsequent experience has proved that the policy was financially unsound. I am hopeful that with steadily increasing traffic and increased revenue from other sources, still better results may be obtained during the coming year." The number of miles run by the cars was 872 426, and the traffic receipts per car mile amounted to 8·98d., or ·97d. per passenger carried. The total traffic receipts amounted to £32,650. 10s. 1d. Mr. Binns stated that if the Corporation had obtained the large bogie cars for use during the summer months, the receipts would have been better, but the summer was almost over when they were delivered. By slightly increasing the speed of the cars the time taken on the various journeys can be reduced, and arrangements have been made for some time past for carrying this improvement into effect, but until the public were well accustomed to the higher speeds of the electric cars, compared to the old horse cars, Mr. Binns thought it inadvisable to make any alteration, but he thinks that the service may now be accelerated without danger. In the autumn the parcel system was commenced, and is developing, a sum of about £140 having been obtained from this source during the past few months. The consumption of electric current per car mile was 1·02 units, which which is well below the average of most tramway systems; 1,020,400 units have been generated during the year, the works costs per unit being ·74d, as against ·85d. during the first 8½ months of electric traction—from July 22, 1903, to March 31, 1904. The permanent way has been carefully inspected and defects remedied as soon as they were observed, but the paving of the permanent way, where lava setts have been laid, is causing considerable expense. The permanent way in Duke-street, parts of Caversham-road, King-street, and Bridge-street has already been relaid, and other parts of the track where lava setts are laid will have to be repaved in the near future. The report was adopted.

## LIGHTING AND GENERAL.

**West Hartlepool.**—Sanction has been received to the borrowing of £2 200 for the provision of additional plant.

**Swanage.**—The National Telephone Company are just connecting the various places in the town with the local exchange.

**Southampton.**—The head telegraph office at Southampton will soon be transferred to the new premises erected near the docks.

**Wednesbury.**—The electrical main in Walsall-street is to be extended a distance of 370 yards down Spring Head at an estimated cost of £96.

**Islington.**—The Borough Council have decided to borrow £15,500 for electric lighting extensions. Details of the scheme appeared in our issue of April 28.

**Bills.**—The Andover Lighting and Power Bill and the South Wales Electrical Power Distribution Company's Bill have been read a third time in the House of Commons.

**Swansea Telephones.**—The telephone manager's last report shows that there are 1,171 lines and instruments working, 1,034 subscribers on the books, and 178 orders in hand.

**Manchester.**—The Corporation have placed an order with Ferranti Limited for the supply of continuous-current switchgear for the Dickinson-street generating station.

**Winchester.**—An attractive electrical exhibition has been held at the St. John's Rooms under the auspices of the Winchester Electric Light and Power Company, Limited.

**Stockport Telephones.**—The Stockport tradesmen have joined in the protest against the purchase of the National Telephone Company's concern on the terms of the provisional agreement.

**St. Annes.**—The output at the electricity works for the year ending March 31 totalled 589 500 units, an increase of 105,518 units. The number of consumers had increased by 72, and was now 321.

**Colne.**—An application of the National Telephone Company, asking for permission to lay underground conduits along the public highways in Colne, has been referred to the borough surveyor for report.

**Sale of Plant.**—The Aldershot Urban District Council have for sale 24 Watson penny prepayment meters calibrated for a 210-volt circuit with energy at 6d. per unit. Details in another column.

**Brighton.**—An enquiry was held on the 11th inst. into the Town Council's application for sanction to borrow £11,617 for purposes of the Council's telephonic undertaking. The undertaking shows a profit of £413 for the past year.

**County of London Electric Supply Co.**—The sales in the London district during the quarter ended March 31 are estimated to realise about £41,895, which compares with £37,925 for the corresponding period of last year.

**South Africa.**—An immediate increase in the electrical equipment of the General Electric Power Company, Limited, Brakpan, Transvaal, has been decided upon. The Vryheid (Natal) Local Board have decided to instal an electric light service, and orders for the material required will shortly be forthcoming. Two 400-b.h.p. electric motors are to be installed in each 220-stamp mill of 1,350lb. stamps at the Angelo and Cason gold mines. The *British South African Export Gazette*, to which we are indebted for the above items, also mentions forthcoming developments in Krugersdorp electric lighting, and an increased demand for electric motors in the Transvaal and Natal for mining and manufacturing purposes.

**Stock Exchange.**—The Stock Exchange Committee have ordered the undermentioned securities to be quoted in the official list: Electric Lighting and Traction Company of Australia further issue of £70,000 5 per cent. first debenture stock, and Primitiva Gas and Electric Lighting Company of Buenos Ayres further issue of £55,000 4 per cent. first debentures of £100 each, Nos. 4,451 to 5,000. Applications have been made to the committee to allow the following securities to be quoted in the official list: Baker-street and Waterloo Railway Company's £500,000 4 per cent. debenture stock, in lieu of the Speyer Bros.' scrip certificates now quoted; British Electric Traction Company's further issue of £448,653 5 per cent. perpetual debenture stock, and £158,623 4½ per cent. second debenture stock; Consolidated Electrical Company's 110,000 ordinary shares of £1 each, fully paid; County of London Electric Supply Company's £250,000 4½ per cent. second debenture stock, in lieu of the provisional certificates now quoted, together with a further issue of £150,000 4½ per cent. second debenture stock; Rosario Electric Company's 12,000 6 per cent. cumulative preference shares of £5 each, fully paid.

**Fulham.**—At a recent Council meeting a resolution was passed consenting to the erection of temporary poles in Queensmill-road to carry overhead wires for fire-alarm purposes as required by the London County Council. Since then a letter has been received from the Postmaster-General pointing out that in view of his statutory powers, he would be unable to accept a condition limiting the use of poles to any specific purpose, nor would he be justified in agreeing to the erection of temporary poles, a condition which would be equivalent to an undertaking to remove the poles at the request of the Council at any time. As an alternative to this condition he would not object to the Council reserving a power to withdraw their consent at, say, three months' notice. This would safeguard the Postmaster-General's right of appeal and preserve a principle to which he is obliged to attach great importance. The Council propose to consent to the placing of an overhead telegraphic line on the understanding that the Postmaster-General is to make good any damage which may be done in the placing or maintenance of the line, the Borough Council reserving power to withdraw such consent at three months' notice. The Electricity Committee have recommended that the alterations to the rectifier room at the electricity works be carried out by the borough surveyor by direct labour at a cost of £250.

Digitized by Google

**Barrow.**—The electrical engineer is sending circulars to all consumers of electricity informing them that the meter readers will in future wear badges, and requesting that no person without such badge be allowed to examine the metors.

**Wood Green.**—The Urban District Council complain about the above-ground telegraph lines on the south side of Lordship-lane. It is contended that they had spent money in beautifying the district, and now these ugly poles would spoil their efforts.

**Cheltenham.**—The process of wiping off the electricity deficit will take a rate of 2d. in the £ for 10 years. Last year's expenditure amounted to £15 364, and was below the estimate. For the present year it is estimated that £9,246 will be required.

**Agency.**—Mr. C. R. Heap, 47, Victoria-street, S.W., has been appointed sole agent for London and 11 adjacent counties for the direct and alternating current motors and dynamos and starting switches manufactured by Messrs. Hodgson, Wright, and Wood, of Halifax.

**Bishop's Stortford.**—The promoters of the Bishop's Stortford electric lighting order having agreed to the insertion of a clause for the protection of the interests of the county in regard to bridges and approaches, the Herts County Council's opposition to the order has been withdrawn.

**Newcastle.**—The Newcastle and District Electric Lighting Company on Tuesday decided that on and after July 1, 1905, the price of electricity for lighting should be 4½d. per Board of Trade unit, with an allowance of 1d. per unit on accounts paid monthly as at present, making the price 3½d. per unit net.

**Macclesfield.**—Mr. Woodward has undertaken to formulate a scheme of electricity for the borough. The following sub-committee has been appointed to report on suitable sites for a generating station: The Mayor, Alderman Brocklehurst, Councillors Cameron, W. R. Brown, Isherwood, Clayton, and Bailey.

**Worthing.**—It is proposed to apply for sanction to a loan of £3,000 for extension of plant, mains, etc., required to enable the electric light works to deal with the demands of next winter. These include an additional boiler with steam and water pipes at an estimated cost of £860, and extensions of feeder and of distributing mains.

**New Zealand.**—The Auckland Council are considering a proposal by Mr. P. M. Hansen, managing director of the electric tramways company, for the supply of current for public street-lighting. Mr. R. D. D. McLean is installing an electric power plant for his Maraekakaho sheep station. The Westinghouse Company have obtained the contract.

**Ayr.**—Thirteen new consumers were connected during April, making a total of 866; 344 lamps were connected (total, 37,050), and one motor (total, 32). The units generated during the month were 86,948 (total for the year, 1,250,526). The units generated for the corresponding period last year amounted to 1,179,158. There is thus an increase of 71,368 units.

**East Molesey.**—The District Council have approved plans from the Twickenham and Teddington Electric Supply Company for the laying of their cables in 20 roads in the district, subject to the work being completed within three months from the date of its commencement, and to a schedule of prices being agreed for the reinstatement of the footpaths by the Council.

**West Bromwich.**—The Town Council have approved a report with respect to the proposed purchase of the National Telephone Company's system by the Government, and recommended the adoption of a resolution expressing the opinion that such a transaction could not be effected on terms which would permit of the provision of a permanently cheap and effective service, and strongly urging adherence to the policy embodied in the Telegraphs (Telephones) Act, 1899.

**Dublin.**—The Corporation at their last meeting discussed and passed the following resolution: "That report No. 60, together with the letter from Messrs. Robert Hammond and Son, be referred back to the Lighting Committee, the committee to confer with Mr. Robert Hammond regarding the amendment of the existing agreement suggested in the letter from Messrs. Hammond and Son, and to report thereon to the next ordinary meeting of the Council."

**Nelson.**—The price of current for lighting and motive power has been reduced as from April 1 as follows: For lighting—up to 1,000 units per annum, 4d. per unit; up to 3,000 units per annum, 3¾d. per unit; up to 5,000 units per annum, 3½d. per unit; up to 8,000 units per annum, 3¼d. per unit; over 8,000 units per annum, 3d. per unit. For motive power—for the first hour, 2½d. per unit; and for every subsequent hour 1½d. per unit. All these charges are subject to 5 per cent. discount in all cases for prompt payment.

**Morley.**—The borough electrical engineer, Mr. J. E. Ellis, in his last report gives the output from the electricity works during the month ending March 31 as 13,993 units, which compared with 13,722 in the corresponding period last year shows an increase of 271 units. The quantity consumed by meter was 9,812 units, as compared with 8,703 the same period of last year, being an increase of 1,109 units. There were 296 lamps connected during the month and 26 disconnected, the total number of lamps connected to date being 12 571.

**Hastings.**—In order to locate faults in the distributing network at Warrior-square, four disconnecting boxes are to be placed in the square at an estimated cost of £80, to be defrayed out of the loan of £4,500 sanctioned for new mains. The high-tension feeder between the works and the sub-station at the hospital is to be extended at a cost of £380. In his last report, which has been adopted by the Council, Mr. Fergusson, electric light engineer, mentions that, owing to the reorganisation of the electric lighting department, Mr. Glass has been placed in charge of the public lighting department at an increased salary.

**Stockton.**—Over 34,900 lamps were connected during the quarter, and applications have been received for 60 more. The units sold numbered 178,930, against 135,560 in the corresponding quarter of last year. At the last Town Council meeting Mr. Tomkins, chairman of the Electricity Committee, said that the cost of production had been cut down in every item, with the result that the committee were able to allow the following substantial discount to consumers of electricity for business purposes: 2½ per cent. on accounts of between £100 and £200 per annum, 5 per cent. between £200 and £300, and 10 per cent. £300 and upwards.

**Arc Works Club.**—This football club (Messrs. Crompton and Co., Limited, Chelmsford) report a very successful season, with the following results: The first eleven are champions of the Chelmsford and District League, having won the cup and medals. The reserve team are champions of the second division of the Chelmsford and District League, and also receive medals. The first eleven are joint holders with Halstead in the North Essex League. The result of the matches played during the season is as under: Arc Works First, played 25, won 20, lost 3, drawn 2, goals for 118 against 39; Arc Works Second, played 17, won 12, lost 2, drawn 3, goals for 54 against 23.

**Burton-upon-Trent.**—An enquiry has been held into the application of the Town Council to borrow £16 165 for electric light extension, and to replace £6,000 excess of expenditure already incurred on behalf of the electric lighting. The electricity accounts show a total income of £9,791, against £8 962 last year, an increase of £729. The total expenditure, including the surplus, has been £9,791, against £8 962, and the surplus is only £357, as compared with £1,197, a decrease of £840, but this year £303 will be contributed to a sinking fund (reserve) contribution, and this was absent from the sheet last year. The increased income is due to the tramways, which paid £1,337 more for power than in the previous year, and motors also took about £200 more than last year. Against these increases, however, there was a fall of £585 in the sale of current for lighting.

**Worcester.**—Alderman Millington's suggestion regarding the sale of the electricity works was mentioned at the last Council meeting. It was said that such an event would set at liberty a very considerable sum of money—something like £100 000—and that would cover the outlay upon the sewerage works, which would mean a considerable saving in the rates. Others thought that as there was a new engineer it would not be fair to entertain such a proposal until they saw whether he could make the concern pay. It was stated that no doubt the Electricity Committee would take Alderman Millington's suggestion into consideration, but it was hoped that they would not adopt it. It is now 10 years since the works were opened, and the total expenditure to Dec. 31 last amounted to £123 950, but repayments had been set on one side, amounting to £20,850, so that at that date the net capital was £103,100. There has been an annual loss of £428 since the works opened.

**Canterbury.**—The receipts of the electric light undertaking for the year amounted to £6,925, the works costs and loan repayment and interest to £6,720, leaving a balance of £205, representing the net profits of the year's work. The balance brought forward from last year was £911, but the costs of the renewal of the accumulators amounted to £570, which reduced the balance to £341, and left £546 to be carried forward. Although there was an increase of 11½ per cent. on the total amount of current sold to private consumers during the year, the work has been done at 7 per cent. less cost in coal than the previous year. The increase in private lighting consumers was equal to 1,885 8 c.p. lamps, or an increase of 10 per cent. The reduction in price of current of 1d. per unit made a difference of £776 in the year's revenue. Had the price not been reduced the net profit would have been £981. During the year a new battery of accumulators was bought at a cost of £570, and partly paid for out of the previous year's profits.

**Hammersmith.**—At the last meeting of the Board of Guardians a letter was read from the Local Government Board, stating that with regard to the electric lighting, etc., of the new workhouse and infirmary, the questions involved, such as the propriety of accepting a lower tender than that provisionally accepted and the necessity or otherwise for incurring the proposed large expenditure on the transforming scheme, were matters which the Guardians should investigate with the view of ascertaining whether the scheme could not be carried out at a less cost than that proposed; also further stating it did not appear to the Board any advantage would result from their receiving the proposed deputation from the Guardians. The Chairman said that the Guardians having now received the schedule in connection with the electric lighting they had resolved to give an opportunity to the whole of the firms who had sent in tenders on the previous occasion, and that they would consider the same on the 17th inst. This mistake, therefore, had been rectified. The proposition was agreed to.

**Portsmouth.**—An enquiry has been held into the application of the Corporation for sanction to borrow £21,835 for the purpose of extending the municipal telephone system and £8,000 for extensions at the electric light works. Mr. W. S. Foale, the superintending engineer at the electric lighting works, said the net profit on the year's working for 1903 had been £3,000, and £4,000 in the following year, while the reserve fund amounted to £11,725. Mr. Hammond Etherton, the deputy town clerk, said it was intended to bring the present number of telephone lines up to 3,000. The principal items were £5,194 for a new underground route to Stamshaw and North End, which was to be a cable of 312 pairs, and of three new sections of the multiple switchboard at the central exchange room for 960 new lines—640 at once and 320 as the necessity arose—for which £2,134 was required. The other amounts were for work at Gosport, a switch-room at Porchester, etc. The system had been working since March 1, 1903, and the first year's profit was £1,233. 18s. 10d., while last year the amount of profit on the year's working was £1,969. 9s. 8d., of which £614 had been paid over to the suspense account.

**Durham.**—Amongst the various matters which were brought before the County Council, but had to be postponed owing to the lateness of the hour when they were reached, was a report of the Electricity Supply Committee, which contained the following resolution: "That the Durham County Council hereby resolve to promote a Bill in Parliament having for its object the establishment of a system of electrical services for the county of Durham." There was also a paragraph relating to the Houghton-le-Spring and District electric lighting provisional order, as follows: "The Board of Trade, dated 6th inst., have granted the Houghton-le-Spring and District electric lighting order and have not been able to insert the clause submitted for the protection of the Durham County Council. We think the practice of a paid Government official having power to supersede and ignore the collective opinion of a large representative body like the Durham County Council upon questions immediately touching the welfare and working of the county is fraught with the greatest danger to public interest. It appears reasonable to assume that whilst a county council are actually engaged in developing a county scheme of electric service for the convenience and welfare of all, that it is the obvious duty of the Board of Trade not to hamper and well nigh render impossible the evolution of such a scheme by handing over to private companies a monopoly over large portions of the county for nearly half a century to come. It amounts to the removal of the administration in a very important sense from our representative assembly in Durham to a Government office in London, and should not be allowed to pass without protest."

## PROVISIONAL PATENTS, 1905.

MAY 1.

**9101. Improvements relating to electrical connections.** Philip Henry Jones, 25, Allesley Old-road, Coventry. (Complete specification.)

**9107. New or improved method of constructing or manufacturing electric traction cells, accumulators, and electric storage or secondary batteries.** Georges Schauli, 173, Fleet-street, London.

**9110. Improvements in the distribution of electricity.** Andrew Sweet, Butleigh, Friern-lane, Whetstone, London.

**9113. Improvements in dynamo-electric machinery by means of which a constant voltage may be produced at varying speeds.** John Herbert St. Hill Mawdsley, Norfolk House, Norfolk-street, Strand, London.

**9120. An electric periodical switch.** Armand Frey, 41, Rominterstr., Berlin, Germany. (Date applied for under Patents Act, 1901, Aug. 3, 1904, being date of application in Germany.) (Complete specification.)

**9134. Improvements in and connected with the charging and discharging of secondary batteries applicable to electric train-lighting installations.** J. Stone and Co., Limited, and John Robert Quain, 77, Chancery-lane, London.

MAY 2.

**13736a/04. Improvements in apparatus suitable for detecting electrical oscillations.** John Ambrose Fleming, 24, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents Rule 9, June 17, 1904.)

**9161. Watertight electric lamp for motorcars.** Charles Edward Clark, 395, Summer-lane, Birmingham.

**9162. Improvements in trolley collectors or the like.** Samuel Feather, George Robert Feather, Herbert Henry Feather, Edward Earnshaw Feather, and John William Astley, Moses Gate Brassworks, near Bolton.

**9181. An improved electric light candle fitting.** Hugo Hirst and John Hillery Collings, 71, Queen Victoria-street, London.

**9203. Improved method of electrically operating hydraulic apparatus for opening and closing bulkhead doors of ships and the like.** Edmond Meyer Tudor Boddam, 23, Savernake-road, London.

**9216. Apparatus for purification of water by electrical means.** James Slough Zerbe, 81, High Holborn, London. (Date applied for under Patents Act, 1901, May 2, 1904, being date of application in United States.) (Complete specification.)

**9219. Improvements in coherers.** Guiseppe Magini, 52, Chancery-lane, London. (Date applied for under Patents Act, 1901, May 8 1904 being date of application in Italy.) (Complete specification.)

**9257. Improvements in and means for the electrical regulation of the speed of internal-combustion engines.** Marquis Albert de Dion and Georges Bouton, 47, Lincoln's-inn-fields, London. (Date applied for under Patents Act, 1901, Dec. 23, 1904, being date of application in France.) (Complete specification.)

MAY 3.

**9274. An improved device for preventing accidents through the breakage or dislocation of overhead electric wires.** George Porritt, 6, Finkle-street, Stockton-on-Tees.

**9279. Improvements in apparatus for controlling the supply of energy from alternating-current generators to alternating-current motors.** Arthur Pemberton Wood, 34, Castle-street, Liverpool.

**9296. Improved trolley wheel for use in electric traction.** Firth Bamforth, 51, Deansgate-arcade, Manchester.

**9303. An improved electric switch or protective circuit breaker.** Louis Rutledge Gleason, 420, Uxbridge-road, Shepherd's Bush, London.

**9344. New or improved electric current meter.** Jacob Kruyswijk, 77, Chancery-lane, London. (Date applied for under Patents Act, 1901, May 5, 1904, being date of application in Germany.) (Complete specification.)

**9346. Improved construction of electric accumulator for small arms.** Alexander Elias Dakhyl and Antonio Galanti, 173, Fleet-street, London.

**9347. Improvements in sytems of control for magnetic clutch speed-changing gears, applicable more especially to self-propelled vehicles.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

MAY 4.

**9363. An electromagnetic release for photographic shutters.** Francis Noel Gasquoine, St. Oswalds, Upper Bangor, North Wales.

**9401. Improvements in electric contact devices.** James John Walker, 17, London-road, Wembley, Middlesex.

**9405. Improvements in electromagnetic switch-operating mechanism.** Frederick Theodore Kitt, 52, Chancery-lane, London. (Complete specification.)

**9430. Improvements in electrical switches or circuit breakers.** The British Thomson-Houston Company, Limited, and Edwin Joseph Murphy, 83, Cannon-street, London.

**9431. Improvements in vapour electric apparatus.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

**9439. Improvements in fireproof casings and covers for electric conductors.** Henry Redmayne Romney, 65, Chancery-lane, London. (Complete specification.)

**9447. Improvements in the electrolytic refining of copper.** The Metals Corporation, Limited, and Sherard Cowper-Coles, 70, Chancery-lane, London.

**9448. Improvements in and relating to the electrolytic deposition of metals.** Sherard Osborn Cowper-Coles, 70, Chancery-lane, London.

**9455. Combined kerbstone and electric wire conduit.** Patrick John Donohue, 40, Chancery-lane, London. (Complete specification.)

MAY 5.

**9467. An improved method for equalising electrical power when the power required is of an intermittent or variable character.** Rudolf Braun, 4, St. Ann's-square, Manchester. (Complete specification.)

**9475. Improved door for electric switchboard.** John McAllister, 3, St. Joseph's-terrace, Marlborough-park North, Belfast.

**9479. Improvements relating to the electric lighting of railway carriages and other vehicles.** The Electric and Ordnance Accessories Company, Limited, and Robert Frederick Hall, 24, Temple-row, Birmingham.

**9481 Improvements in or relating to electrically illuminated signs or advertising devices.** Percy Beresford Wright Kershaw, 57, Chancery-lane, London.

**9489. Improvements in or connected with dynamo-electric generators and motors.** William Wright Howe, 71, Albion-street, Leeds.

**9501. Improvements in or relating to incandescent electric lamps.** Norman Scholefield Tennant, 50, Wellington-street, Leeds.

**9508. Improvements in skates or collectors for electrically-driven vehicles operated by any surface-contact stud system.** Robert Brown, 16, Great George-street, Westminster.

**9522. Improvements in electric resistance furnaces.** James Francis Bottomley and Arthur Paget, 55, Chancery-lane, London.

**9542. Means for automatically operating the points of slot-conduit electric tramways.** William Arthur Lawrance, 4, South-street, Finsbury, London.

**9543. Improvements in or connected with primary batteries.** Richard Joseph Crowley and Arthur William Macleod, 4, South-street, Finsbury, London.

MAY 6.

**9565. Apparatus for making and breaking electric circuits.** Frank Smith, 51, Deansgate-arcade, Manchester.

**9577. A portable hand electric battery.** Benjamin Seacombe, 170, Knutsford-road, Warrington, Lancs.

**9584. Improvements in or relating to terminals or connectors for electrical conductors.** Athelstane Corderoy and John Frederick Pannell, 111, Hatton-garden, London.

**9602. Improvements in electricity meters.** Stanley Matthews, 4, South-street, Finsbury, London.

**9607. Improved method of and means or apparatus for controlling electric switches and like apparatus in electric current distributing systems.** Guy Carey Fricker, 46, Lincoln's-inn-fields, London.

## COMPLETE SPECIFICATIONS ACCEPTED.

*To be published May 25.*

1904.

**9518. Hangers or ears for overhead electric trolley wires.** Richardson, Heap, Heap, Bailey, Brierley, and Billington.

Digitized by Google

**9969. Electrically-driven coal whips or hoists.** Wilhelmi.

**10070. Regulating sockets or switches for electric lighting, heating, or power purposes.** Bogia.

**10080. System and apparatus used therein for the distribution of electrical energy over a large subdivided area.** Tanner.

**10081. Electric meters.** Venner.

**10461. Multiple electric switch rheostats.** British Thomson-Houston Company, Limited. (General Electric Company.)

**11368. Electric switches suitable for use in connection with telephonic apparatus and for other purposes.** Graham.

**11930. Alternating-current electric motors.** British Thomson-Houston Company, Limited. (General Electric Company.)

**12192. Brush-holders for dynamo-electric machines.** British Thomson-Houston Company, Limited. (General Electric Company.)

**12340. Electric cut-outs, switches, and the like.** British Thomson-Houston Company, Limited, and Cubitt.

**12373. Electrical maximum demand indicator.** Nalder Bros and Thompson, Limited. (White.)

**12970. Small dynamos and motors.** Wright.

**13624. Brush gear specially applicable to commutators of the internal ring type for dynamos and electric motors.** Maclean.

**13862. Electric arc lamps.** British Thomson-Houston Company, Limited. (Allgemeine Elektricitäts-Ges.)

**14071. Apparatus for raising, supporting, and lowering of electric arc lamps.** Berry and Skinner.

**14733. Electric arc lamps.** Carolan. (General Electric Company.)

**14734. Electric arc lamps.** Carolan. (General Electric Company.)

**14735. Electric arc lamps.** Carolan. (General Electric Company.)

**14740. Electric meters.** British Thomson-Houston Company, Limited. (General Electric Company.)

**14770. Electric light reflectors.** Hirst and Collings.

**15034. Electric arc lamps.** Crompton and Co., Limited, and Hodgson.

**21131. Automatic electric switching devices applicable to flash advertising signs and the like.** Percy Benson Harrison Seabrook, Henry Herbert Parkes Seabrook, and Leonard Kingsill Job.

**21846. Electric switches.** Cameron.

**22000. Electric motors.** Jigouzo. (Date applied for under International Convention, Oct. 21, 1903.)

**23399. Electric switches or cut-outs for disconnecting conductors in case of breakage.** Ellor and Ellor.

**23716. Devices for preventing sparking at the commutators and like contact devices of electric motors.** Allgemeine Elektricitäts-Ges. (Date applied for under International Convention, Nov. 2, 1903.)

**23991. Magnetic suspensions for the moving parts of measuring instruments.** Allgemeine Elektricitäts-Ges. (Date applied for under International Convention, Nov. 6, 1903.)

**25643. Space telegraphy.** Stone. (Date applied for under International Convention, Nov. 25, 1903.)

**25846. Space telegraphy.** Stone. (Date applied for under International Convention, Nov. 25, 1903.)

**27199. Method of accelerating the excitation of dynamo-electric machines.** Siemens Bros. and Co., Limited. (Siemens-Schuckertwerke G. m. b. H.)

**28393. Electric current governors or electromagnetic switches.** Boult. (Richards.)

**29014. Electric switches.** Longden.

**29401. Pendant electric fixtures.** Lake. (Bradshaw, Keough, Keough, and Keough.)

**29532. Electrical signalling apparatus.** Holmes. (Date applied for under International Convention, March 19, 1904.)

1905.

**493. Electromagnets for use in electric meters.** Blathy.

**1681. Insulators for electric conductors.** Marconi's Wireless Telegraph Company, Limited, and Turnbull.

**3371. Mechanism for actuating electrical clocks.** Schönberg.

**4062. Sparking plugs operating with magneto-electricity for gas or oil engines.** Rene.

## NOTES.

**Royal Institution.**—On Thursday, May 25, at five o'clock, Prof. J. A. Fleming will deliver the first of three lectures on "Electromagnetic Waves." These are the Tyndall lectures. The Friday evening discourse for May 26 will be delivered by Prof. J. W. Brühl on "The Development of Spectro-Chemistry," and on June 9 Sir William White will lecture on "Submarine Navigation."

**New Electric Lighting Regulations.**—After considering the various observations on the drafts of the revised regulations, the Board of Trade have decided to issue four sets of regulations to meet the following cases of electric lighting undertakings owned by (1) local authorities in the provinces; (2) a company in the provinces or in the city of London; (3) a company in any part of London except the City; and (4) a local authority in London.

**Royal Society.**—The following, among others, were last week elected as Fellows: Prof. William Arthur Bone, lecturer on chemistry, Manchester; Prof. William Henry Dines, meteorologist, London; Prof. Martin Onslow Forster, assistant professor of chemistry, Royal College of Science, London; Frederick Gowland Hopkins, reader in chemical physiology, Cambridge; George William Lamplugh, district geologist on the Geological Survey, Ireland; and George F. C. Searle, senior demonstrator in Cavendish Laboratory, Cambridge.

**Engineering Standards Committee.**—We have received a copy of Report No. 13 (published by Messrs. Crosby Lockwood and Son, at 2s. 6d.), which deals with the standard specification for structural steel for shipbuilding. The committees which dealt with No. 13 were composed of representatives of the Admiralty, Board of Trade, Lloyd's Register, Iron and Steel Institute, North-East Coast Institution of Engineers and Shipbuilders, British Corporation for the Survey and Registry of Shipping, Bureau Veritas, Steel Ingot Makers' Association, and other bodies. The report deals with the process of manufacture, testing and inspection, branding, makers' certificate, rejected material, etc.

**Manchester Section.**—The report of the committee for the fifth session records that the attendance at the meetings has been well maintained, the average number present being about 180. Nine papers were presented, and a large proportion of the members participated in the discussions. The fourth annual dinner was a most successful function, over 200 members and visitors being present. The membership of all grades aggregates 764, a substantial advance on the 549 of last year. Great success has attended the formation of the Students' Section, the membership of which numbers 306. Eight meetings were held, and a similar number of visits paid by the juniors. The chairman of the section for 1905-6 is Mr. S. L. Pearce, and the vice-chairman Mr. T. L. Miller. In conclusion, the committee express the hope that the members will assist them in every way possible to still further increase the usefulness of the section.

**Electric Lighting in Auckland (N.Z.).**—The Corporation is again considering the substitution of electricity for gas in connection with street-lighting, this course being recommended by their engineer. The electric tramways company has made definite proposals for the supply of current, and the Corporation have referred the matter to committee. The inhabitants appear to be decidedly in favour of the new illuminant. Great improvements have been and are being effected throughout the colony by the erection of electric tramways and the installation of electric light, but in the present instance a question of finance appears to be the obstacle. We do not gather that the Auckland coffers are in a particularly bad way, and the Corporation have presumably been guided by motives of prudence in refraining hitherto from exercising the powers obtained in 1891 and again in 1900. This policy is certainly preferable to improvident expenditure, but it is to be hoped that the Auckland councillors will not be ultra-cautious in their methods.

**The Telephone Transfer.**—In the House of Commons on Tuesday Sir H. Campbell-Bannerman, in asking what the order of business would be, said that the first order of the day—the appointment of the committee on the telephone agreement—had only been announced the previous night, and considerable objection had been taken to it. He hoped, therefore, it might be postponed. In reply, Mr. Balfour stated that he should be happy to meet the wishes of the right hon. gentleman as far as possible, although time was rather of the essence of the matter. There was a general wish on both sides that the committee should report, and that before the end of the session the Government should be in a position to find a day for the discussion of the report. He should be prepared to postpone the motion for the appointment of the committee until Monday next, and he hoped that the debate would not assume undue proportions, but that the House would assist the Government to carry through the appointment of the committee, which had been nominated in deference to the general wish of the House.

**Underground Telegraphs.**—The Associated Chambers of Commerce of the United Kingdom recently forwarded to the Postmaster-General a memorial urging the importance in the interests of trade and commerce of all trunk telegraphic wires being laid underground, so as to obviate the delays caused by storms breaking down the overhead wires. The Postmaster-General has replied that last year £150,000 was spent on the underground line to the North, and with the assent of the Treasury he has included the same amount in the estimates for the current financial year. With that amount he will be able to complete the underground line from London to Glasgow and to begin underground lines to the east and to the west from London. In conclusion, he expresses his appreciation of the importance of underground trunk telegraphs, giving this information as evidence of the importance attached by him to the provision of underground trunk telegraphs, and he is of opinion that Parliament could not be asked to sanction a larger expenditure, and that his department could not economically proceed with greater rapidity.

**Electric Tramway and Railway Exhibition.**—The third International Electric Tramway and Railway Exhibition will be held at the Royal Agricultural Hall, London, from Monday, July 3, to Friday, July 14. The exhibitors who have already secured space exceed 150. The exhibits will comprise many interesting designs not shown at the earlier exhibitions, and will include several systems of surface-contact tramways, new types of tramway cars, motor omnibuses, and a great variety of small appliances for car equipment, overhead work, and track construction. It is expected that demonstrations of several new processes and apparatus will be carried out at the exhibition. More than 80 town councils will appoint official deputations to visit the exhibition, and it is expected that every important tramway will be represented. The Municipal Tramway Association and other tramway and scientific bodies will hold conferences at the exhibition, which is likely to form a centre of the greatest interest to all concerned in such matters. A few good stands are still available, and intending exhibitors should make early application to the *Tramway and Railway World*, Amberley House, Norfolk-street, Strand.

**Electrolytic Method for Separating Ores.**—At the recent meeting of the American Electro-Chemical Society, Prof. L. I. Blake presented a paper upon the Blake-Morscher electrostatic separator, of which an abstract appears in the *Electrical World* of New York. The author prefaced his description with the statement that where there is a mechanical mixture of two kinds of crushed materials with different electric conductivities, and this mixture is brought into contact with an electrostatically charged surface, the two different materials will get a different charge in the same time. If, for instance, one material is a conductor, and the other a non-conductor, the latter will remain uncharged, while the former gets a charge. As soon as this takes place the charged particles only are repelled from the charged surface, so that in this way a separation of the conducting and non-conducting materials is accomplished. This is the fundamental idea on which the electrostatic separator is based. To carry out the process in practice it is necessary first to crush the ore; secondly, to dry it thoroughly; thirdly, to feed it in a suitable manner to the charged surface; and, fourthly, to collect and remove the separated materials. The voltage required is 350,000, and is furnished by a special electrostatic machine, acting, not by friction, but by induction. The leakage in the electrostatic separator is considerable, but notwithstanding this, the total power required for a separator treating 12 tons in 24 hours is not more than 1 h.p.

**Testing Incandescent Lamps.**—At the annual convention of the Iowa Electrical Association, Prof. L. B. Spinney, of Iowa State College, read a paper, abstracted in the *Electrical World* of New York, on the lamp-testing work of that institution, which has for a number of years made a practice of testing at cost incandescent lamps sent to it by central stations of the State. Tests of mean horizontal candle-power and watt consumption are made at the rate of 4s. per dozen. Recently the department of electrical engineering has added to its equipment a Matthews integrating photometer, which will enable it to make tests of mean spherical candle-power quickly and cheaply. The author explained the principle of the Matthews photometer, which records simultaneously the candle-power from 11 different angles, and integrates the results so that a reading is obtained directly of the mean spherical candle-power. Incidentally, he called attention to how illogical is the present method of rating lamps by horizontal candle-power. This rating had been adopted mainly because of the difficulties involved in the past in making a test for mean spherical candle-power, but the only true measure of the efficiency of a lamp was the watts per mean spherical candle-power, and the proposer considered it probable that in the near future this, rather than horizontal candle-power, will be the basis of rating of all illuminants. Tests are to be made at the college to show the difference between ratio of horizontal candle-power and spherical candle-power with different kinds of filaments.

**Telephonic Intercommunication.**—An interesting judgment was delivered last week by Mr. Justice Buckley upon the question of intercommunication between the National Telephone Company's system and that of any competitor licensed by the Postmaster-General. The cause of action arose under Section 3, Sub-section 5, of the Telegraph Act of 1899, which provides, *inter alia*, that when the license of an existing system shall be extended in respect of any exchange area for a period of eight years, the proprietor shall, at the request of the new licensee, afford all proper facilities for the transmission of telephone messages over both systems, provided that the licensee requiring intercommunication shall afford similar facilities. In September, 1902, the Postmaster-General granted a license to the Swansea Corporation, at the same time extending the company's license. In January, 1904, the Corporation, having satisfied the Postmaster-General that they had obtained the requisite number of subscribers, requested the company to afford intercommunication. The company, however, raised objections. They had a central exchange at Swansea and some dozen subsidiary exchanges, and they required that the Corporation should provide junction circuits to connect directly the plaintiff's exchange at Swansea and the company's exchange there, and with nine subsidiary exchanges and also junction circuits to connect the Mumbles and Morriston exchanges. The Corporation argued that this was contrary to the spirit of the Act, and his lordship upheld their contention, deciding that the Corporation were entitled to be afforded all facilities for restricted intercommunication as provided by the Act. We are glad to see that the statute has been interpreted upon comprehensive lines, as it is not difficult to imagine the obstruction to progress that might arise from the company carrying their stipulations to an extreme.

**The Rating of Machinery.**—The Machinery Users Association direct attention to the important question of the rating of machinery and its effect upon electrical undertakings. At a recent conference of the London County Council and delegates from the various metropolitan boroughs the following resolutions were formulated: (*a*) "That in the case of premises where the assessable value is enhanced by the presence of plant and machinery essentially necessary to the business carried on, and which it is intended should remain attached to the premises so long as they are used for the purposes of the business, such enhanced value unless already covered by the rent paid by the occupier shall be taken into account." (*b*) "That having due regard to necessary modifications in special cases, 10 per cent. of the capital value of rateable machinery shall be taken as the average percentage for gross value." (*c*) "That the maximum deduction of one-third should not be allowed as a matter of course, but the amount should vary between one-third and one-sixth, according to the proportion of machinery included in the assessment." If effect be given to these by the rating authorities of London, the rateable value of electrical undertakings will be appreciably increased, because machinery that is now considered as belonging to the occupier, and for which a certain proportion of the receipts is at present deducted as representing interest and trade profit on the capital he has invested, will no longer be allowed. While the question is comparatively new to users of machinery in London, it has agitated the minds of provincial manufacturers for many years, and at the present time the association, which was formed for the purpose of resisting the imposition of a tax upon machinery, is contesting it before a divisional court on behalf of the manufacturers of Leeds, and the result is naturally awaited with great interest. We observe that the association is being backed by a strong committee, and all sections of the manufacturing and industrial community who are threatened with additional taxation would do well to rally to its banner.

**Lighting in New York.**—The investigation into the lighting conditions of New York has come to a curious pass, the Legislature having declined to receive the committee's report. This report made the following recommendations: that (1) the price of current for heat, light, and power purposes in the boroughs of Manhattan and Brooklyn, and in part of the borough of Bronx, should be fixed at a maximum of 5d. per kilowatt-hour of current actually consumed, and that provision should be made for inspection to secure accurate metering; (2) the price of arc

Digitized by Google

lamps for street-lighting in the city of New York should be fixed at £20 per lamp per year for single lamps of 2,000 c.p., consuming 450 watts at the arc, and that the price of twin arc lamps, consuming 250 watts each at the arc, should be fixed at £13 each per year; and (3) the city of New York be given authority to utilise water power, now owned or hereafter acquired by it, for the purpose of generating electric current for the use of the municipality, provided that no additional water shall be used for said purpose that would otherwise by required by the city. It is also recommended that provision should be made for the creation of a commission, the members of which should be appointed by the Governor with the consent of the Senate, to be paid by the State, and to have general supervision of all persons and corporations having authority to lay or erect and maintain wires and pipes for the purpose of furnishing gas or electricity for light, heat, or power, with power to investigate and ascertain the character of the service and reasonableness of charges and the methods employed in manufacture and distribution and in the maintenance of works and distributing systems and to enforce the provisions of law applicable thereto; to prescribe methods of keeping accounts; to examine the corporations under its supervision; to require annual reports; and other powers. There are four Bills proposed to carry into effect the lighting recommendations. The first fixes the price of gas, the second provides for inspection of meters, the third the rates for electricity, and the fourth creates a State lighting commission.

**General Electric Company.**—The thirteenth annual report of this American company, for the year ending Jan. 31, 1905, shows a profit of some £1,350,000 after deducting all expenses and making allowances for depreciation, losses, and patent account. This, however, is subject to a further deduction of £150,000 on revaluing the assets of the Stanley Electric Manufacturing Company and other acquired interests. During the year a sum of about £750,000 was paid in dividends, the net surplus for the year being £455,000. Added to a surplus from the previous year of £1,460,000, there was a total surplus at Jan. 31 last of some £1,915,000. The company's sales for the year totalled £8,000,000, representing a diminution of 6 per cent. as compared with the previous year. Among the important orders secured by the company are contracts with the New York Central Railroad Company for 30 90-ton electric locomotives, 40,000 kw. capacity of steam-turbines, and the entire switchboard plants for the Mount Morris and Yonkers power stations; contracts with the Public Service Corporation of New Jersey, for steam-turbines and rotary converters; contracts with the Interborough Rapid Transit Company of New York, for additional control equipments and motors for operation of the subway trains; contracts for car equipments with the New York City Railway Company, the Philadelphia Rapid Transit Company, the Chicago Union Traction Company, and other traction and street railway companies; contracts for generators to develop water power in 10 States, Mexico, and other countries; contracts for 154 steam-turbines. On Feb. 1, 1905, the company had sold a total of 289 Curtis turbines capable of generating in daily operation from 450,000 kw. to 500,000 kw. The company has sold a large number of these turbines to various customers in Canada, Europe, South America. Japan, New Zealand, Mexico, and other parts of the world, The total number of cars equipped with the Sprague-General Electric control system on Jan. 31, 1905, was 2,997 cars, as against 2,595 cars the year previous. About £400,000, exclusive of the cost of patterns, special tools, etc., was expended upon sites, erection of new buildings, extensions to existing buildings, and additional machinery.

**The Tesla Patents.**—The series of American patents generally known as the fundamental Tesla patents, which have played such a conspicuous part in the electrical industry during the two last decades, expired on the 4th of this month. Mr. B. A. Behrend takes the opportunity of paying a tribute to Tesla's work in an article contributed to the *Electrical World* of New York. The genius of Tesla has been instrumental in stimulating, if not in creating, a wonderful industry—wonderful in magnitude, and wonderful in the ingenuity of the apparatus used in the accomplishing of the transmission of power over long distances. After discussing the evolution of scientific principles and the patent system, the author deals with the personal achievements of Tesla, the ingenious inventor who, by a "sort of glorified common sense and unfailing intuition, picked his way through puzzling mazes of complicated phenomena, and protected himself from the pitfalls and the alluring by-paths ensnaring smaller intellects." With Tesla, in America and in Europe, worked a host of capable and ingenious engineers, and their work, vivified by the ingenuity of Tesla's inventions, has become one of the greatest monuments of engineering achievement crowning the work of the nineteenth century. Turning to Tesla's remarkable paper, entitled "A New System of Alternate-Current Motors and Transformers," read at the meeting of the American Institute of Electrical Engineers in New York on May 16, 1888, the author remarks that this paper, even when considered in the light of previous discoveries and knowledge, is one of the most brilliant pieces of engineering thought, teeming with suggestions and ideas, animated with an intuition of the highest order, and giving an exposition of the working of the induction motor in a manner which resembles the methods pursued in the "Experimental Researches on Electricity" of the great master, Michael Faraday. While stating, however, that for 17 years the Tesla patents have formed the nucleus of the electrical industry, Mr. Behrend points out that these patents do not represent the only valuable ideas on the subject of polyphase alternating-current systems. He predicts that the expiry of the patents, aided by vigorous competition, will give the electrical industry a new stimulus.

**Pneumatic Dispatch.**—A Select Committee of the House of Commons commenced on Tuesday the consideration of the Metropolitan Pneumatic Dispatch Bill. Sir Henry Aubrey Fletcher presided. The Bill is opposed by the London County Council, a number of borough councils, and electric supply and railway companies. Mr. Balfour Browne, K.C., in explaining the Bill to the committee, said the promoters proposed to establish a system of pneumatic transport within the administrative county of London for the dispatch of parcels, goods, and messages. The scheme was to lay down 95 miles of double 12in. tubes, with 172 stations. The system proposed to be used is that known as the Batcheller. Electric power is conveyed to motors at the several stations, where the current operates air compressors. The scheme has the personal and financial support of Messrs. Barclay and Bevan (of Barclay, Bevan, and Co., bankers), Smith's Union Bank, Mr. Parr (of Parr's Bank), Mr. Hoare (of the Bank of England), Mr. J. Pierpont Morgan, and a great number of others. The capital of the company would be four millions sterling. There would be one charge for collection, transmission, and delivery of parcels in the tube area, which practically covered the whole administrative county of London. For the transmission of the parcels they would require 30,000,000 Board of Trade units of electricity per annum. The rate of transmission would be very rapid. On the

Digitized by Google

average 30 miles an hour would be the rate at which the carriers would pass from one place to another, but, if necessary, that rate could be accelerated up to 50 miles an hour. From the stations the parcels would be delivered by tricycles and vans, but the distance in London would never exceed three-quarters of a mile. The "tubes" would cost £1,057,350, the cables for carrying the current £105,000, the plant and stations £805,508, and the carriers (12,000 in number) £48,000. They hoped to carry 80 million parcels per annum. Within the administrative county the average charge would be 3·1d. per parcel, and for parcels going outside London 4·132d. There will now be an opportunity for the merits of the project to be fully discussed. If the system can accomplish anything like what is claimed for it—and it appears to have done so abroad—there is little doubt but that it would prove of great utility.

**Iron and Steel Institute.**—In the course of his presidential address last week, Mr. R. H. Hadfield gave a comprehensive review of the history of this institute, and also of the industrial outlook. One of the branches he touched upon was electrometallurgy, which, as he remarked, makers of iron and steel cannot ignore. After alluding to the work of the commission appointed by the Canadian Government, and that of M. Héroult on behalf of the French Electrometallurgical Company of Froges and La Praz, he dealt with "electric steel," in connection with which he did not think there was special virtue in the electrometallurgical process. It was necessary to look to the quality of the product in order to see whether this steel could show superiority over ordinary kinds. Whether the cost of production was lower than that of older systems remained to be proved; the energy must be generated at low cost, or it certainly would not compete with existing methods. When electric energy could be produced more cheaply—and the time, he thought, might not be far distant—there would perhaps be a different state of affairs; and the process of electric smelting might become a commercial utility. It had been worked out theoretically that with no loss of heat energy, about 131 electric horse-power days (24 hours) were required to produce a net (2,000lb.) ton of iron from 65 per cent. pure ore, but in actual practice it had been found in Sweden that 362 electric horse-power days were required for the purpose. Mr. A. J. Rossi had in the Adirondacks produced iron from titanium iron ore at a rate of £3 per ton, but this ore was reckoned at 3s. 1d. per ton, which Mr. Hadfield considered scarcely reasonable. Further, this estimate was based upon the cost of £2 per year for 1 h.p. of electric current delivered, night and day, week in and week out, which was probably much too low. Besides this, there were other considerations. A complete blast furnace producing 350 tons of pig iron per day would cost about £20,000. It had been stated that an electric furnace plant to produce a similar quantity would require a water-power-electric plant with a capacity of a least 60,000 h.p. There were few places where this could be obtained; in addition, the cost of the plant would be excessive. Pig iron had been produced by the blast furnace at as low as £1. 12s. 6d. per ton. While, however, its utility is at present limited—indeed, it has scarcely emerged from the embryo stage—Mr. Hadfield predicted that the next decade would witness great practical advances in electrometallurgy. It may be mentioned that the membership of the institute stood on Dec. 31 at 1,910, an advance of 213 as compared with the preceding 12 months.

**Lightning Research Committee.**—The committee issued its report last week, and the document shows indications of careful compilation. In a preface Sir Oliver Lodge emphasises the importance of taking into account the effect of self-induction, which until the report, many years ago now, of the Lightning Rod Conference had been quite ignored. Through the medium of the Royal Institute of British Architects, the Surveyors' Institution, and the Royal Meteorological Society 5,000 copies of a memorandum containing a series of questions were distributed among observers. The Institution of Electrical Engineers, the War Office, the Home Office, Trinity House, the United States Department of Agriculture, and Mr. John Gavey (engineer-in-chief to the Post Office), also co-operated by supplying information. The report deals with the distinction drawn by Sir Oliver Lodge between the two types of lightning discharge, designated the A and the B flash respectively. The A flash is of the simple type which arises when an electrically-charged cloud approaches the surface of the earth without an intermediate cloud intervening, and under these conditions the ordinary type of lightning conductor acts in two ways—first, by silent discharge, and, secondly, by absorbing the energy of a disruptive charge. In the B type, where another cloud intervenes between the cloud carrying the primary charge and the earth, the two clouds practically form a condenser; and when a discharge from the first into the second takes place the free charge on the earth side of the lower cloud is suddenly relieved, and the disruptive charge from the latter to the earth takes such an erratic course that no series of lightning conductors of the hitherto recognised type suffice to protect the building. The report proceeds to remark that probably the majority of the buildings in this country are not efficiently protected against the effects of a B flash, although in many cases the conductors may be said to have at least partially fulfilled their purpose by carrying off the more violent portion of the discharge. Some of the observations throw an interesting light upon the effects due to the oscillating character of lightning discharges. For instance, a discharge takes place over a lightning rod which may be in contact with or approach closely to the metallic portions of a roof. Powerful electrical oscillations are set up in the latter conductors, and dangerously high electrical pressure may be generated on the distant ends of these conductors. The report states that absolute protection of the whole of a building could only be assured by enclosing the structure in a system of wirework—*i.e.*, a contrivance in the nature of a birdcage This should be well connected at various points to earth, as nearly all buildings have gas and water pipes and other metallic conductors which are likewise earthed. Various other points of interest are referred to, and the report is supplemented by a series of observations on the rules laid down in 1882 by the Lightning Rod Conference and a summary of the latest practice abroad. Mr. Killingworth Hedges, M.I.C.E., who acts as honorary secretary to the committee, has collected a large number of expert reports on recent cases of damage done to buildings from lightning.

**Properties of Sheet Steel.**—The report of the researches carried out during 1904 5 by the holders of the Andrew Carnegie research scholarships has just been issued by the Iron and Steel Institute. The subject of the magnetic and electric properties of various kinds of sheet steel and steel castings is dealt with by Messrs. G. Dillner and A. F. Enström, of Stockholm. The chief object of the investigation was to study the influence of chemical composition and of manufacturing methods on the materials used in electrical engineering work, more especially in dynamo and transformer construction. In summing up the authors deal with the influence exercised by various elements. The fact that an increase of the carbon percentage implies a corresponding increase of the coercive

Digitized by Google

force and of the hysteresis energy loss has been very distinctly borne out by the figures obtained for the sheet metal. The increase of the coercive force and the Steinmetz hysteresis coefficient have been found to follow a straight line within the range of a carbon percentage of ·5 per cent. Thus it is obvious that a small amount of carbon is favourable in sheets used in armature cores and transformers. As regards the cast steel, however, it seems to the authors that there ought not to be any inconvenience whatever involved in the increase of the carbon percentage, so far as is shown by the present researches. With the very highest percentage met with in the cast steel employed (carbon = about ·30 per cent.) the authors consider the values of the maximum induction and of the permeability at the induction normal in field poles perfectly satisfactory, whilst the hysteresis properties of the pole material are comparatively unimportant. A high percentage of carbon also produces an increase in the electrical resistance, an effect which must be considered advantageous. An increase of silicon has been found to be accompanied by a quite noticeable increase of the coercive force and of the hysteresis energy loss, whilst the maximum induction does not seem to be influenced to any noteworthy extent. As the hysteresis loss is thus so largely increased by reason of the presence of the silicon—a disadvantage by far outweighing the corresponding gain as regards electric resistance—the conclusions to be drawn are that any addition of that element in making the steel ought, as a rule, to be avoided in the case of sheet material. As to the influence of a similar increment of silicon in cast steel, the results have proved to be anything but unsatisfactory, the electric resistance being quite noticeably increased. It has been stated that an addition of aluminium quite noticeably reduces the hysteresis loss, whilst it increases the electric resistance, and thus reduces at the same time the eddy-current loss. It has been found, too, that an addition of aluminium will reduce the maximum induction and the permeability for ordinary saturation values. The general conclusion is, therefore, that an addition of aluminium improves sheet material which is to be used for constructing dynamos. As regards cast steel the matter is different. With such a high percentage of aluminium as is required in order to increase the electric resistance to an effective degree, the magnetic properties will be too much affected, and the authors point out that the usefulness of aluminium in cast steel is, to say the least, questionable. It is of interest, however, to notice the results obtained from the researches on cast-steel rods containing both silicon and aluminium. In this case low hysteresis losses are found, attributable, probably, to the influence of aluminium, whilst the influence of this element on the permeability and maximum induction seems to be neutralised by the addition of silicon. The addition of silicon and aluminium together seems thus to tend towards a general improvement of the magnetic properties.

**An Electrolytic Switch.**—At the recent meeting of the American Electro-Chemical Society a paper on this subject was presented by Mr. W. S Horry, who first pointed out that the various properties of the aluminium cell are, apart from its assymetric peculiarity, that it presents a high resistance to the passage of an electric current, it possesses capacity, and it leaks. The author suggested a method, described below, whereby these qualities may be utilised for the prevention of the arcs that occur when a current possessing inductance is interrupted. As all continuous-current circuits possess more or less inductance, the voltage rises across the break when a switch carrying such a current is opened. This not only causes an inconvenient flash at the switch, but endangers the insulation of the circuit. If, however, a suitable electrolytic cell be inserted across the break and the circuit then broken, there is no flash at the switch, and the increased voltage will force a current through the cell instead. The insulation of the cell breaks down, but quickly re-establishes itself. After that the mains may be entirely disconnected without any spark. To obtain the best results in this way, an electrolyte for the cell should be chosen that substantially shuts off all current at the working voltage, but allows considerable leakage to occur with any increased pressure—a cell that has a critical voltage a little above the line voltage. For small cells intended for use on circuits of 1 h.p. or less at 110 volts the matter is not of much importance. The plan of the circuits is simply illustrated in Fig. 1. The circuit is represented as a

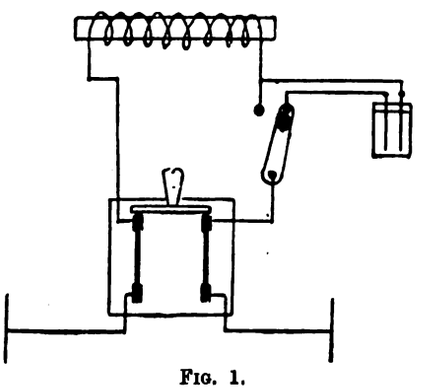

FIG. 1.

line containing an electromagnet, there is a double-pole switch for the line, a rheostat contact, and an aluminium cell. If the switch is closed, no current will flow except that which leaks through the cell, but if the rheostat arm is moved to the left, then the full current will pass. To shut off the current, the rheostat is returned to the position shown and the switch opened. In addition, the cell possesses capacity, and, if it be a large one intended to suppress a powerful arc, there will be a spark at the arm contacts when the terminals of the cells are connected. To close the circuit sparklessly, the rheostat must be moved before the switch is closed. If the arm be moved first, both in opening and closing the circuit, there will be no spark at make, due to capacity, and no arcing at break, due to self-induction. The author exhibited a switch which operates in this way with one movement of the switch handle. There are three knives to it, the middle one having a more extended movement than the other two, so that it operates always in advance of the outer blades.

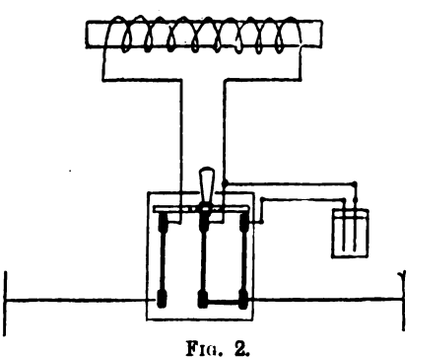

FIG. 2.

Fig. 2 gives a diagram of the connecting circuits. The author described various cells of different sizes, which he has devised for various purposes. For long continued and rapid use a larger cell is necessary than for infrequent use, so that the heat generated by the continued arcing through the cell shall be radiated more rapidly. We are indebted to the *Electrical World* of New York for the above condensation.

## THE CURTIS STEAM-TURBINE.

The description of this turbine from the pen of Mr. F. Samuelson which appeared in our issue for Feb. 19, 1904, will have made our readers conversant with the essential feature of the Curtis type of steam-turbine. On Friday last we were shown over the Rugby works of the British Thomson-Houston Company, where a large number of these turbines are being manufactured. This visit enabled us to see the many special operations involved in the construction of the parts of these turbines and to gain details as to the latest practice in the design of the same. In the first place, a short *résumé* of the general principles of the turbine will

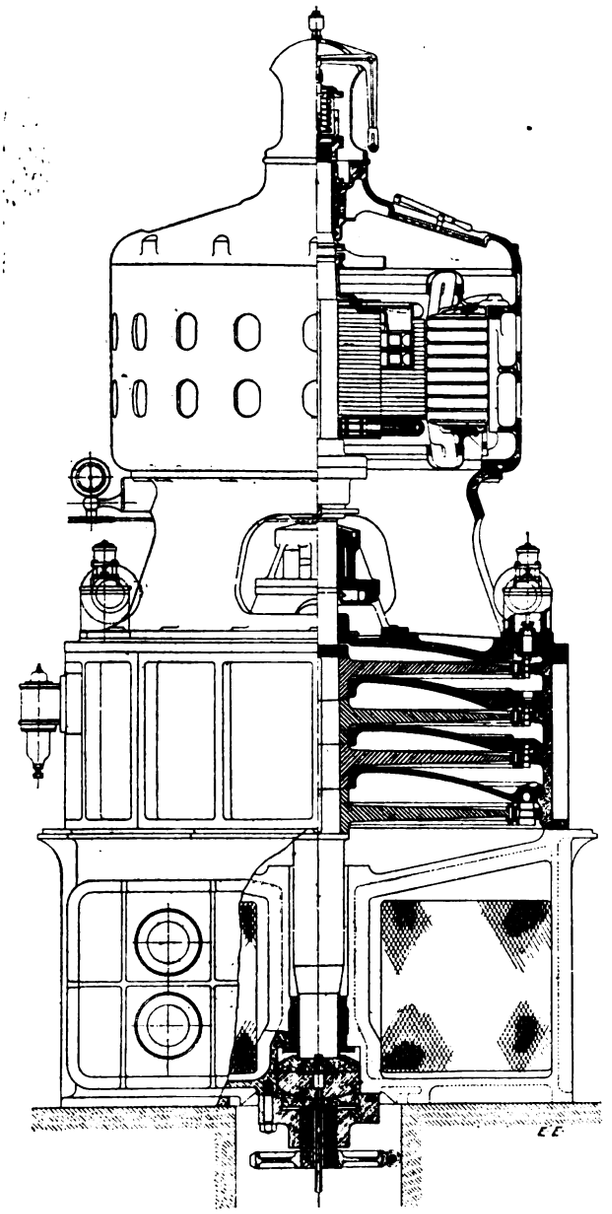

FIG. 1. Section of a Four-Stage Curtis Turbine, with Condenser in Sub-Base.

enable these constructional details to be better appreciated. Thus the Curtis turbine, as shown in section in Fig. 1, is of the "impulse" type, utilising the velocity of steam escaping from a nozzle for its operation, and not the pressure of the steam. Velocity is imparted to the steam through groups of expanding nozzles, so designed as to effectively convert its potential energy into kinetic energy. After leaving the nozzles, the steam passes successively through two or more rings of buckets on the rotating element, interspersed with reversed buckets on the stationary part of the turbine. The function of these stationary buckets or "intermediates" is to redirect the steam received from the rotating buckets so that it will effectively impinge upon the next set of rotating buckets: the steam thus passes through the turbine, rebounding alternately from the stationary to the rotating buckets until it is brought to relative rest. By this means a high steam velocity is efficiently used to impart motion to an element which moves at a comparatively slow speed. The process of expansion through nozzles and subsequent abstraction of velocity by successive impacts with the buckets is generally repeated two or more times, each expansion being designated "a stage." The number of

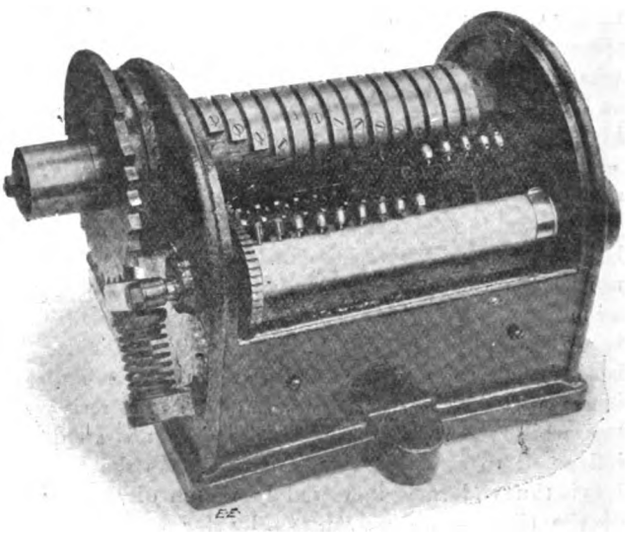

FIG. 2.—Electric Controller for Governor of Curtis Turbine.

stages and the number of rings of buckets in each stage is governed by the degree of expansion, the peripheral velocity of the buckets which is desirable or practicable, and by various conditions of mechanical expediency. Thus the 750-kw. turbine has three stages and the 1,500-kw. machine four stages. Each stage is separated by a diaphragm which is steam-tight, except where nozzles are inserted for the steam to pass into the next stage.

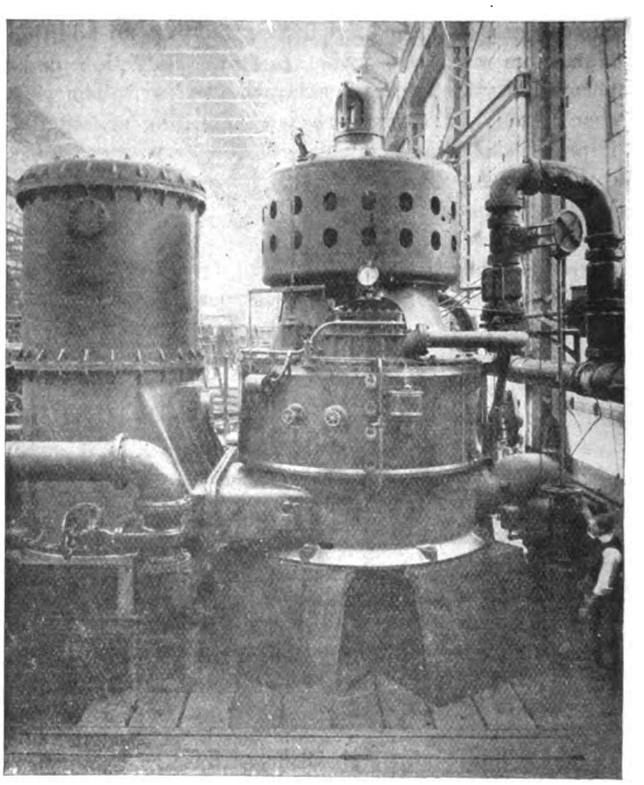

FIG. 3.—View of 1,500 kw. Turbo-Alternator on Test Plate.

One advantage of this system of utilising the velocity of the steam is that the efficiency of the turbine is not so dependent on the mechanical clearance between the fixed and revolving blade as is the case with the pressure type of machine. It also permits of a much more simple system of governing. As the load varies the number of the nozzles which are opened to the steam-chest is varied by the electric governor shown in Fig. 2. The valves over the nozzles

Digitized by Google

are electrically controlled by means of this governor, which thus varies the width of the belt of steam impinging on the first series of revolving buckets. In the earlier forms of Curtis turbines the whole of the governing was done on the first stage. In the case of the 1,500-kw. turbine which we saw on trial last Friday the nozzles of the second stage were also governed as the load varied. This was effected by means of a steam relay which automatically closed a certain number of the second-stage nozzles when the load fell below a predetermined value. This relay was actuated from the underside of certain of the first-stage valves, and ensured that when these valves were closed those in the second stage would also be shut. This relay is seen in Fig. 3 at the right-hand side of the four inspection openings. The two hand-wheels which are seen at the left-hand side of the same can be used to close a certain number of the third-stage nozzles if the turbine has to be run for a considerable period at light load. By these means the work taken from the steam can be so divided between four stages of the turbine as may be found most economical. It may be stated here that these large turbines are giving excellent results from a steam-consumption point of view, and are more than fulfilling the guarantees which have been given for them. The great feature, however, of the construction of the Curtis turbine lies in the mechanical strength provided in all the parts, and to this the designers have paid great attention.

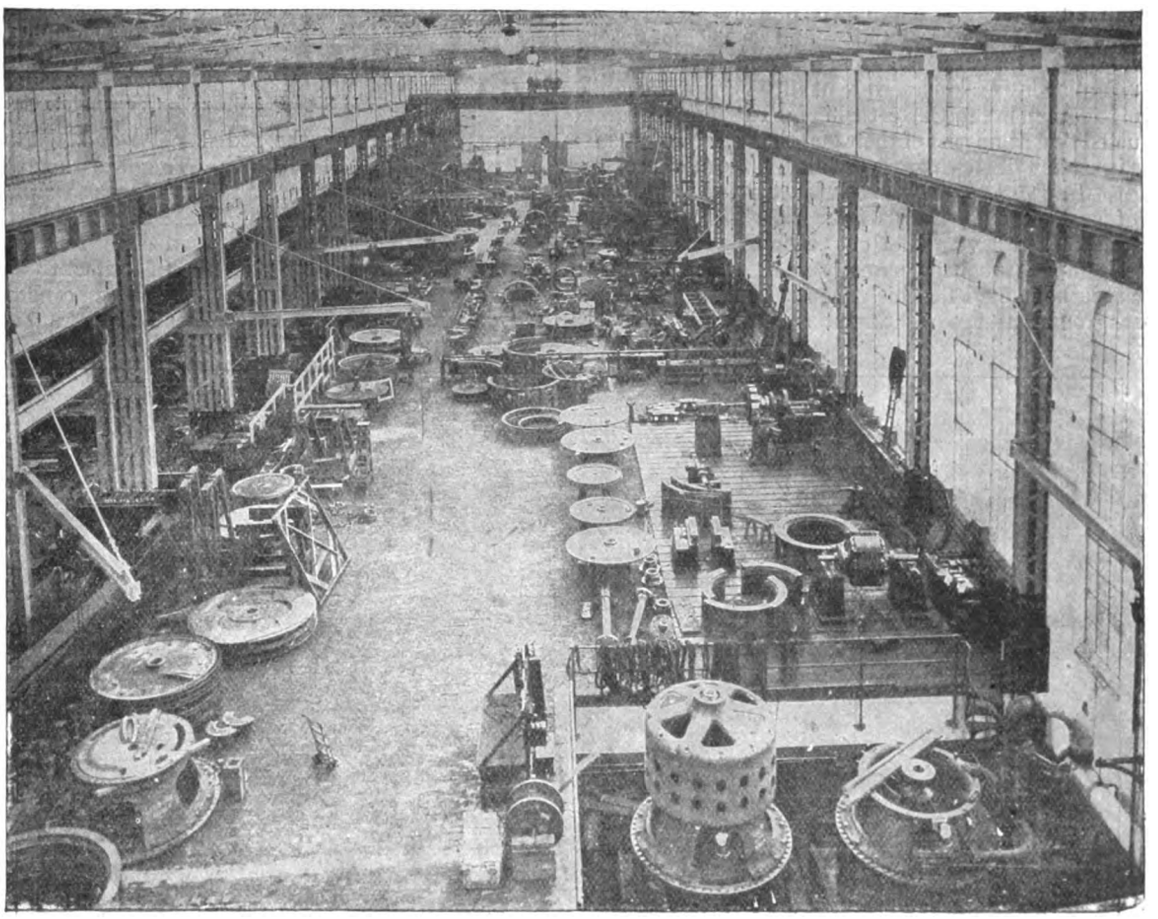

FIG. 4.—One of the Shops of the British Thomson-Houston Company at Rugby in which the Curtis Turbines are manufactured.

Of first consideration in this problem is the revolving part of the turbine, which has to carry the blades for each of the different stages. The firm have adopted a high-grade nickel steel for the turbine shaft, in order to secure not only strength, but rigidity. At the time of our visit we saw one of these shafts being turned in a lathe with a self-hardened steel tool. The stiffness of the turnings, which were coming away from the tool at a high temperature, gave a good idea of the quality of the material from which the shafts are made. The hubs, carried on the spindle, and from which the turbine blade rings are supported, are of cast steel. The details of these can be seen in Fig. 1. Perhaps the most interesting feature in the construction of the turbine is the process by which the turbine blades are machined out of the solid. The rings of rolled steel which are bolted to the turbine hubs are first turned all over and fitted to the same. The outside edge of each ring has a central projection left, which is afterwards used for riveting over a steel strip which unites the ends of each blade. The process of machining out the blades from the solid ring is performed on four machine tools which have been designed specially for the purpose. In the older pair of these machines, a tool the exact width of the steam passage between two adjacent buckets is constrained to move round in a path, one portion of which exactly coincides with the contour of this inter-bucket space. During the other portion of its movements the tool is brought back beyond the edge of the disc so as to clear the same on what may be termed the return stroke. With these machines, which are most ingenious in their construction, only one definite form of bucket can be cut.

In the two newer machines the tool does not move continuously round in one direction, but to and fro over a predetermined path, the contour of which can be varied. With these machines, therefore, the shape of the buckets in each stage can be considerably altered, in order to secure the best economy with a given velocity in the steam escaping from the nozzles. In this machine the tool is slightly withdrawn on the return stroke so as to clear the surface which is being worked. The gear which give the different motions to the tool in order to keep it moving in the desired path and its edge always at right angles to the same are most ingenious. Compressed air is used to give certain of the motions. After the space between two buckets has been machined out there remains but little to be done by hand labour. The edges of the buckets are, however, finished up to a feather edge by filing. A steel band with holes in it is then placed over the projections at the top of the buckets which were turned on the edge of the original ring. These projections are riveted over, and the steel strip then prevents the steam passing through the buckets from spreading radially. The edge of this steel strip is turned and left slightly wider than the blades themselves. Thus, if for any reason the

Digitized by Google

clearance should be varied, this edge will run on a corresponding continuous surface at the root of the fixed blades. The blades are thus prevented from engaging one with the other. In fact, the process adopted in adjusting the clearances between the two revolving discs in each stage and the upper and under sides of the fixed blades is to raise the spindle until they are heard to touch, then to lower the spindle until contact again occurs, and then to fix the working position midway between these two extremes. The construction, therefore, is such that no damage is done to the turbine should the revolving parts come in contact with the fixed ones. The blades on the case are usually made of gunmetal, and are cast in sections. The blades are then filed up by hand, but with the castings we saw very little filing was needed.

Another interesting feature in the machine work on these turbines was that of forming the expanding nozzles in the diaphragms between the different stages. The sizes of these nozzles increases naturally in each stage owing to the expansion of steam on its way through the turbine. The general process may be briefly described as that of drilling first an inclined hole through the diaphragm, and then riming out the one end of this round hole into an oval section. In this way the size of the orifice is gradually increased, allowing the steam to expand as is required by the principle adopted in the Curtis turbine. These orifices are so constructed that at no part of their length is there any sudden change in section likely to cause eddying in the steam passing through. In order to secure absolute truth in the revolving parts of each turbine, the surfaces to which the bucket rings are attached have a final cut taken off them after the cast-steel hubs have been actually mounted on the shaft. A special lathe is used for this purpose. It can be seen in the background at the right-hand side of Fig. 4, which shows a view of the main shops in which the turbines are constructed. The other mechanical details are equally worthy of special notice, but several of these are described in our previous article referred to above. With the newer types of turbines it is frequently arranged that they shall stand directly on the condenser casing, as is shown in Fig. 1. This brings the condenser very close to its work, and prevents loss of vacuum due to leaky connecting pipes.

While the turbine attracted most attention, we were also greatly interested in some alternators which were going through the shops, and which are to be driven by these turbines. In these the armatures were fixed and the field-magnet systems revolved. In Fig. 5 we show a view of a six-pole field for a three-phase alternator. The whole of the iron circuits in this field are laminated. The steel

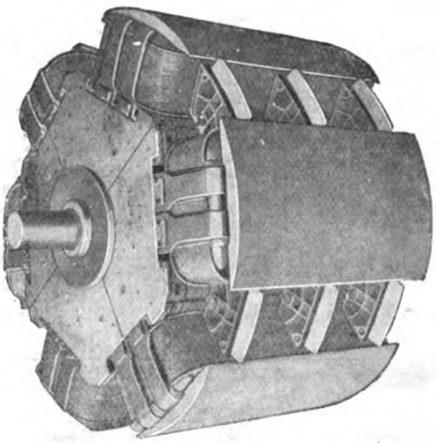

FIG. 5.—Revolving Field Magnet of Alternator for coupling to Curtis Turbine.

laminations forming the radial poles and pole-shoes are built up and riveted together. They are then secured by long wedges into dovetailed recesses in the laminated yoke plates, which are clamped up on the shaft. The field coils are usually of copper strip wound edgewise, with insulation between adjacent turns. In order to resist the centrifugal strains on this, special phosphor-bronze stirrups are placed round the ends of the coils where the same are not supported by the projecting pole-pieces. These phosphor-bronze stirrups, of which there are two at either end of each coil, are also drawn down by wedges passing through the end plates of the yoke. Between adjacent field-magnet coils three or more wedge-shaped castings are secured, in order to keep these coils rigidly clamped up. On the outer edge of each of these clamps an inclined vane is constructed, which has the following object. As

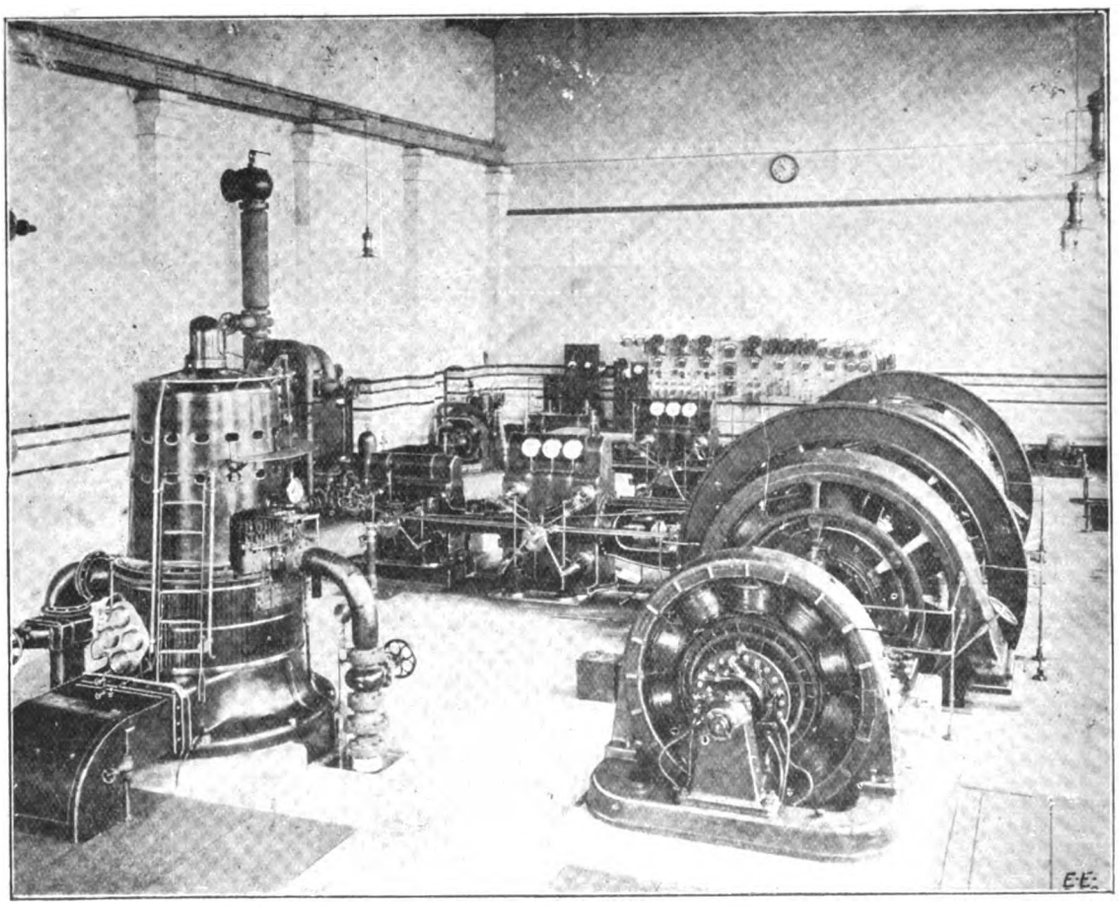

FIG 6.—The Engine Room at the Rugby Power House, showing 750-kw. Curtis Turbine.

Digitized by Google

the field-magnet systems revolve, these vanes are so inclined as to force air downwards and out of the bottom of the alternator casing. This secures a downward draught, and prevents steam or heat from the turbine passing up into the alternator. After the field-magnet system has been assembled, it is run for a short time at about 25 per cent. over normal speed, in order that all the parts may take up their final positions before any attempt is made to accurately balance the system. This balancing not only of the field-magnet system, but also of the revolving turbine parts, is naturally carried out by a series of trials run while the balance weights are being added.

The Curtis turbine was first developed by the General Electric Company in America, and the aggregate output of the contracts secured during the first three years was about 600,000 h.p. The British Thomson-Houston Company, while drawing on the experience of the American company, have also taken steps to improve the turbine when manufacturing it at Rugby. They have secured orders aggregating about 32,000 h.p. for turbines, which are either in course of construction or actually installed. Those at work are scattered throughout the United Kingdom in various electric light and power distribution stations. The general impression left by our inspection last week was that the Curtis turbine would, by reason of its construction, have a longer life and stand rougher treatment than a reciprocating engine of the same output.

## NOTES ON THE THEORY AND TESTING OF THE POLYPHASE INDUCTION MOTOR.

BY W. ROGERS.

*(Concluded from page 665.)*

Before an induction motor leaves the "shops," to ensure satisfactory working, it is submitted to an exhaustive series of tests. For the purpose of detecting defects in the magnetic circuit due to faulty design, or mechanical causes, saturation tests are required with the motor running light, and also with the rotor locked, and to obtain an insight into the true performance of a motor it is necessary to know (1) magnetising current at normal voltage; (2) no-load loss; (3) inductive component of the volts—a speed curve will also be required. The magnetising current and no-load loss are obtained by running the motor light at voltages varying from 5 to 125 per cent. of the normal voltage and taking readings of watts, amperes, and volts. If these results are plotted, having the watts and amperes as ordinates and the volts as abscissæ, the resultant curves will represent the running saturation. The inductive component of the volts from which is deduced the inductive leakage, is obtained from data given by the locked saturation curves. These curves are obtained by locking the rotor and applying varying voltages up to 150 per cent. of the normal volts, readings being taken of volts, amperes, kilowatts, and torque. These results when plotted give the required curves. The speed curve is obtained by running the motor on a brake load varying from quarter load to 50 per cent. overload at normal voltage, which is kept constant, readings of volts, amperes, watts, speed, and torque being taken. If the values of amperes and speeds be plotted, using the amperes as abscissæ, the result is a speed curve for different values of load. From the data given by these three tests, it is possible to separate the different losses occurring in the motor, and draw up complete curves showing its performance.

When taking the speed curve of large motors it is not always possible to obtain accurate wattmeter readings of the motor input, the apparent watts (amperes × volts) being only measured. As it is necessary to know the power factor, in cases where it cannot be obtained from the value of true watts ÷ apparent watts, it must be calculated from the total iron loss in the following manner. It is first necessary to find the value of the inductive component of the volts per ampere of current input (taken from the speed curve), and this may be calculated from the information given by the locked saturation curves. If any current C be taken on the ampere curve, and also its corresponding value of V volts, then the apparent kilowatts = C × V ÷ 1,000. Note the real kilowatts taken off the kilowatts curve for the same value of V volts, then the inductive kilowatts

$$= \sqrt{\text{apparent KW.}^2 - \text{real KW.}^2};$$

also inductive volts $= \sqrt{\text{apparent KW.}^2 - \text{real KW.}^2} \div C.$

$\therefore$ Inductive volts per ampere

$$= \sqrt{\text{apparent KW.}^2 - \text{real KW.}^2} \div C^2.$$

Then the total value of inductive volts for any particular value of current input, I, is given by

$$\frac{\sqrt{\text{apparent KW.}^2 - \text{real KW}^2}}{C^2} \times I.$$

The inductive leakage expressed as a percentage

$$= \frac{\dfrac{\sqrt{\text{apparent KW.}^2 - \text{real KW.}^2}}{C^2} \times I}{\text{normal voltage}} \times 100$$

and the value of this quantity in any particular case represents one part of the iron loss. From the running saturation curve read off the current $C^1$ at normal voltage which represents the magnetising current, then this current expressed as a percentage of the value of current input

$$I = \frac{C^1}{I} \times 100.$$

As the total iron loss expressed as a percentage = % inductive leakage + % magnetising current, then the total % inductive loss

$$= \left( \frac{\dfrac{\sqrt{\text{apparent KW.}^2 - \text{real KW}^2}}{C^2} \times I}{\text{normal voltage}} \times 100 \right) + \left( \frac{C^1}{I} \times 100 \right)$$

For the purpose of illustration, suppose the value of this quantity = 38·3 per cent., then the power factor for the same value of current input, I, may be easily obtained. Now the power factor is the ratio of the real kilowatts to the apparent kilowatts, and when there is an inductive loss this ratio is always less than unity. The power factor is found from the right angle relation in a triangle whose three sides are expressed in percentage values, as the power factor is usually expressed as a percentage. In a right-angled triangle the base will represent the power factor, and the vertical side will represent the total percentage inductive loss, which in this case = 38·3 per cent., and this represents the percentage value of the wattless component. In this case we have power factor $= \sqrt{100^2 - 38.3^2} =$ 92·5 per cent.

Having obtained the power factor the other quantities may be easily calculated. The apparent horse power $= \frac{I \times \text{normal voltage}}{746}$; also real horse-power = apparent horse-power × power factor; real watts = real horse-power × 746.

At this point it will be necessary to know the copper loss in the primary winding, but before this can be calculated the primary resistance must be obtained. The formula for calculating the watts lost in a two-phase or three-phase winding $= \frac{C^2 R}{2}$, and the accuracy of this formula may be proved as follows:

Considering, first, a two-phase winding, let C = total current, then $\frac{C}{2}$ = current in each phase.

$$\text{Watts lost in each phase} = \left(\frac{C}{2}\right)^2 \times R = \frac{C^2}{4} \times R.$$

$$\therefore \text{Watts lost in both phases} = 2 \cdot \frac{C^2 R}{4} = \frac{C^2 R}{2}.$$

With a three-phase winding, if C = total current, then $\frac{C}{\sqrt{3}}$ = current in each phase, and

$$\text{Watts lost in each phase} = \left(\frac{C}{\sqrt{3}}\right)^2 \cdot \frac{R}{2} = \frac{C^2}{3} \times \frac{R}{2}.$$

$$\therefore \text{Total loss in the three phases} = 3\left(\frac{C^2}{3} \times \frac{R}{2}\right) = \frac{C^2 R}{2},$$

Digitized by Google

In each case R represents the mean value of the primary resistance, which $= \frac{r^1 + r^2 + r^3}{3}$ in a three-phase winding, where $r^1$, $r^2$, and $r^3$ = resistances of each phase.

To allow for the increase in resistance due to heating, it is usual to add on 10 per cent. to the $C^2R$ loss in the primary winding. The other loss to be taken into account is the "no load" loss, which is taken at "normal voltage" from the watts curve of the running saturation.

Total losses are therefore = primary copper loss + 10 per cent. + no-load loss. Then real watts = real horse-power × 746 − total losses.

This quantity "will be further reduced owing to the slip" of the motor. We have motor synchronous speed = alternations ÷ number of poles. Also slip = synchronous speed − motor speed. If the synchronous speed be taken as 100 per cent., then percentage slip

$$= \frac{\text{synchronous speed} - \text{motor speed}}{\text{synchronous speed}} \times 100.$$

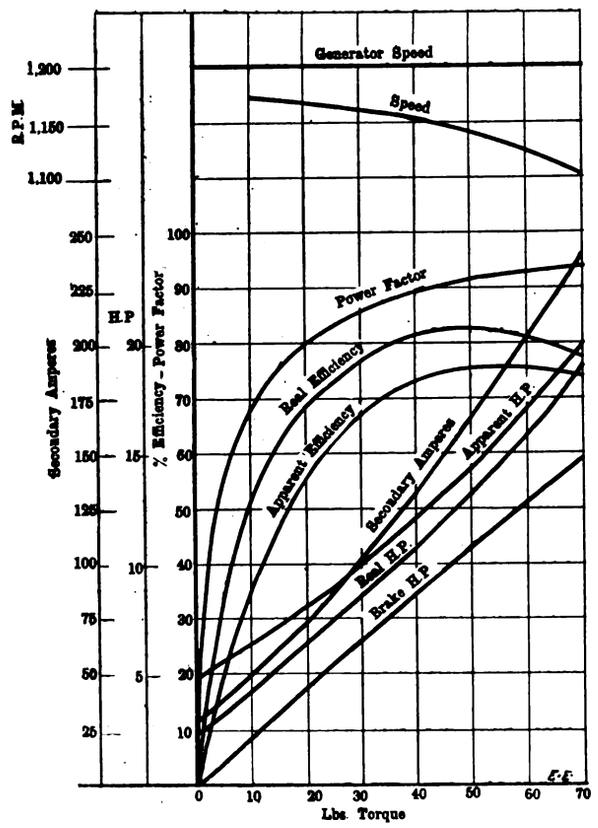

FIG. 5.

Now, $\frac{\text{watts output}}{\text{real watts} - \text{losses}} = \frac{\text{motor speed}}{\text{synchronous speed}}$

$$= \frac{\text{synchronous speed} - \text{slip}}{\text{synchronous speed}}.$$

$$\therefore 100 - \% \text{ slip} = \frac{\text{motor speed}}{\text{synchronous speed}} \times 100.$$

$\therefore$ Watts output = real watts − losses × 100 − % slip.

Brake horse-power = watts output ÷ 746.

Apparent efficiency = brake horse-power ÷ apparent horse-power.

Real efficiency = brake horse-power ÷ real horse-power.

$$\text{Torque} = \frac{\text{brake horse-power}}{\text{speed} \times \cdot 00019} = \frac{\text{brake horse-power} \times 5{,}252}{\text{speed}}$$

Also brake horse-power = speed × torque × ·00019.

Having worked out the quantities mentioned above, if the values of real and apparent efficiency, horse-power, power factor, and speeds be plotted as ordinates, with the corresponding values of torque as abscissæ, the resultant curves will show the actual performance of the motor.

It is possible to find the efficiency direct from the speed-torque curve in the following manner: If the torque is measured at 1ft. radius, note the speed for any particular value of torque. Then

Horse-power developed = torque × speed ÷ 5,252, or

Power in watts = torque × speed ÷ 7·04; also

True power expended = power developed in watts + iron, copper, and friction losses.

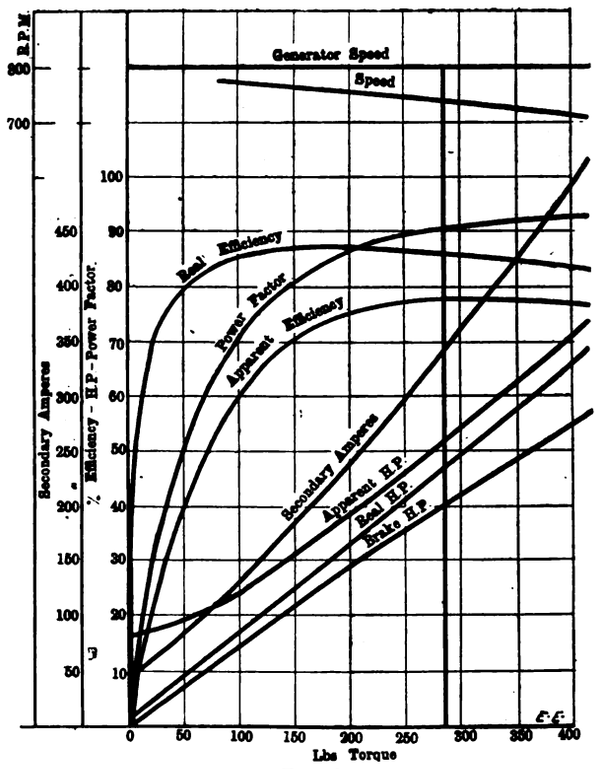

FIG. 6.

The starting torque of an induction motor may be varied, and in practice is generally between one and a half and three times the full-load torque. The value of the

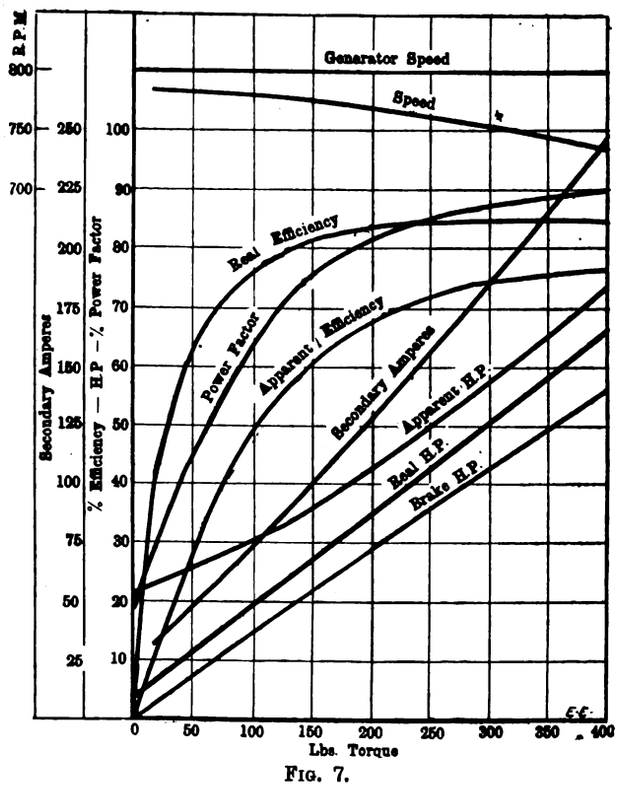

FIG. 7.

starting torque may be found by reading off the locked saturation curve the no-load torque at normal voltage; also read off the power curves the value of torque at the full-load point on the brake horse-power curve. Then no-load torque ÷ full-load torque represents the value of the starting torque as compared with the full-load torque.

Digitized by Google

The value of the slip at full load, expressed as a percentage of the synchronous speed, is found by reading off the motor speed curve (on the power curve) the drop in speed below synchronous speed at the full-load point. This drop in speed represents the slip of the motor. Then percentage slip = slip ÷ synchronous speed × 100.

Through the kindness of the British Westinghouse Company, I am able to show three typical performance curves (Figs. 5, 6, and 7) of different sizes of three-phase motors having wound rotors. This type of motor is designed for variable speeds, and is essentially suitable for use when loads have to be carried at reduced speeds, such as with hoist and elevator work. The variable-speed characteristics are obtained by introducing a variable resistance into the "secondary circuit," the slip or drop in speed being directly proportional to the resistance of the rotor circuit. For a given current the torque and power taken from the supply circuit are independent of the speed, and the loss at a reduced speed is proportional to the reduction in speed. When speed variation in an induction motor is obtained by varying the primary voltage, the $C^2$ R loss occurs in the rotor circuit itself. In this case a large reduction in speed will result in a high copper loss. When speed variation is obtained by inserting a variable resistance in the rotor circuit, as in the type of motor under consideration, a large part of the "secondary loss" is dissipated in the external resistance. This type of motor is, therefore, admirably adapted for handling loads at reduced speeds for long periods of time. Its power factor is independent of the speed, and is constant for any given torque. It has the advantage of a heavy starting torque with a minimum current, and runs with small slip when up to speed and with constant torque; the efficiency varies with the speed. In Fig. 8 is shown a photograph representing this type of motor operating a "mine" hoist. The compact appearance of this "hoist" is a good illustration of but one of the many advantages of electrical working in colliery plants.

A characteristic of the induction motor which is regarded as a great disadvantage when compared with the characteristics of the synchronous motor, is the fact that the current taken by it is always a lagging current, but with induction motors of larger size this out-of-phase current is small, and may be considered constant for different values of load. The synchronous motor also takes an out-of-phase current which may be either lagging or leading, depending upon the field excitation of the motor, and as this out-of-phase current is constantly varying it has a very disturbing effect on the supply system. As the lagging current taken by an induction motor is almost constant, the disturbing effects it has on the system are much less. Another great advantage which the induction type has over the synchronous motor is its satisfactory performance in cases of emergency, such as momentary interruption of the supply circuit or temporary overloads. For these reasons, and also for the simplicity and reliability of its operation, the induction motor has taken a leading place in connection with power-transmission plants.

In conclusion, the writer's thanks are due to the British Westinghouse Company for their kindness in supplying him with the curves and photograph illustrating this article.

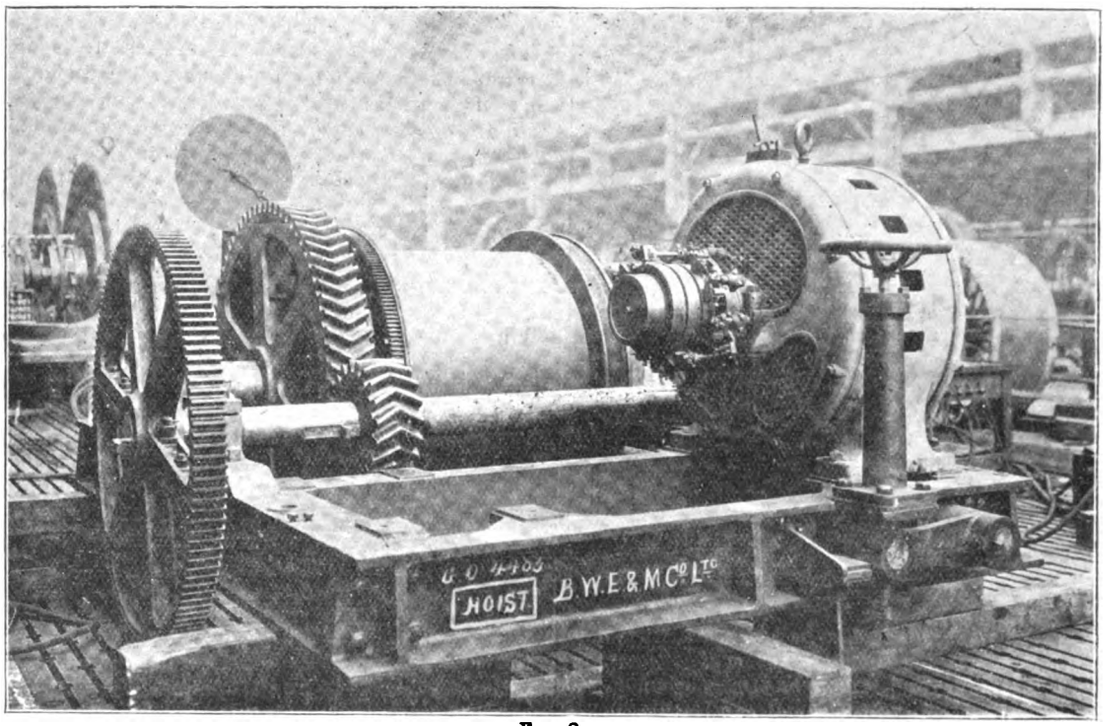

FIG. 8.

## DENNY AND JOHNSON'S TORSION METER.

We are indebted to Messrs. Kelvin and James White, Limited, of Glasgow and London, for some interesting particulars of a new form of torsion indicator recently introduced by them, and by means of which the torsion of a revolving shaft may be easily ascertained, thus enabling the horse-power transmitted to be accurately calculated. Having regard to the increasing use of turbines for marine work, the advent of this instrument is certainly opportune. It is the joint patent, we understand, of Mr. Archibald Denny and Mr. Charles Henry Johnson, the last-mentioned gentleman being an electrical engineer with Messrs. William Denny and Bros.

The accompanying diagram (Fig. 1) shows the general arrangement of the apparatus as applid to turbine-driven shafting. On the shaft the torsion of which it is desired to measure are fixed at a suitable distance apart two light gunmetal wheels, A and B. On each wheel is mounted, as shown, a permanent magnet, the projecting pole of which is made V-shaped in order to produce a dense and definite magnetic field at the point. Underneath the magnets, and set concentrically with the wheels and shaft, are fixed two inductors, A and B, each of which consists of a quadrant-shaped piece of soft iron carried on a gunmetal stand provided with suitable levelling screws. On each piece of iron are mounted a number of separate but similar windings of insulated wire, there being a certain suitable number of windings per unit of circumferential length of the iron. There is in conjunction with the inductors a recording box, in which are mounted two series, A and B, of contact studs, around which are fixed scales. In connection with the series of studs two contact arms, A and B, are arranged, by means of which electrical connection may

Digitized by Google

be made at will between any desired stud of a series and its contact arm. There is in series A a stud for every separate winding in the inductor A, and in series B a stud for every separate winding in the inductor B, each stud being connected to its particular winding by means of a separate wire, all of which are contained in the multiple cables, A and B. The remaining ends or returns of the windings on the inductors A and B respectively, are all connected by means of two common wires to the contact arms A and B respectively. Included in each of these two

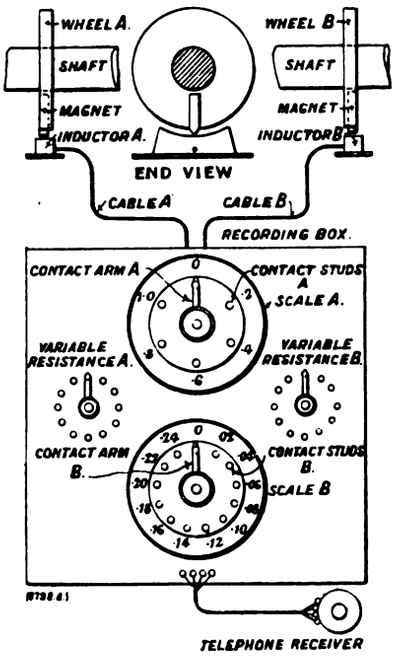

FIG. 1.

circuits is a variable resistance (by means of which the strength of the current flowing in the circuit may be adjusted as desired) and one winding of a differentially-wound telephone receiver. The scale A is divided into five equal parts, there being six separate windings in the inductor A, and thus six studs in the series A; the length of the scale thus represents the circumferential length occupied by all the windings on the inductor, each subdivision representing the distance between neighbouring windings, which is usually 0·2in. The scale B is divided into 13 equal parts, there being 14 separate windings on the inductor B, and thus 14 studs in the series B. The length of the scale, as before, represents the circumferential length occupied by all the windings in the inductor, the distance between neighbouring windings being represented by one division of the scale. The usual distance between neighbouring windings in inductor B is 0·02in. The steel in connection with the inductor at the turbine end of the shaft is set so that the magnet fixed to it is exactly above one or other of the two end windings in the inductor; the correct end winding to set the magnet to being that one from which the magnet will travel towards the other end winding when the shaft rotates. The wheel in connection with the other inductor is also set so that its magnet is exactly above one of the two end windings in the inductor, the correct end winding to set the magnet to in this case being that one from which the magnet will travel in the opposite direction of the other end winding when the shaft rotates. To facilitate the accurate and easy setting of the magnets above their respective windings, lines are cut in the tops of the inductors exactly above the end windings, and the magnets are set to these lines. When the shaft rotates without transmitting power, a current of electricity is induced in the end or zero winding of each inductor, the contact arms being first placed in contact with the end or zero stud in each series. These two separate currents each traverse their respective circuits, passing in each case from the inductor winding, in which they are induced, to the respective zero studs, to which these windings are connected, thence by way of the respective contact arms, resistances, and telephone receiver windings back to the inductors again. The connections to the receiver windings are so arranged that the effects of the two separate currents flowing therein are in opposition, and thus neutralise each other's effect on the receiver when the strengths of the two currents flowing are exactly equal at the same instant. By means of the variable resistances in each of the circuits the currents are made equal in strength, and then so long as the shaft transmits no power, and is thus subject to no torsion, no sound will be heard on listening at the receiver, since the currents induced in the zero windings of the inductors have been equalised and are both induced at exactly the same instant. When transmitting power the shaft is subject to a certain torsion or twist, which causes the zero winding of the inductor next the turbine or engine to be excited in advance of the other by the amount of the torsion of the shaft. A loud ticking sound will then be heard in the receiver, as the currents no longer neutralise each other. Contact arm B is then shifted from stud to stud until the position of greatest silence in the receiver is once more obtained. When this position is found, the reading on the scale B opposite the contact arm represents the circumferential measurement of the angle of torsion of the shaft at the radius of the inductor windings. A current equal in strength at the same instant to that induced in the zero winding of inductor A is now being induced in that winding of inductor B which is in connection with the contact arm B. The scale reading thus represents the displacement of one magnet with regard to the other due to the torsion of the shaft. In the event of the torsion being found to be too great to be measured on scale B alone, contact arm A is shifted from stud to stud until a reading can be obtained on scale B, the torsion reading being equal to the sum of the readings on scales A and B. The reading corresponding to any large displacement of one magnet relatively to the other, is thus easily obtained by the combined use of the scales A and B.

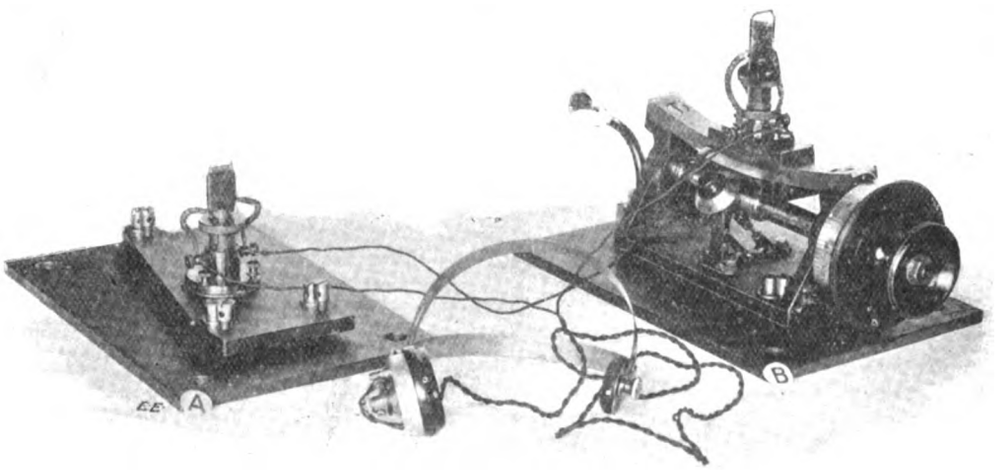

FIG. 2

These instruments were designed and made because, unlike the reciprocating engine, it is impossible to obtain

Digitized by Google

the power by means of indicator diagrams in the case of a turbine, and Messrs. William Denny and Bros. foresaw that if success in speed prediction was to be attained in turbines, some means must be devised for ascertaining accurately the power developed and transmitted from the turbine. They have now been tested exhaustively on no less than 11 of the turbine steamers built by that firm, and have proved entirely satisfactory, an average accuracy of 99 per cent. in the readings taken being easily obtained. The recording box is usually placed in a quiet cabin, as while the sound in the telephone is quite definite for fine adjustments, it is desirable to have as little extraneous noise as possible. A recording machine with a strip of paper may be fitted in this cabin, with a pen for recording the revolutions of each engine by means of electric contacts, and a further pen connected from the watch of the observer on the bridge who is taking the time on the mile, while a third pen marks half seconds from a standard clock. By means of these the observer in the cabin is advised when the ship is on the mile and makes his observations of power quite independently of any advice from the engine-room, the revolutions being recorded at the same

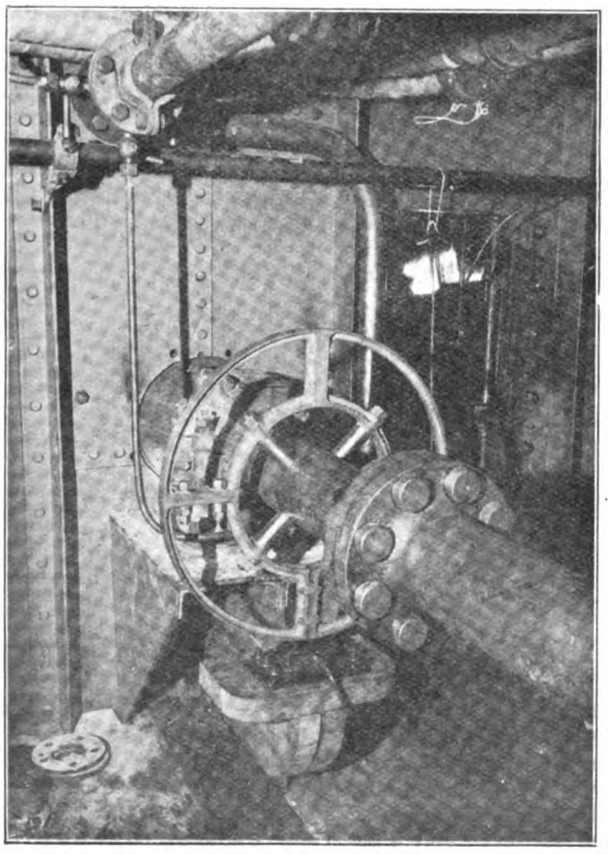

FIG. 3.

time. It is thus practicable to report the result of a run in speed and power within a few minutes of being completed.

Our illustration (Fig. 2) shows the two conductors of a rather different form of torsion meter. In this instrument inductor A consists of a thin soft iron core wound with insulated wire and mounted on a suitable base. Inductor B consists of a similar core and winding on a slider mounted on a quadrant-shaped guide in such a manner that by turning a handwheel the slider carrying the core may be moved backward or forward along the gnide. A telephone receiver is arranged in circuit with the inductors as shown, and each inductor is set beneath a wheel (not shown) carrying a magnet, as in the case of the previously described instrument. To take a reading, the handwheel is moved backward or forward as required until silence is obtained in the receiver. The amount of this adjustment is then noted, and represents the amount of torsion of the shaft. This form of torsion meter is specially suitable for very low rates of revolution, and can be easily arranged to measure the torsion of shafting driven by ordinary reciprocating engines. As the torsion of this class of shafting is variable during a revolution (due to the uneven turning moments of steam-engines), six magnets are employed on each wheel instead of one, and these are spaced equidistant about the circumference of the wheels, and are arranged each in a different parallel plane. The inductors are as shown in Fig. 2, except that there are six separate windings mounted on each inductor base, the six windings on each inductor being arranged in line with the shaft and in the same planes as the magnets carried by the wheels. A switch is arranged by means of which any desired pair of windings on the two inductors may be connected in circuit with the receiver at a time, and, as in the previous case, resistances are provided for adjusting the strength of the induced currents. By these means the torsion at six different points of the circumference can be easily and rapidly measured consecutively, and from these readings the mean torsion during a revolution is obtained for any constant condition of trial lasting for a short period.

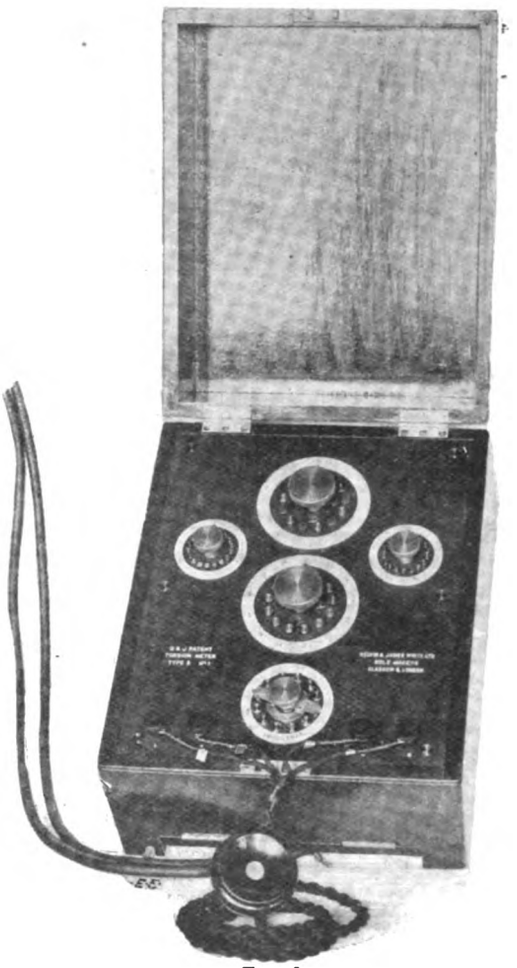

FIG. 4.

An experiment was made with this instrument in the case of a reciprocating engine, whose turning moment was known to be far from regular, and it was found that with six magnets placed equally round the wheel the greatest possible error did not exceed 4 per cent., and by working out a polar diagram of torque and arranging the magnets suitably round the wheel the error involved did not exceed 1 per cent. We need not point out that for laboratory or factory work, in addition to marine work, these instruments should prove extremely valuable.

The further illustrations herewith are from photographs of a set of the first-mentioned type of instruments for turbine work taken on a turbine steamer. Fig. 3 shows the disc fixed at one end of the centre shaft. The disc fixed at the other end of this shaft, and to the remaining shafts, is exactly similar. Fig. 4 shows the recording box. The studs opposite which the letter Z is marked on the scales are for the purpose of testing the accuracy of the zero of the inductors.

From the foregoing description of the "D. and J." patent torsion meters, it will be seen that one of the outstanding features of all the instruments is the total absence of all

Digitized by Google

rubbing contacts. The fact that they have no rubbing contacts and are thus subject to no wear and tear, coupled with the fact that they generate their own current and require absolutely no attention when not in use, make them very suitable for fixing permanently on board ship, thus allowing of a daily reading of the power being taken, which would permit of anything causing loss of efficiency to be at once detected. We understand that Messrs. Wm. Denny and Bros. attacked this problem some 10 or 15 years ago in connection with factory shafting, but without practical success. With the advent of turbines, however, they determined that a proper solution must be found. The instruments described in the foregoing are the result, and Messrs. Denny speak highly of the originality and perseverance of Mr. Johnson in carrying this work to a successful conclusion.

## THE KEY ENGINEERING COMPANY'S EXHIBITION.

A week or so ago we had an opportunity of inspecting an interesting exhibition with practical demonstrations organised by the Key Engineering Company in their showrooms at 38, Deansgate, Manchester. The apparatus on view covered a wide range of subjects, including a Thornycroft four-ton steam wagon, and coming down to such small details as primary batteries. We do not now propose to review the whole of the apparatus which was then open to inspection, but merely to refer to one or two points which struck us as being of special interest. Amongst these was the Ross self-lowering trolley arm, which had additional interest at the time from the fatal accident which had occurred a few days before near Wigan. With this trolley arm the feature is that if the trolley comes off the the wire, it does not remain up in a position which will cause it to engage in the overhead construction. When this is the case it comes to be a question of mechanical strength as to whether the overhead wires will pull the trolley off the car, causing mechanical damage to the passengers, or whether it will pull down the overhead wire, causing electric shocks as well as mechanical. With the trolley arm in question this is prevented by a simple mechanism which ensures the arm coming down to a normal level if it comes off the wire. The details by which this is secured will be gathered from the accompanying illustrations, which show the mechanical construction of this trolley arm. Fig. 1 shows the running position. It will be seen that trolley arm, B, which carries the trolley pole, is pivoted on the pin, C, and carries at one end an adjustable stud, *a*. The trolley head, A, which carries the pole is mounted on ball bearings and turns freely round the standard. E is a rocking lever pivoted at *g*, at one end of which is fitted adjustable wedge, G. F shows the cross-head through which the pull of the spring is applied to the trolley pole. D is a movable support for pin, C, which latter is free to move in the slot shown. The instant the trolley pole leaves the wire the stud, *a*, strikes against the rocking lever, E, causing the point *b* to move up and force D out of position at *d*, which causes it to fall, and with it the trolley pole. This condition of affairs is now seen in Fig. 2, which shows the trolley pole locked clear of the wire until reset. To reset the trolley, the rope is pulled down, the trolley arm now moves about point *e*, and support D is lifted again into position. The rocking lever, E, falls back to the normal position, and the trolley pole is free to move on pin, C, and round the standard, as before. Another good feature in the device is that the arm is also locked in a radial direction so that it cannot swing round and cause damage in that way. The device is one which extended trial should bring into general use.

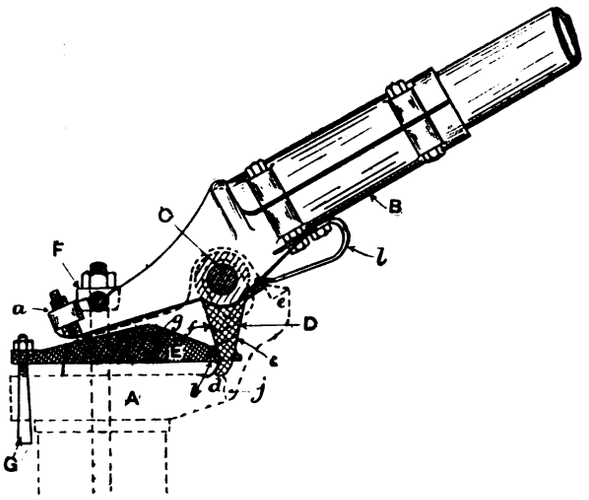

FIG. 1.—The Ross Patent Self-Lowering Trolley Arm in Running position.

Mr. L. Andrews had a good number of his reverse-current circuit breakers on view at this exhibition, and, as usual, he managed to show us one or two new points in the construction of the same. One of these raised the question that, although reverse-current circuit breakers are used in a large number of direct-current stations in the country, it is apparently not generally recognised that the majority of the devices in use are liable to fail to isolate a faulty generator should the fault be equivalent to a direct short-circuit across the brushes. The usual method of testing a reverse-current circuit breaker is to shut the steam off the engine, or to open the field of the generator. Under these conditions almost any reverse-current device will be quite satisfactory on direct-current circuits, as the normal pressure is then maintained across the potential winding on the cut-out, and the current in the series winding is not excessive. Should the brushes of a direct-current generator running in parallel with others be accidentally short-circuited, as is obviously always liable to happen, the conditions are very much more severe, as, in the first place, the potential across the 'bus bars is liable to fall almost to zero, and, in the second place, an enormous reverse current will flow through the series winding, and then will tend to entirely overpower the polarity effect of the combined series and shunt windings, upon which the action of the reverse device is dependent. Attempts have been made in the past to compensate for this defect, of the series current predominating over the potential current, by using a much stronger potential effect than is required to give a satisfactory reverse. This, however, introduces another difficulty, inasmuch as at normal pressure the potential current tends to overcome the series current.

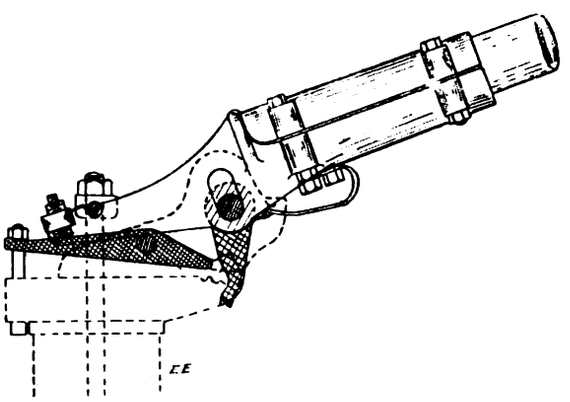

FIG. 2.—The Ross Trolley, Locked.

Several designers have dealt with the difficulty by using permanent magnets instead of magnets energised by a potential winding. Quite a satisfactory relay can undoubtedly be made in this way, but the fact remains that to operate direct-current devices by means of relays involves introducing unnecessary complications and elements of risk. Although the relay may operate satisfactorily, the circuit breaker may not be tripped, in the first place, owing to the contacts of the relay being dirty, and, in the second place, it must be remembered that the current in the tripping coil is often dependent upon the 'bus-bar pressure, and, consequently, if the pressure falls from much below normal, it may be insufficient to trip the circuit breaker. The direct-acting circuit breaker has, therefore, the advantage, in the first place, of greater simplicity, and, in the second place, the heavy current in the series coils assists the current in the potential coil by actively tripping the circuit breaker.

Digitized by Google

In the device illustrated in the sectional sketch (Fig. 3) the series and potential windings are so arranged as to entirely prevent the effect of the current in the one winding predominating over the current in the other. In this construction it is possible to work with the core in the shunt winding highly saturated, and, consequently, if the pressure

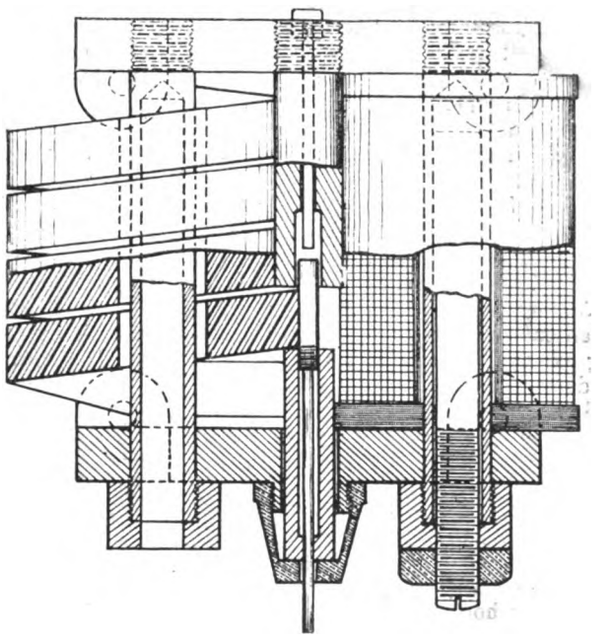

FIG. 3.—Tripping Electromagnets of Andrews' Combined Reverse-Current and Over-load Circuit Breaker.

across the shunt winding drops to something approaching zero, there is still sufficient magnetic force left to cause the device to operate satisfactorily on heavy reverse currents. The characteristic curves A and B (Fig. 4), show the variations in the pull of the tripping core with different generating and motor currents, A with a normal potential and reverse-current device. It will be obvious that if the section of the core in the series winding is appreciably greater than the core in the shunt winding, the latter will become saturated before the former, and consequently some of the flux induced in the series core will leak back through the tripping plunger, thus, with a given excess current, causing this to lift and trip the circuit breaker. It is usually required, however, that a reverse-current circuit breaker shall not be tripped by any amount of forward current, and consequently, to ensure this, the core in the shunt winding should be of heavier section than that in the series in order that the latter may become saturated, and an easy path provided for any flux induced in the series core to return through the shunt core, thus entirely overcoming any tendency to magnetic leakage. To enable the device to be used as a reverse-current breaker only, or as a combined excess current and reverse, the respective cores in the shunt and series windings are made of hollow tubes, and a solid internal core is provided for fitting into either of the hollow cores. Curves A and C (Fig. 4) represent the characteristics of the release with the solid core inserted in the hollow core of the shunt winding. It will be seen that under these conditions there is absolutely no pull on the tripping core with any amount of excess current. Curve B shows the effect of removing the solid core from the shunt winding and inserting it in the series winding. It will be seen that as a reverse-current device the characteristic is not appreciably altered—that is to say, it takes approximately the same reverse current to trip it as with a core in the shunt winding. On the excess-current side, however, the behaviour of the device is entirely altered. The magnetic current leakage, and consequently the pull on the core, increases with the generating current, and will, with a given excess current, trip the circuit breaker. The slope of this curve may be adjusted as desired by varying the position of the core in the series winding.

Another attraction offered by the Key Engineering Company, Limited, to visitors attending their exhibition at Manchester was the opportunity afforded of inspecting the laying of a portion of the 34 miles of fibre conduit now

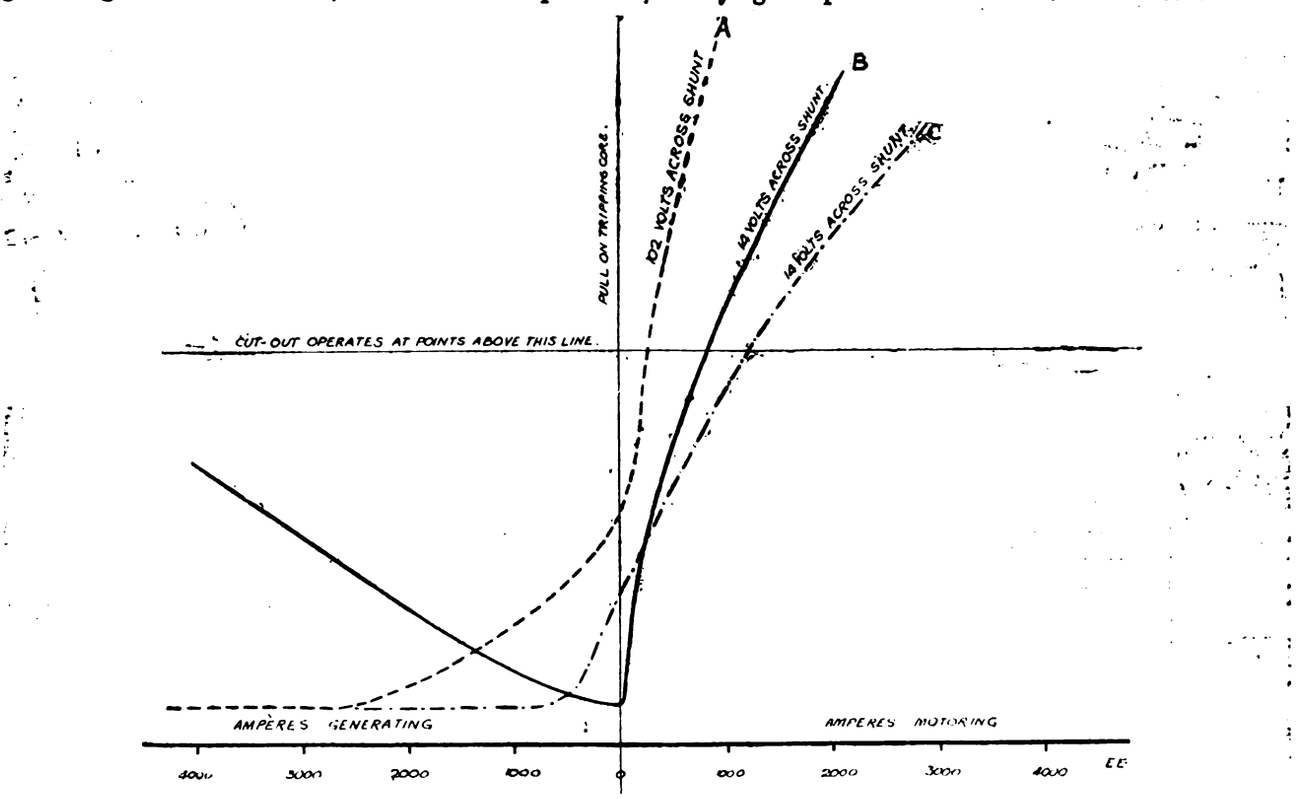

FIG. 4.—Performance Curves of Andrews' Combined Reverse-Current and Over-load Circuit Breaker. The dotted curves are the core set to act as with reverse current only. The full curves show action with core set for combined reverse and over-load tripping.

of 100 volts across the shunt winding, and B with a potential of only 14 volts across this winding. It will be seen that even with a drop of potential of 85 per cent. the reverse current required to operate the cut out is not very much greater than with a normal potential.

An interesting feature of this device is that it may, with a slight alteration, be used as a combined excess-current

being installed by the Manchester Corporation. The accompanying photograph (Fig. 5) was taken during the process of laying a 60-way 3in. duct in Portland-street. The conduits are laid in a trench 3ft. 4in. wide and 9ft. 6in. deep. A bed of coarse concrete 4in. thick was laid at the bottom of the trench, this being topped by a covering of fine sand concrete. The conduits were arranged in 10

Digitized by Google

layers of six ways per layer. They were accurately spaced by means of comb-shaped wooden templets, placed at intervals along the trench, the space allowed between each way being 1½in. The space between the ways was filled by the fine sand concrete, and about 1in. of this concrete was used between the respective layers. The conduit consists of tubes about 5ft. long, the ends of

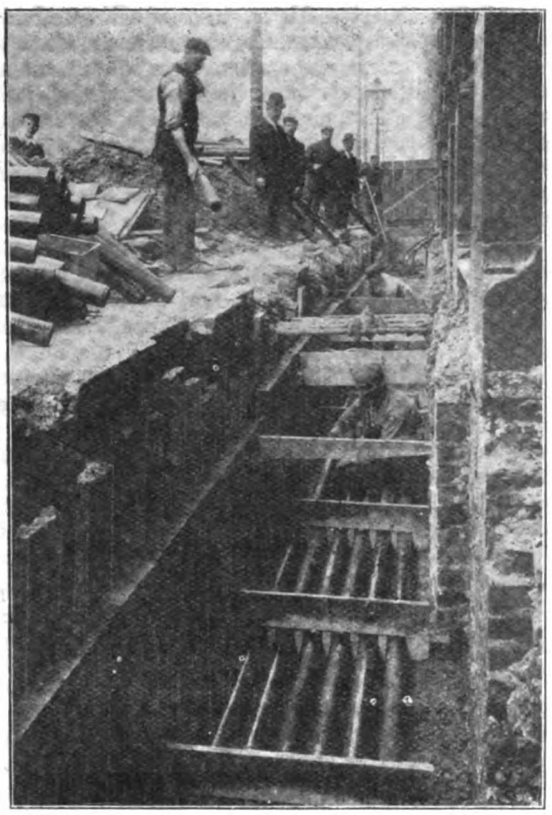

FIG 5.—Laying Fibre Conduits in Portland Street, Manchester.

each tube being tooled to make accurate socket and spigot joints; by this means perfect alignment and an absolutely watertight joint are secured. As a further precaution each joint is bound round with a piece of sticky tape, about 1½in. wide. That no time has been lost in executing this work, and that the public are consequently put to the minimum of inconvenience, is evident from the following figures: at 6.30 a.m. on Saturday, May 6, the work of opening 65 yards of street was commenced, and by 9 a.m. the following Monday morning the whole work was completed, including the filling-in of the trench, and this without any night work. The actual laying of the conduits was commenced at 6.30 on Sunday morning and by 8 30 on Sunday evening the whole of the 65 yards of 60-way duct was completed. In this section 130 tons of concrete were used and 3,900 yards of 3in. duct. This undoubtedly constitutes one of the most perfect examples of conduit work that has yet been carried out in this country, and it is interesting to note that the cost of the work is not greater than if a high-class earthenware conduit had been used.

The firm had also on view a new form of arc lamp from which exceptional results are claimed. It is an improvement on a type of lamp with which they have been experimenting for some time. In it two inclined carbons are used, together with a magnetic arrangement for blowing the arc downwards. The lamp uses pure carbon, and hence gives an intensely white light. With the example we saw at work the current was 11 amperes at 85 volts, and the firm claim to obtain no less than 3 c.p. for every watt expended. The fact that the craters are fully exposed accounts for this good result. The mechanism for controlling the inclined carbons has been perfected, and it is hoped shortly to put this lamp on the market, where it should find a great demand for street-lighting purposes.

Among the other interesting exhibits was a Reavell electrically-driven air process which was at work supplying air to a number of compressed-air tools. The Harris-Anderson system of patent feed purifiers was also exhibited, and experiments were being conducted as required to convince those present of the efficacy of the system. We described this method of feed-water purifying in connection with the new station at West Ham. It has been introduced, amongst other places, at the Glasgow Corporation tramway station, where it has given great satisfaction. The plant there is capable of dealing with 22,000 gallons of water per hour. A recent report from the city analyst concludes, after examination of samples of treated water, as follows: "(1) The analysis shows that there is no oil whatever of any kind present in the water; (2) the analysis shows practically the total absence of any scale-forming or crust-forming matter; (3) the analysis shows that the total alkalinity of the water is equivalent to 2·22 grains of carbonate of soda per gallon, which is exceedingly small, and the presence of which is desirable rather than otherwise; (4) the analysis shows that this water is eminently suitable for boiler feed purposes, and in that respect could hardly be surpassed.

The Delafon Syndicate, Limited, had on exhibition a number of primary batteries, which the Key Engineering Company are agents for in this country. These include forms which are much like those which have become standard articles, but we are informed that the Delafon Company have perfected the construction and used such materials as to get results which are remarkable. For instance, a large demand has arisen for the use of dry cells for the sparking coils on motorcars. The Delafon dry cell is specially adapted for this purpose in consequence of its low internal resistance. The curves which we give herewith are from results taken by an expert at the Manchester School of Technology on this type of battery, which is represented by curve R. The curves M and N are for cells of well-known make, which are looked upon as the best in the market. The reason for testing two of these was that

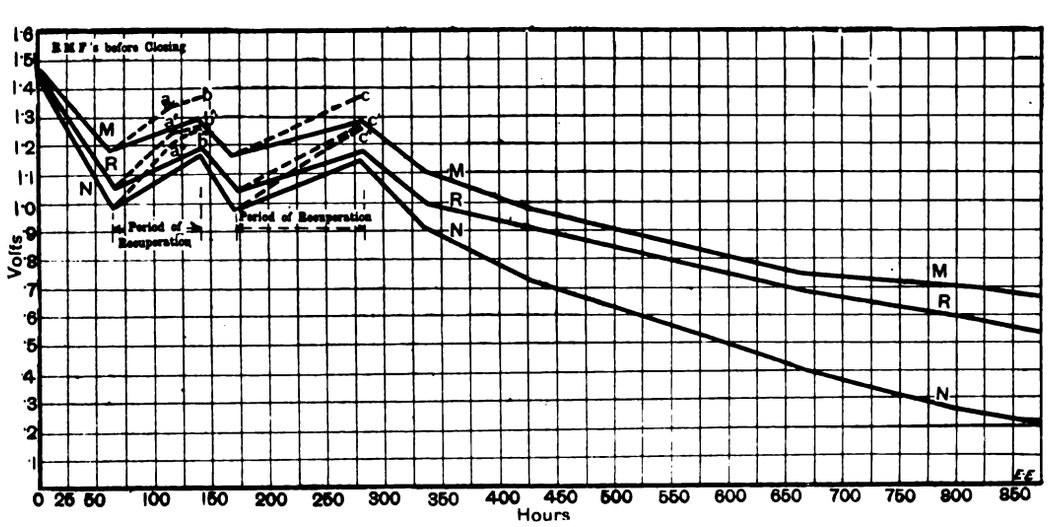

FIG. 6.—Life Test of Delafon Battery (R) against two of another make. The dotted portions of the curves show period of recuperation and E.M.F. on open circuit. The cells were all discharged through resistances of 5 ohms.

Digitized by Google

a cell could not be obtained of the same total weight as the one marked R of the Delafon Syndicate. The two batteries M and N were, therefore, selected so that their mean weight was the same as that of R. The actual weights were as follows: M, 9lb. 12oz.; R, 7lb. 1oz; N, 5lb. 4oz. The over-all dimensions were respectively: M, $4\frac{1}{16}$in. by $4\frac{1}{16}$in. by $8\frac{1}{8}$in; R, 7 6in. by 4 92in. by 3·74in.; N, $3\frac{5}{16}$in. by $3\frac{3}{16}$in. by $7\frac{3}{8}$in. The data considered were: (1) the E M.F of each cell on open circuit; (2) the internal resistance; (3) the behaviour of cell when delivering current; (4) the life test when working on a constant circuit; (5) internal condition of elements after the life test. The E M.F.'s of the three cells before the circuits were closed were respectively: M, 1·55; R, 1·53; N, 1·54. On momentary short-circuit the cells gave respectively: M, 13 amperes; R, 19 amperes; N, 10 amperes. Thus the short-circuit current of the Delafon cell is 50 per cent. greater than that of M, and nearly 100 per cent. greater than that of N. This shows that its internal resistance is lower, and that it is able to give a larger current in consequence. The measurement of the internal resistance of the three cells gave respectively: for M, 0·01 ohm; R, 0 05 ohm; N, 0 12 ohm.

The life tests were then commenced, and the curves reproduced herewith obtained. At the end of 65 hours the voltages were found to be: M, 1·12; R, 1 04; N, 0 98. The cells then had a week-end's rest. After another 30 hours' discharge they were again allowed to recuperate until 280 hours had elapsed from the commencement of the test, and they were then continuously discharged (excepting the very small intervals needed to open the circuits to determine the internal resistances), till cell R had reached a potential difference of 0 5 volt. On the above assumptions as to the life limits, the following useful life in hours was obtained for the three cells: M, 1,050; R, 780; N, 420. The useful life in hours per pound weight gives a more accurate comparison, and on this basis M will last 107 hours for each pound, R 112, and N 80. This shows that the Delafon cell lettered R was superior to either of the other two. Some other trials are now proceeding with these cells for motorcar work, and results which were shown lead us to conclude that they will be exceedingly useful in this field. They have the advantage that they do not suddenly cease to give a sparking current, as is the case with accumulators if discharged too far.

## ENGLISH-MADE EDISON LAMPS.

At the time of our visit last week to the British-Thomson Houston Company's Rugby works to see the Curtis turbine, we had also an opportunity of inspecting the modern lamp works in full swing. The making of incandescent lamps has always been associated hitherto with experts in glass-blowing. We were, therefore, surprised to find that in a factory turning out lamps to the extent of 30,000 a week there was only one glass-blower employed. All the rest of the many operations involving glass work were performed by automatic machines fed by girls. These machines were designed for a great variety of purposes, but in general principle they were not unlike. They consisted, as a rule, of a revolving frame with a number of clips in which the lamps in various stages of manufacture could be held. The girl who placed lamps into these clips moved the frame round by one step each time. This brought the lamp successively opposite one or more blow-pipe flames, which automatically performed the operation required. The girl had then only to remove the bulb which had been advanced one stage in manufacture and replace it by another to be operated upon. In this way the bulbs received into the factory passed through a variety of processes. For instance, they first have a small hole made at the upper end. The next step is to fix to the edges of this hole a small glass tube through which the lamp is exhausted. The larger tube at the other end is then prepared to receive the mounted filament, which has already gone through a number of stages of manufacture. The filament is introduced into the lamp, sealed in, and the lamp passes on to the exhausting benches in a very short space of time. These glass-blowing machines are the outcome of years of experimental work, and it would be unfair to the company to describe them in detail. It suffices to say that they allow of comparatively unskilled labour carrying out excellent work in a minimum of time.

The removal of the air from the lamps is done entirely by mechanical pumps. The first part of the exhaustion process is effected by one pump while the lamps are cold. After a certain stage the operation is continued by a second pump, which creates a better vacuum. At the same time current is switched on to the filament, which renders it incandescent. Before the process is commenced, a small quantity of a certain chemical is introduced into the tube through which the lamp is exhausted. This tube is now heated by a blow-pipe, and the substance gives off a gas which combines readily with the remaining traces of air within the lamp. The operator is able to judge by the colour of the light given off by the filament when the vacuum is satisfactory, and she then seals off the tip of lamp. The process of mechanical exhaustion with this final aid in removing the last traces of air is much more rapid than with mercury pumps. We need hardly say that it is also much more healthy for the operators.

As regards the grading of the lamps, the carbon filaments are all flashed to a uniform thickness before they are mounted. Slight variation in the voltage required is then met by varying the length of the filament. The practice adopted by the company is to cut the filaments to practically the right length for a medium voltage, and then to accurately grade the lamps after completion. This is done on the photometer. The voltage applied to the lamp under test is varied until it gives the required candle-power. The girl who feeds the testing lamp-holder socket of the photometer bench reads off this voltage on a scale, the indication of which is automatically given by the operator when adjusting the same to get the correct candle-power. This voltage is marked on the lamp, which is then put with others from the same batch needing equal voltage to give the rated candle-power. Thus, out of one series of lamps, the variation may be from, say, 210 volts up to 230 volts by steps of five volts. The grading ensures that the nominal candle-power will be obtained when the lamp is connected to a circuit of the voltage marked on the glass. Both the standard lamp and the lamp under test are made to revolve while being tried, so as to avoid any error due to the angular positions of the filaments with respect to each other.

The details for testing the lamps for mechanical strength in those parts most likely to be injured were most interesting, and we saw quite a number of lamps being discarded which otherwise would have vexed consumers by their short life. It is in the repairs to these defective lamps that the single glass-blower is employed. The net result of the introduction of so many automatic processes is that a large number of high-class lamps which are well graded as to voltage and candle-power can be turned out in a comparatively small factory four storeys in height.

At present the ground floor is used for other work, but the increase in the demand for lamps will shortly necessitate the moving of this to another building.

## LONDON ELECTRIC POWER BILLS.

Lord Camperdown's Committee to-day threw out the Charing Cross and Strand and City of London Electric Power Bill. They passed the North Metropolitan Bill, and in the Central London case, whilst declining to extend the area of supply, allowed the other parts of the Bill to proceed. They refused to sanction the clauses relating to the linking up of the generating stations and the extension of area in the County of London case, but otherwise allowed the Bill to proceed. With regard to the far-reaching proposals of the Administrative County of London Company, they asked that the opponents and promoters should meet with a view to submitting suggestions for the purpose of obviating any hardships which the passing of the Bill might inflict on other companies.

## LIGHTNING.

The report of the Lightning Research Committee organised by the Royal Institute of British Architects and the Surveyors' Institute is a most valuable one from several points of view. The preface to the report written by Sir Oliver Lodge, F.R.S., gives a concise and lucid explanation of the two types of discharge which are liable to cause damage to buildings. As Sir Oliver Lodge was the first to insist upon the oscillatory character of certain lightning discharges causing them to be the most destructive, his preface is a good introduction to the records which are given in the report, and which prove his theory most conclusively. These records, which are selected from a large number in the possession of the committee, are published in a form which is to be commended. The routine adopted by the committee is to issue to their expert observer in a given district schedules on which to fill in information as to buildings struck by lightning in the district. On these forms twelve different points are given on which information is desired to enable conclusions to be drawn as to the efficacy or otherwise of the protection afforded by the system of lightning conductors in the buildings struck. The analyses of a number of these selected reports show that, even when a reasonably good earth connection is provided, the discharge frequently leaves the conductor and travels through a high resistance path in order to reach metal work in the building which affords an alternative path to earth. Even the connection of this metal work to the conductor is not always sufficient to prevent damage, and it is necessary to have in large buildings a number of conductors which are interconnected one with the other, and also connected at several points to any large system of metal work in the buildings. An example of this was the St. Pancras Church at Euston, which has a lead roof. The lightning conductor from the tower was connected with one end of this roof. From the damage done by a lightning stroke it was evident that violent electrical oscillations were set up in this lead roof, which ultimately found their way into the hot-water radiator system, and thence into the gas-pipes, which were broken The conclusion was in this case that if an additional lightning conductor had been connected with the other end of the lead roof and the heating system had been connected to earth, no damage would have been done. Other instances from the report clearly emphasise the danger of leaving lead flats or ornamental ironwork unconnected to earth. With the evidence obtained from these reports the committee have been able to suggest amendments to the rules for the erection of lightning conductors which were issued by the Lightning Rod Conference of 1882. The chief points on which modifications should be made may be briefly referred to. The provision of a non-oxidisable point for lightning conductors is no longer insisted upon. Two lightning conductors, one on each side of a factory chimney, are recommended instead of one conductor connected to a ring at the top of the chimney. The use of iron is preferred to that of copper, as its higher resistance, and especially its higher inductance, tend to reduce the surging of current. The use of cinders or coke as a conducting medium round the earth-plate is not advised, owing to possible electrolytic action. Charcoal, or pulverised carbon, is preferred, and may be used in connection with a tubular earth connection consisting of a perforated steel spike driven into moist ground. This earth connection can be kept moist by being connected to the rain-water pipes. Above all, stress is laid on the efficient connection to earth of all metal work within the buildings to be protected. It is interest-

Digitized by Google

ing here to consider the problem which has to be solved by the power distribution engineer — *i.e.*, the efficient protection of a large system of metallic conductors, which cannot be directly connected to earth without destroying the object for which they have been erected. A lightning discharge from such a system to earth is the more objectionable, because, as a rule, the currents from the generators would continue to travel along the path of the discharge, which would be rendered more or less conductive. The different types of lightning arresters and systems for the protection of such plants are numerous, and their efficacy is unfortunately dependent to a considerable extent on the character of the lightning discharge. They may frequently do all that is needed for most lightning discharges, and then fail under specially severe circumstances. We believe, however, that all the ingenuity expended on the subject has not succeeded in producing a better system of protection than that of a high-resistance leakage path to earth. With high-voltage installations this is frequently provided by a jet of water passing between the conductors and earth. This device prevents by leakage the accumulation of a high static pressure in the metallic system, and hence tends to prevent the condenser type of lightning discharge, which is the most dangerous. The loss of power in this leakage path may be considerable at extra high voltages, but it is more than counterbalanced by the security afforded against breakdown. It would be well if information as to the working in practice of these various systems of lightning protectors could be regularly collected and analysed by a committee of electrical engineers, proceeding on the same lines as the committee above referred to.

## CORRESPONDENCE.

### ERRATUM.

SIR,—In my answer to No. 776 in last week's issue an obvious oversight led to an error in the value of R, which should read

$$\frac{150 + 175 + 150}{2} + 100 = 338 \text{ approx.}$$

This alters the value of $n$ to 20 approx.—Yours, etc.,

A. F.

## FORTHCOMING EVENTS.

SATURDAY, MAY 20.

**Rugby Engineering Society.**—Visit to the Lots-road power station at Chelsea.

MONDAY, MAY 22.

**Society of Arts.**—At 8 p.m., "The Uses of Electricity in Mines," by Mr. H. W. Ravenshaw. Cantor Lecture (II.).

TUESDAY, MAY 23.

**Society of Arts.**—At 8 p.m., "The Cape-to-Cairo Railway," by Sir C. H. T. Metcalfe.

WEDNESDAY, MAY 24.

**Society of Arts.**—At 8 p.m., "Modern Lightning Conductors," by Mr. Killingworth Hedges.

**Institution of Electrical Engineers (Students' Section).**—At 7.30 p.m., annual general meeting, followed by a paper "On E.M.F. Wave Forms," by Messrs. J. B. Sparks and A. Biederman.

THURSDAY, MAY 25.

**Institution of Electrical Engineers.**—At 8 p.m., "Wireless Telegraphy Measurements," by Messrs. W. Duddell and J. E Taylor.

**Royal Institution.**—At 5 p.m., "Electromagnetic Waves," by Prof. J. A. Fleming. Tyndall Lectures (I.).

FRIDAY, MAY 26.

**Institution of Electrical Engineers.**—At 5 p.m., annual general meeting.

**Physical Society.**—At 3.30 p.m. (National Physical Laboratory, Bushy House) the following demonstrations will be given: (1) "The Specific Heat of Iron at High Temperatures," by Dr. Harker; (2) "The Measurement of Small Inductances," by Mr. Campbell; and (3) "Two New Optical Benches," by Mr. Selby.

## LOCAL SECTIONS: A SUGGESTION.

BY B. C. H. J.

Apart from the parent community in London there are now six local sections of the Institution of Electrical Engineers in the British Isles, and two in our Colonies, having a total of about 2,000 members of all grades. It may be of interest to note that the exact figures of the *British* sections' memberships are as follows: Manchester, 758; Leeds, 225; Glasgow, 214; Birmingham, 214; Newcastle, 200; Dublin, 74. The members of these provincial and Colonial sections nominally enjoy all the benefits of full membership, and so far as hearing papers read and discussed, and partaking in the conversational free feed afterwards, this is a fact, for such papers and discussions are acknowledged to be at least as useful as those provided at the London meetings.

There is one item, however, in which local sections are at a disadvantage, and that is the difficulty of access to technical periodicals and books. The London member who desires to consult the electrical journals from any part of the world can see them at the headquarters in Victoria-street, not to mention the piles of technical periodicals on view at the British Museum and the Patent Office libraries. The very complete collections of technical works at each of these three institutions are also freely open to his inspection. The provincial member, even in a town possessing a local section, is cut off from these advantages, and must have recourse to the local public library, which usually has a meagre selection of technical periodicals and books, more remarkable for being dirty than up-to-date. The members residing in the numerous towns without local sections are even worse off, by the entire lack of papers and discussions, with coffee and "shop" dessert. Further, they have less chance of using the electrical literature in their public libraries, for a simple and sufficiently obvious reason to those who know the class of reading matter provided in public libraries in most towns.

This dragging in of public library facilities is, however, a little beside the mark. The writer wishes to suggest that every local section should have local headquarters of some description, if only a single room, which should be of use primarily as a reference library. Such a library should contain all the electrical and some of the principal engineering periodicals of Great Britain, together with the more important ones of other countries. It should also have a selection of standard electrical books. As regards those other technical works which may be required for reference, but which are too specialistic in character to be obtained at such a local section library, would it be too much to suggest that the ordinary facilities of Mudie's be followed, and that it should be possible for a provincial member to obtain such books from the Institution library by mail, on payment of the necessary postage. Such an arrangement would be of very considerable value to the more studious portion of provincial members.

The writer would further suggest that towns not possessing local sections, but with a certain minimum number of members (of which there are some very big examples, such as Liverpool and Bristol), might be allowed a room and attendant for a certain number of evenings a week, depending on the number of members domiciled there; in which establishment the bill-of-fare would consist of fewer standard books and current electrical literature, while the arrangement of borrowing books from headquarters would hold good as for local sections.

Now, these suggestions may be looked upon with scorn by London members, and one can imagine them saying: "Let the provincial devils wallow in their disadvantages; what are they to ask for privileges similar to those which we ourselves enjoy!" And possibly others may look more charitably upon the matter, and will wonder how much money the Institution would drop down the grid if such an arrangement came into effect. This view, however, would be almost as short-sighted as the scorn of the thoughtless is selfish. Apart from the justice of such an arrangement, the welfare of the Institution would be served by the large increase of membership that would ensue.

At present, beyond the more or less empty honour of the membership initials on a man's business card, and the

Digitized by Google

privilege of receiving *Proceedings* dealing with papers read three or four months back (of which full details have generally been published in the electrical periodicals of the long-ago), there is little advantage to a provincial member in his membership. Anyone can participate in the local section meetings, and gather therefrom what crumbs of wisdom are on tap. Consequently there is not the rush there might be to obtain the "degree" of membership, and especially outside of the local section districts. With the advantages suggested, not only would the handicap upon provincial members be lessened, but a large accession of new members would ensue, whose fees would cover the cost of the more expensive arrangement. And in those towns where the membership was hardly up to the strength necessary to allow of a local centre being provided, it may be imagined that the existing members would endeavour to enlist their brethren outside the fold, in order to total the required number of local members.

The arrangement should benefit everybody concerned, and would probably be the means of initiating valuable combinations of technical societies. In Manchester, for instance, there are half a dozen fairly influential engineering organisations, each separately and more or less temporarily housed, who would find it advantageous to become joint possessors of a permanent home, in which to pool their libraries, periodicals, and other possessions for common benefit. This latter scheme has been in the air for some time, but no definite shape has yet been taken. In other towns something similar would doubtless happen, if Manchester, true to axiom, "thinks it to-day."

These suggestions are made in the interests of numbers of members who would welcome the inauguration of such local libraries as a means of reference in time of need, and to enable them to keep in touch with current events. It is hoped that his idea will not be put up as an Aunt Sally to be knocked down, but rather as a target which will be used as a base for sticking valuable points into.

## INSTITUTION OF ELECTRICAL ENGINEERS.

### Students' Visit to Leeds.

(*Concluded from page 668.*)

On Wednesday afternoon the generating station of the

YORKSHIRE POWER COMPANY

at Thornhill was visited. The Curtis turbine has been adopted as the prime mover, one unit of 1,500 kw. being already installed, while another set is expected to be running in a month's time. The boiler-house calls for no special comment, and the switchboard is equipped upon the well-known B.T.H. remote-control system. The lightning arresters are interesting. The line is brought to the first of a series of five small brass cylinders separated from one another by short gaps, the last cylinder being connected to about an 8in. length of 10mm. carbon; two more lengths of carbon follow, and then another series of five brass cylinders as before, the ends of all the arresters for the separate phases and feeders being connected to the common earth-wire. The theory of the arrester is that when a discharge takes place the fumes given off from the brass, besides being in themselves badly conducting, are cooled by the proximity of a comparatively large amount of metal, so that the arc cannot be maintained. Steel chimneys have been adopted built up of 30 rings each 5ft. high, with an iron ladder outside the stack running right to the top.

MESSRS. JOHN FOWLER AND CO.'S WORKS.

were first on the programme on Thursday. This firm build steam-engines for all purposes, making a speciality of heavy traction engines. They have also a completely equipped electrical department. The shops are all electrically-driven, and for this purpose two 300 kw. 200-volt direct-current sets have been installed in the power-house. This company are one of the few in England which has adopted a cast-steel yoke for their multipolar machines. The appearance at first is rather striking, as less than half the section is required compared with the usual cast-iron yoke. Automatic turret lathes have been adopted very largely in these shops. As a continual supply of oil floods the work, a necessary accessory where these machines are used is an oil separator. This consists of a conical pan into which the turnings are shovelled, and which is then revolved at a high speed so that the oil, by centrifugal action, is brought to the widest part of the cone and thrown out into an outside vessel through a slit, so fine that the finest needle will not pass through. Other interesting machines seen in action were a vertical boring mill used for shaping out oval plates by giving a reciprocating motion to the tool, a machine for grinding valve links to any curvature by rocking the table holding the work about an adjustable centre, and a machine for forging boltheads, square or hexagonal, from the round bar.

In the afternoon the works of

MESSRS. GRAHAM, MORTON, AND CO.

were visited. As is well known, this firm make conveying and elevating plants and constructional steelwork of all kinds. In 1903 they erected their present works at Hunslet in the short space of 5½ months, and appear to have been on the hustle ever since. Every labour and time-saving device has been adopted, from a blue-printing equipment which turns out two double-elephant prints, dried and trimmed, in three minutes, to a messenger-boy system in the shops, by which a workman, pressing a button on the nearest standard, calls up a boy who fetches him tools, etc., thus saving the workman the trouble of leaving his work to fetch them himself. With regard to the work of this firm, one type of chain used on their bucket conveyors may be noted. Alternate link pieces consist of a steel drop-forging and a piece of punched steel plate. The forging is made with a projecting flange where the linking pin passes through, and this forms a bearing for the adjoining link of steel plate. In this way all strain is taken off the link-pin, whose function is simply to hold the links together. Another interesting operation is the making of steel colliery trucks in one piece from the sheet. First, the four sides are bent up, leaving, of course, projections at each corner. Next, one pair of opposite sides are corrugated, and, finally, the corner flaps are bent round flush with the other sides, thus giving double strength at the corners.

On Friday morning the party visited the works of

THE FARNLEY IRON COMPANY, LIMITED.

This firm, by taking every care and adopting superior methods of manufacture, turn out a "Best Yorkshire iron" which, although somewhat dearer than the ordinary makes of iron, is preferred by the leading railways and colliery companies for such parts as coupling shackles, which have to withstand sudden shocks. The works stand on the side of a hill, and the ore and coal are delivered from the neighbouring mine at the top, and pass through the various processes on its way down the hill, as it were. Like all the other firms visited, electric driving has been adopted. At first, owing to the heavy nature of the work in most of the machines, the electric drive was not entirely successful, but by substituting belt drives for direct gearing perfect satisfaction is now obtained. The first process is that of "calcining" the ore with coke, which drives off moisture and partially reduces the ore to a lower oxide. After this it is transferred to a blast furnace, the charge also consisting of limestone and coke, of which the following quantities go to produce a ton of iron: 45cwt. of calcined ironstone, 12cwt. of limestone, and 28½cwt. of coke. It is the usual practice to heat the blast from the escaping gases, but at Farnley a cold blast is used, this, it is claimed, tending towards a better quality of iron. The next process after the running of the iron into pigs from the blast furnace is to remove the carbon (about 3 per cent.) in the puddling furnace. Here again the Farnley Company depart from the usual practice, and interpose an intermediate operation—viz, of refining the pig to rid it of small quantities of impurities, chiefly sulphur. In the puddling furnace the refined pig is subjected to a reducing atmosphere, and the carbon goes off as oxide, leaving the pure iron a pasty mass, which is removed and pressed under the steam hammer, when the dross and unburnt fuel squeezes out. The wrought iron is then cut up and piled for heating in a second furnace, after which the piles are hammered into one mass. It is then ready

Digitized by Google

for reheating preparatory to being rolled to the section required. After rolling, a circular saw running at the speed of the ordinary wood saw cut the iron in lengths while it is still red hot. The main difference between steel and iron is seen in the character of the fracture when samples are broken in the testing machine. With steel the fracture shows a crystalline structure, while with iron a fibrous structure is observed. This is due to the steel being in the beginning a cast ingot, which afterwards rolled or forged to the desired dimensions, while iron is prepared by hammering and piling, so that it is claimed a much more uniform material is obtained. It is also said that iron is less susceptible than steel to "fatigue" produced by continued alternations of stress.

In the afternoon the party went over to Bradford and visited the works of the

PHŒNIX DYNAMO MANUFACTURING COMPANY.

This firm has a well-equipped factory for the manufacture of continuous and alternating current machinery, especially of small continuous-current enclosed and semi-enclosed motors for workshop driving. It claims that in 1895 it was the first in the North of England to manufacture an enclosed type of motor. Recognising that the

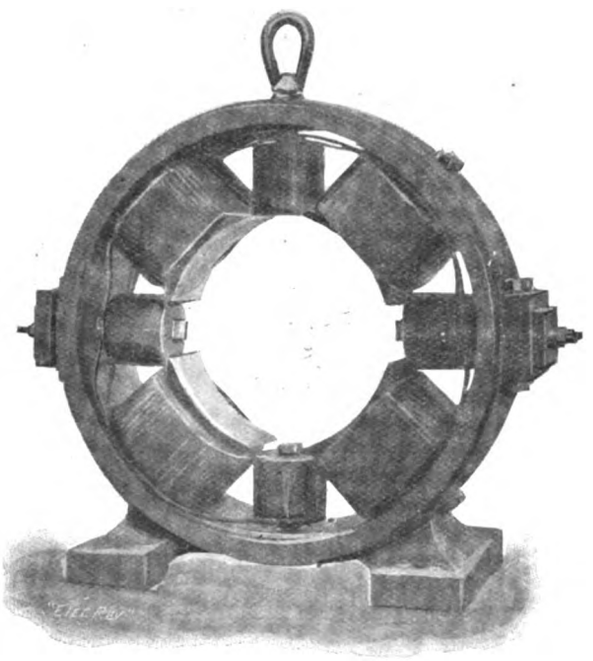

FIG. 1.—Four-Pole Phœnix Dynamo with Intermediate Commutating Poles.

limit of output of a continuous-current machine is controlled simply by the sparking and the heating, they have so perfected their designs in these directions that for the same power a much smaller, and, therefore, cheaper, machine can be built. In the first place, they have designed a special form of commutating pole, with a decreasing breadth in the direction of running when the machine is acting as a dynamo. The party were fortunate in seeing two of these machines of 50 kw. capacity coupled up for Hopkinson's test. With overloads of 50 per cent. they ran without any signs of sparking, and also stood temporary overloads of 100 per cent. To show the effect of the commutating poles, their windings were then short-circuited, and under these circumstances the machine would not stand an overload of 20 per cent. With regard to the heating limit, every arrangement for ventilation both in armature and field coils is provided. In the former, air ducts are provided even in the smallest armatures and the end windings are so designed that there is a space for air circulation between each coil. In field coils a special pattern with air passages right through the windings is used, the coil consisting actually of two concentric coils separately wound. With such a construction it is claimed that the temperature rise is halved for the same amount of energy lost in the coil. For the smaller motors the firm use laminated poles, and by riveting tightly it is found practicable to bolt them direct on to the magnet frame. For larger machines a solid pole is used with laminated pole-shoes. In induction motors only the smallest have squirrel-cage rotors, and in these slots are milled in the brass end plates, and the rotor conductors are sweated in direct. The firm also make a handy form of bench drill for sizes up to ½in. It is driven by a ½-h.p. motor, the motion being conveyed to the drill through a friction gearing, thus giving a ready means of changing speed for the different sizes of drill.

Later in the afternoon the party went over the extensively equipped repair shops of the Bradford Corporation tramways. In the evening the students met together at dinner at the Hotel Metropole, after which a pleasant time was spent in exchanging experiences and reminiscences more or less of an electrical character.

On Saturday morning a very successful and enjoyable week's excursion was brought to a conclusion by visits to the

LEEDS LIGHTING AND TRAMWAY POWER STATIONS.

As these have been dealt with at length in back volumes of the *Electrical Engineer*, it suffices only to mention that the Leeds supply, first started as a single-phase supply at a frequency of 83, is being gradually converted to a 50-frequency two phase system for the benefit of the motor load.

In conclusion, the writer wishes, as a student for the students, to express their appreciation and thanks to the

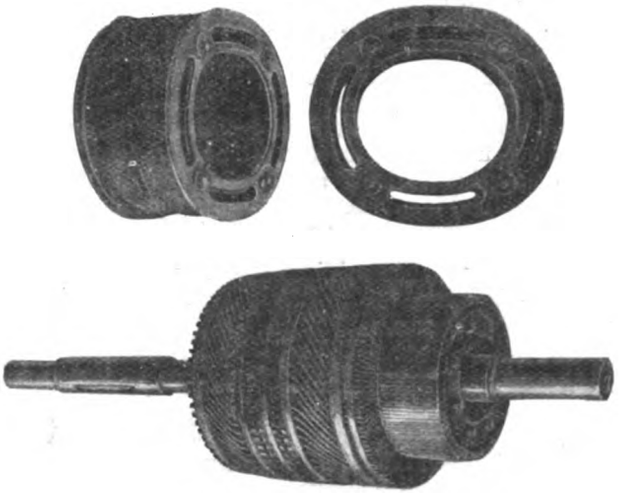

FIG. 2.—Armature and Ventilated Field Coil of Phœnix Dynamo.

proprietors of works for the cordiality with which they were received on every occasion.

## ELECTRICITY AND FIRE INSURANCE.

BY A. H. MAYES.

The unfair and inconsistent attitude adopted by many fire insurance companies with regard to premises wherein electric power for lighting and motive purposes is used, is of such wide importance that a little plain speaking will be entirely justified. In the first place, it appears that the powers that guide the helm of the insurance companies have by some mental process, which it is beyond the power of a practical and impartial person to understand, arrived at the conclusion that a supply of electricity on a premises is a source of considerable fire risk, greater, in fact, than had gas or some other agent been employed. Now, looking at the matter honestly and with a perfectly unbiased mind, one is compelled to say at once that such a contention is absolutely unjustified, opposed to common sense, and totally unsupported by the result of experience.

Even allowing that every fire attributed to electrical causes is rightly classified, it cannot be denied that electricity still stands forth as by far a safer agent than gas. It is, however, quite certain that a little more attention to detail in carrying out installations would still further reduce the possibility of fires from electrical causes, and the writer proposes to say a few words upon this from a practical standpoint. How often one sees the cause of fire vaguely attributed to "the fusing of an electric wire."

Digitized by Google

Now, either the fire was not caused in this manner at all, or else the wire in question must have been installed under conditions sufficiently extraordinary to take one's breath away. The smallest conductor ever used, or which is supposed to be used for installation purposes, is No. 18 S W.G., and as the fusing current of No. 18 S.W.G. copper wire is 108 amperes, one is led to ask what sort of branch fuse was in circuit with that unfortunate wire. The alternative conclusion is that there was *no fuse at all*, and, further than that, one is confronted by the appalling question of how such an enormous current could have found its path, even then, through the wire in question. If due to earthing of the wire, the earth must, indeed, have been of an efficient character, and if due to a "short-circuit" the point of contact must have had a strangely low ohmic resistance. Even then we are not out of our troubles, for we have yet to explain how the service company's fuses managed to stand against this great extra demand upon their energies. It will, of course, be evident that the danger point would be reached with a current less than that required to absolutely fuse the wire, but after making all allowances the point requires a large amount of explanation.

Another and more probable source of danger is in installing incandescent lamps in such a manner that the heated bulbs can come into contact with articles of an inflammable character. It is a common practice when installing lamps for lighting a draper's window to attach the lamp to a considerable length of duplex flexible conductor, in order that the light may be hung in any desired position, and thus it is that one frequently sees goods of a highly inflammable character in actual contact with the bulbs. Such a practice as this should be absolutely prohibited, and a rule should be strictly enforced that all lamps used under such conditions be enclosed in a wire net guard or other effective safeguard. The overheating of resistances used in connection with arc lamps is undoubtedly a source of danger, but at the same time one which might be rendered practically nil by proper precautions in the matter of carrying capacity and fixing.

Coming to the question of electricity as used for power work, we are at once confronted by an element of danger in the form of resistances as used for starting and speed-regulating purposes. Here again, however, proper precautions would reduce the fire risk to practically nil, but, unfortunately, great carelessness is often displayed in the method of fixing and protecting these pieces of apparatus. A short time since the writer was inspecting a large motor installation in London, and found gross carelessness displayed in the above matter. A 25-h.p. starting resistance of the wire coil type had been arranged to stand upon the cement floor in the basement, and as the sheet-iron case containing the coils was open at the bottom, a quantity of waste paper and rubbish had gradually worked its way underneath, and actually found its resting place amongst the coils. The above apparatus should certainly have been fixed about a foot from the ground, and have been provided with a perforated iron bottom.

In several other instances it was found that starting resistances were quite unequal to the demands made upon them, having insufficient carrying capacity, and often attaining a red heat in operation. More care was, therefore, essential in selecting a starting resistance suitable for the particular work to be performed. It may be added that the switch and resistance should always be enclosed in an outer case of strong sheet steel, which is an adjunct of a very necessary character on account of the fact that a considerable amount of sparking takes place upon the switch contacts, and particles of molten metal are at times thrown off. Main switches should most certainly be enclosed in cast-iron cases, as they are frequently liable to rough handling, and it often happens that an arc is set up owing to defective action.

Another important adjunct to power installations is the fuse, and unless a proper type be employed they are undoubtedly a source of fire risk. Whether the open or enclosed type of fuse be selected, there are two points of the greatest importance to be observed—that is, that the terminals shall be an ample distance apart, and the device shall be enclosed in a cast-iron case.

If proper attention were paid to the above simple points the fire risk would be still further reduced, and would bring still nearer the day when fire insurance companies will be compelled to admit that electricity is by far the safest agent to employ for both lighting and power.

## TRADE NOTICES AND NOVELTIES.

### Idle-Current Ammeter.

One of the requirements of modern central-station practice is an instrument which will indicate the idle or wattless current

FIG. 1.—Idle-Current Ammeter.

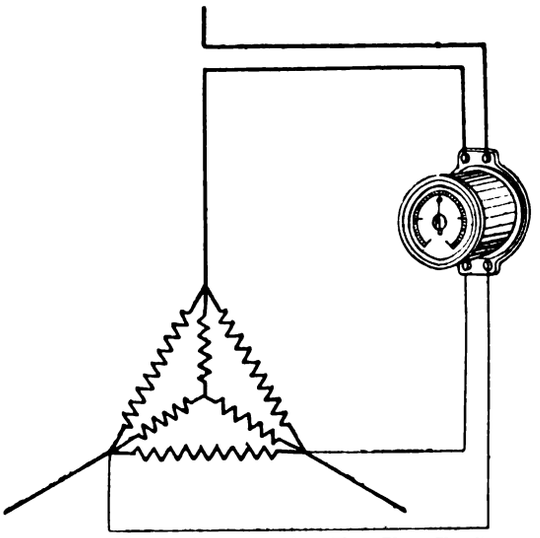

FIG. 2.—Connections for a Three-Phase Circuit.

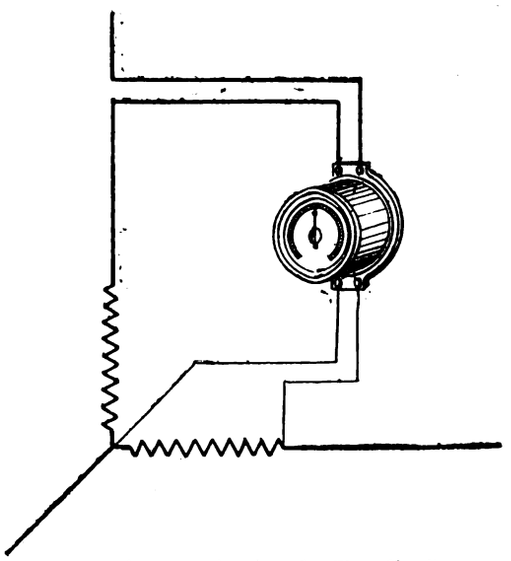

FIG. 3.—Connections for a Two-Phase Circuit.

in any circuit. The knowledge of this quantity enables the most economical regulation to be made, the presence of cross

Digitized by Google

currents is at once shown, and the minimum idle current in the circuit obtained. In order to meet this demand the instrument illustrated in Fig. 1 herewith has been put on the market by Messrs. Ferranti Limited, Hollinwood, Lancs. It measures V C sin $a$, where V = virtual volts between phases, C = virtual current in one phase, and $a$ is the angle of lag. At any particular normal voltage, therefore, it can be calibrated in terms of C sin $a$, or, which is the same thing, in terms of the *idle current* in the circuit. By means of this instrument the switchboard attendant is enabled to regulate the excitation of the machines to minimum idle current, which is the condition of most economical working. Power factor indicators have sometimes been used for this purpose. The great disadvantage of these indicators is that as they only measure a ratio, there is no controlling force on the moving part. This latter simply takes up a position where the two magnetic forces acting on it equalise one another. The idle-current ammeter has a strong controlling spring like an ordinary ammeter; its indications are therefore very definite, and can be relied upon. The accompanying diagram (Fig. 2) shows how the instrument should be connected up in a three-phase circuit, while Fig. 3 shows the arrangement for a two-phase circuit.

## Catalogues, etc, Received.

TELEPHONES.—The Berliner Telephone Manufacturing Company, 200, Upper Thames-street, London, E.C., have issued a supplement to the fifth edition of their catalogue, containing reduced prices.

ANTI-FRICTION METAL.—The advantages of Glacier anti-friction metal are dealt with in a pamphlet just issued by the Glacier Anti-Friction Metal Company, Limited, 91, Queen Victoria-street, London, E.C. Results of tests and copies of some valuable testimonials from users are included.

MAXIM LAMPS.—The Sir Hiram Maxim Electrical Company, Limited, Maxim Works, Gillingham-street, Victoria, London, S.W., inform us that they have taken over the entire manufacture of the "Maxim" arc and incandescent lamps. The firm's 1905 catalogue, a copy of which is to hand, illustrates the different patterns of these lamps supplied by them, besides a variety of accessory apparatus.

FEEDER PILLARS.—Sheet No. 119 just issued by Messrs. Ernest F. Moy, Limited, Greenland-place, Camden Town, London, N.W., illustrates a lighting pillar for a three-wire network with 440 volts across the outers. It is fitted with disconnecting links on the three feeders, and 200-ampere 6in. clear break switch fuses on the outers of the four distributors. The middle wire is mounted on a separate panel at the bottom. We note that the firm manufacture feeder pillars to suit any special requirements for traction or lighting systems.

SIEMENS'S PUBLICATIONS.—Two new publications are to hand from Messrs. Siemens Bros. and Co., Limited, York-mansions, York-street, Westminster, S.W. One of these—Leaflet 562—gives dimensions, weights, and gearing ratios of the firm's G. A. motors with geared countershaft. Particulars of the motors are included on Leaflet 560, already noticed in our columns, the outputs varying from 25 b.h.p. to 150 b.h.p.—depending on whether the motors are protected, ventilated-enclosed, or fully enclosed. The other—Specification 7 B—describes their new type 5 B and 5 B A machines—protected, ventilated-enclosed, and fully enclosed. These are small-sized and compactly designed bipolar machines. The outputs in the case of the motors vary from 1 b.h.p. to 3 b.h.p., and for the protected dynamos from 1·7 kw. to 2·6 kw.

## PERSONAL.

The Kingston-on-Thames Town Council have increased the salary of Mr. Edgcome, the electrical engineer, from £350 to £450 per annum.

Mr. W. G. Snell, tramway inspector, has been appointed traffic superintendent of the new Perth tramways system.

Mr. Robert Birkett, electrical engineer to the Burnley Corporation, has been appointed electrical engineer and general manager of the tramways at Southend-on-Sea.

## APPOINTMENTS VACANT.

**Assistant Engineer,** Middlesex County Asylum, Napsbury, St. Albans, Herts. Wages, 35s. weekly and house on the estate. Applications by May 20. See advertisement in last issue.

**General Manager,** Johannesburg, £2,000; Station Engineer, £1,000, with house. Applications to Mordey and Dawbarn, 82, Victoria-street, Westminster.

**Shift Engineer,** Manchester. Wages, £150. Applications by May 22.

**Tramways Manager,** Erith. Salary, £250 per annum. Applications by May 27. See advertisement.

**Chief Assistant Electrical Engineer,** Battersea Borough Council. Commencing salary, £200 per annum. Applications by noon on June 6. See advertisement.

## THE SUPPLY OF CHEAP ELECTRICAL ENERGY FOR INDUSTRIAL PURPOSES.*

BY J. A. JECKELL.

I propose for the sake of convenience to divide this paper into three headings—viz.: (1) a short history of the supply of electrical energy from central supply stations; (2) the advantages of a cheap supply; (3) the possibility of such a supply being given.

In order to rightly understand the present position, it is necessary to see how it arose. You will be aware that about the year 1890 a supply of electricity from central supply stations was beginning to be given. Electricity was used to meet the then pressing demand for a better light. Those of you who were in London about this time probably noticed the very large number of different systems of lighting by gas then in vogue, showing that many attempts were being made to obtain a really first-class light. Electric light, coming to the front at this time, supplied a long-felt want, and was rapidly taken up by a large number of persons who did not mind paying a comparatively high price for it. This is what we may term the *luxury demand*. At this time the supply of electricity was mostly in the hands of companies who, owing to the large price then obtained for electricity, and not because the cost of manufacture was low, were paying good dividends.

About this time the wave of municipal trading swept over the country, and seeing that Parliament considerably favoured (for reasons best known to themselves) the supply of electricity by local authorities, local authorities enticed by the large dividends paid by the companies went in for the business. Some because the supply of other commodities, such as gas and water, having been in the hands of private companies, local authorities thought they had not been well served and could do better if they undertook this new business themselves. Some because they considered that the supply of any commodity which carried with it the right to break up the streets should be in the hands of the highway authority. Others, again, because they owned the gasworks and did not desire competition. Others, again, promoted provisional orders with no intention of putting them in force. This supply of electricity, however, differed in one very essential point from the supply of gas or water, which were up to that time practically the only two forms of municipal trading. If a gasworks or a waterworks did not pay, the simple expedient of raising the price could be resorted to, as both undertakings were virtual monopolies. But electricity works would have to compete with the gasworks whether these were owned by a local authority or by a company. Therefore, in order to make electricity works pay, the methods which are used in commercial undertakings, which have to face competition, required to be adopted, and this was too often lost sight of. These are, as is well known: (1) the expenditure of the smallest amount of capital; (2) the production of the article at the lowest possible figure; (3) the selling of the largest possible amount of that article; (4) the payment of the manager, too, largely depend upon the financial result he obtained.

When local authorities decided to undertake the supply of electric energy, the only course open to them was to consult an expert. Unfortunately, from the view of profit-making, the consulting engineer was not in every way a most desirable person to give advice; being pre-eminently an engineer, he would naturally not look so much to the commercial aspect of the undertaking as he would to the engineering side. It should be remembered that for an engineer commercial knowledge is in some ways a disadvantage. Undoubtedly there is another side to the question, but in successful engineering money may have to be a secondary consideration, and therefore it is not to be expected that consulting engineers should be good commercial men. It is well known that consulting engineers are paid a percentage on the capital outlay, and, therefore, while for not one moment suggesting that a good consulting engineer would on this account recommend increased expenditure, still it must not be forgotten that this percentage does not depend upon the commercial success of the undertaking. Furthermore, the number of consulting engineers who had actually designed, put down, run, and made a commercial success of an electricity supply station was, and is still, limited.

The old Latin proverb *Experientia docet* has a great deal of truth in it, and unless a man is a Heaven-born genius, of which there are few examples in this world, he is not likely to be well acquainted with matters of which he has not had previous experience. However, for local authorities there was no choice in the matter; they had to go to the only men available to advise them with regard to putting down their works. These engineers would be inclined to follow the principle adopted frequently in gas and water works, and erect fine handsome buildings, which are all very well in their way, but do not reduce the cost of manufacture. Further, these engineers took far too limited a view with regard to the supply of electricity in the future. Stations were designed purely for lighting purposes, and too frequently no provision was made for large

* Paper read before the Birmingham Electric Club.

Digitized by Google

future extensions. Further, these engineers who designed the stations apparently favoured land practice rather than marine practice. It is, of course, well known that it is more important to have highly economical engines on board ship than on land, because in the former case not only has coal frequently to be purchased at foreign ports at an enormous figure as compared with the prices ruling in England, but for every ton of coal not required a ton of cargo can be carried. Marine practice was, therefore, to use the most efficient steam-engines possible. Compound condensing engines had given place to the triple-expansion condensing engines, and these in many cases had been superseded by quadruple expansion engines. Engineers who designed the electricity works, for the most part, ignored all this experience and installed compound engines non-condensing, either horizontal or vertical. Of course, these were cheap to buy, and as long as electricity was only used to meet the luxury demand for lighting, the load factor of the plant being only some two hours per day, the want of economy of this type of plant was not of so much account.

Gradually, as the small provincial towns went in for the supply of electricity, it was found that the purely luxury demand was not large enough to make the undertakings pay, so it became necessary to see what could be done to remedy this. It is well known that Mr. Wright at Brighton was the first person to thoroughly grasp the trouble and design a remedy. He soon saw that if the plant could be run fully loaded for twice the length of time per day that the energy could be made much cheaper, and that as long as the standing charges were covered a very low price could be charged for the actual energy supplied. To meet this case, he, in conjunction with the late Mr. Reason, brought out the maximum demand system. This served a most useful purpose. It, however, did not do all that was hoped, but perhaps this was partly due to the fact that the price for the first hour was frequently not made high enough, and the price for the subsequent hours was not made low enough. It is not improbable that the high costs of manufacture had something to do with this, because with the station costs standing at, say, 2½d. per unit, engineers hesitated at offering current at 1d. per unit, say, after the first hour at 8d. Partly, too, the system failed because of the inherent dislike of the Britisher to a new thing, and the word "maximum" was strange to people, and they would not take the trouble to understand the system, though probably in principle they were using it in their own works. This system did undoubtedly tend to improve the load factor of the stations, but, due to the too often inefficient plant, improving the load factor did not improve the financial position of the works in that degree which it would have done had the cost of manufacture been reasonably low.

About this time various schemes were brought forward for the purpose of improving the financial position of the various works: (1) Batteries were suggested to deal with the peak. (2) Various-sized plants were installed, in order that as the load increased or diminished the plant could be changed so as to keep the load factor high on the plant in use. This was very necessary, because the plant which had been installed was too often very inefficient except at top load. (3) Some places shut down during the daytime or ran off batteries only. (4) Other places put down separate condensing plant in conjunction with the then existing engines. A paper was read the other day from which it would appear that in the South of England many stations which are non-condensing produce energy at a lower cost than those that are condensing; this is, of course, due to the poorly-designed condensing plant. All these measures, as will be readily understood, did not tend to the production of large quantities of current cheaply, so that it could be sold at a reasonable figure for industrial purposes. The prices charged for electricity for power purposes were ridiculously high; in fact, it seemed as if everything was being done to put difficulties in the way of consumers obtaining a supply of electricity for power purposes. Even engineering societies did not look with a kindly eye on papers which brought out these points. A paper was written for a certain society by a manager who had the audacity to say that the industrial demand had not been obtained because the industrial demand had not been catered for. 6d., 4d., and 3d. per unit for energy were the prices ruling at the time the paper was written, which paper, I need hardly say, was rejected because it was too progressive.

In 1893 it became the duty of the author to design the station at South Shields, the area of which is shown. There was plenty of cheap land to be obtained near to the area where the principal lighting customers would be. This policy—viz., to put down a small non-condensing station just to deal with the lighting customers—had been too often followed, but in this case the committee was wise enough to wait some 15 months to obtain a site on the river where there was water for condensing purposes and an alternative supply of coal. Though this site was far more costly than the previous one would have been, and though we had to run some 1,100 yards before the first customer was reached, the position chosen enabled the station to be designed for lighting, power, and tramway purposes. The *power* has not yet been developed, and the tramways are only just being put in hand. But even though the load on the station has only been a lighting load, this broad policy of choosing a site where water can be obtained for condensing purposes has been fully justified. A departure was also made in the type of plant installed. It should be remembered that this station was designed in 1893. Instead of the small non-condensing steam plants which were generally used at that time, and which had a very short range of economy, larger plants, surface condensing, were installed. These plants were specially designed for economy over a long range of power. The following figures will show you how economical they were:

*Test of Two 200-kw. Plants at South Shields.*

| | A. | | | | |
|---|---|---|---|---|---|
| Kilowatt-hours | 225 | 192 | 150 | 100 | 56 |
| Water per kilowatt-hour | 22·39 | 21·79 | 22·6 | 23·15 | 28·9 |
| Average of five loads | $\frac{118·75}{5}$ = 23·74lb. per kilowatt-hour. | | | | |
| Average of three loads | $\frac{67·54}{3}$ = 22·51lb. per kilowatt-hour. | | | | |

| | B. | | | | |
|---|---|---|---|---|---|
| Kilowatt-hours | 228·5 | 193·6 | 152 | 95·16 | 54·25 |
| Water per kilowatt-hour | 21·88 | 21·75 | 22·11 | 24·7 | 28·26 |
| Average of five loads | $\frac{118·7}{5}$ = 23·74lb. per kilowatt-hour. | | | | |
| Average of three loads | $\frac{66·36}{3}$ = 22·153lb. per kilowatt-hour. | | | | |

By having such a long range of steam economy it was not necessary to instal the small plants for day-load purposes then so often used. If we think for one moment, we will see at once how much more convenient plant of this description is—viz.: (1) it occupies far less room; (2) owing to its economy, the boilers, pipes, pumps, etc., occupy also less room and cost less; (3) there was no necessity, as the load increases or diminishes, for the staff to be rushing about the place because a few amperes come on or go off. Motors are no trouble with plants of this description. There was a certain station having small non-condensing engines where they obtained an order for two 30-h.p. motors, which were used very intermittently, and so much effect had these on the lighting load that the station superintendent had to ask for 10 minutes' notice before they were started, and had to request the consumer not to use them on top load.

The following results will, I think, show the economy of the working of these plants. I have chosen three stations, all on rivers and all buying coal from the same coalfield—viz.: (1) Newcastle-on-Tyne, with turbines; (2) Sunderland, with enclosed high-speed engines; (3) South Shields, with open-type slow-speed marine engines.

*Comparative Works Costs.*

| Name of town. | Comparative output. | Works costs. |
|---|---|---|
| | 1900. | |
| South Shields | 501,839 | 1·08 |
| Newcastle and District | 1,160 649 | 1·39 |
| Sunderland | 640,579 | 1·46 |
| | 1901. | |
| South Shields | 755,826 | 1·22 |
| Newcastle and District | 1,619,671 | 1·22 |
| Sunderland | 1,318,768 | 1·32 |
| | 1902. | |
| South Shields | 985,646 | ·92 |
| Newcastle and District | 2,058 804 | ·94 |
| Sunderland | 2,375,557 | 1·11 |
| | 1903. | |
| South Shields | 1 148,965 | ·76 |
| Newcastle and District | 2,649,841 | ·82 |
| Sunderland | 2 848,285 | 1·05 |
| | 1904. | |
| South Shields | 1,299 289 | ·65 |
| Sunderland | 3,508,139 | ·92 |

The chief thing we have to bear in mind with regard to the supply of electricity for power purposes is that the energy must be sold cheaply. In order to do so we must get down to the rock bottom cost of manufacture. In considering this question, the *capital* cost of the plant is really a secondary consideration, because if the plant is run 12 hours per day the capital is not increased, but, on the other hand, the maintenance is probably increased, the wages are increased a little, the oil is not increased much. The chief item we have to consider is the coal consumption, because after the stand-by charges are paid the coal consumed will be in proportion to the number of hours the plant is run. The author particularly wishes it to be understood that he does not mean that the open-type marine condensing engine is the *only* engine for use in power stations. The moderate-speed enclosed type and the turbine under certain circumstances will probably do equally as well, but local conditions will decide this.

The following hypothetical case will show which is the more important to consider: the steam consumption of the engines or the capital cost. Assuming 1,000-kw. plant running 12 hours per day for 300 days in a year. A set takes 25lb. of steam per unit, B set takes 35lb. of steam per unit. Assuming that best

Digitized by Google

Welsh coal costs 30s. per ton, and evaporates 10lb. of water per pound of coal, then

$$\frac{\text{Lb.} \quad \text{Kw.} \quad \text{Hours.} \quad \text{Days.} \quad \text{Price.}}{1 \times 1{,}000 \times 12 \times 300 \times £1.\ 5s.} = £2{,}410.$$
$$2{,}240$$

Therefore B plant costs £2,400 per annum more to run than A, or, capitalised at 6 per cent., £40,000.

This question of cost of manufacture is clearly shown by a list of 64 places, *all* of which have a larger output than that at Coventry, with a larger cost of manufacture. This list shows that some £731,873 per annum might have been saved if the costs had been as low as at Coventry. Many of these places have a very much larger output than Coventry. Several have a much better load factor. Several, too, are better situated with regard to the coal supply. Therefore, it is not unfair to assume that had they all been designed on a broad basis and managed commercially that the average cost would not have exceeded that at Coventry, where we have no very special advantages, and where, in fact, one-third of the plant is quite old-fashioned.

About 1898 triple-expansion engines, condensing or non-condensing, were being put down in the larger stations, but even at a later date than this the advantage of having highly efficient plant was not fully grasped. An instance probably is well known to all of you, where a central-station engineer, in putting down a station for power supply, chose rather to put this station on the top of a hill from which the Jordan was clearly visible a couple of hundred yards away, rather than put it down on the side of the river with the water and an alternative supply of coal available. In view of this fact, I trust you will excuse me so strongly emphasising the necessity for plant of the highest effi iency being installed in stations which intend to deal with a supply for power purposes. At the present time, of course, in larger stations, this is well understood, but we have unfortunately a great number of stations throughout the United Kingdom the plant in which is not as economical as it should be, and it is these stations which have hesitated to go in for a cheap supply of energy. The author hopes before he has finished this paper to convince the gentlemen in charge of these stations that it can be done successfully even in these cases.

The question now comes, *Is* the supply of electricity for power purposes at a very cheap rate advantageous, and, if so, to *whom?*

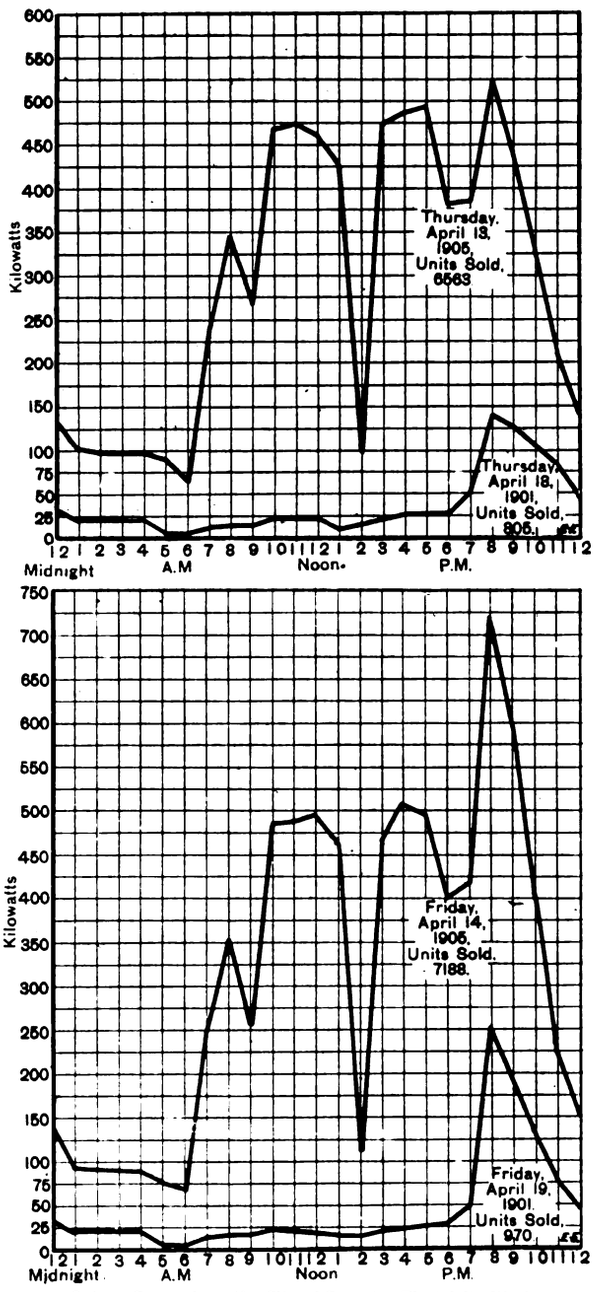
1. *From the Point of View of Patriotism to our Empire.*—It is generally admitted that the British manufacturer has to face very severe competition from goods manufactured abroad. It is, therefore, clearly a duty which we owe to our country to assist the British manufacturer in every way we can. Patriotism to our Empire demands it. Surely we can do this by giving the British manufacturer cheaper methods for producing his goods. That the supply of cheap electrical energy is considered by manufacturers to be an advantage is clearly proved by the thousands of horse-power of electric motors which are being installed by the hard and level headed manufacturers on the Tyne. It is inconceivable that these men would adopt electric driving unless it showed in actual working a considerable advantage, provided, of course, the electricity is supplied at a reasonably cheap rate. It is a curious fact that the first company in England to supply electric energy for power purposes on a large scale was a gas company—not an electric company — viz., the Walker and Wallsend Gas Company. Therefore, from the point of view of patriotism to our Empire, we should advocate and assist in every way we can a cheap supply of electric energy.

2. *From a Point of View of Civic Patriotism.*—We all know that many industries are dying out in the smaller towns. This is undesirable, because the sanitary conditions are likely to be better in the smaller towns and it is a much more healthy and convenient state of things to have a large number of small industrial centres instead of a few large ones. Probably the greatest factor in keeping works in small towns and inducing the industries to start there, is the supply of cheap power, power which can be obtained without the large expenditure necessitated by the use of boilers, steam-engines, chimneys, etc. You will, therefore, see that from a point of view of civic patriotism it is desirable that each inhabitant of a town should do all he can to assist in causing a cheap supply of electrical energy to be given in that town.

3. *From the Health Point of View.*—We all know that one of the greatest problems which is facing us at present is "the housing of the working classes." Nothing holds out as a great possibility for overcoming the difficulty of carrying the worker away from his work in the evening to sleep and live in a healthy atmosphere as electric traction: this will be materially assisted by the supply of cheap electric energy. We all know that municipalities are spending large sums of money on sanitary arrangements. Surely it is a desirable thing that those who have to be at work in a close and too often confined space should have the best atmosphere that can be provided, whether by non-vitiation of the air or by easily-adapted methods of ventilation. It may be of interest to you to know that the author visited a factory within the last fortnight, which factory had been driven previously by gas-engines, but now it is entirely driven by electric motors. The manager told me that it was no uncommon thing to have three or four girls carried out in an afternoon in a fainting condition at the time when the works were being driven by gas-engines, but they had not had a single case of this sort occur during the last 18 months that their works had been driven *exclusively* by electric power.

4. *From the Point of View of the Manufacturer of Electrical Apparatus.*—Surely he would, indeed, welcome the supply of cheap electric energy in the various towns in the United Kingdom, as this would mean increased demand for cables, motors, etc.

We, therefore, see that from the point of view of patriotism to our Empire, from the point of view of civic patriotism to the town we live in, from the point of view of the health of the working classes, from the point of view of the manufacturer of electrical apparatus, that the supply of cheap electrical energy for power purposes is a thing to be most desired of men.



Output Curves from the City of Coventry Electricity Works, showing growth of Day Load.

The only point which I think now requires to be proved is whether this supply of electrical energy cheaply will be a benefit to the supplier, or, as the Act puts it, the undertaker—viz., the owner of the electricity supply works—and this is the question which I propose to deal with next. During the year ending 1902 it became the author's duty to take over the management of the electricity works at Coventry. I would, in passing, wish to say that I should prefer to have given figures other than those at Coventry, but unfortunately they are not at my disposal; but I consider that what the staff has been able to accomplish there can be accomplished anywhere else, providing they work together hand in hand in the way they have done at Coventry, and spell the word "can't" without the "t." The difficulties we have had to contend with have

| 1903 | 102,712 | 566 731 | 7 959 | 3,573 | 1·51 | 4,385 | 4 84 % | 3·37 |
| 1904 | 119 470 | 920 192 | 10 695 | 4,449 | 1·16 | 6,246 | 5·62 % | 2·78 |
| 1905 | 134 503 | 1,375,735 | 13,111 | 4,883 | 85 | 8,228 | 6·47 % | 2·28 |

merely induced us to further efforts, and really when one comes to look back upon what has been accomplished, it is surprising to see how small the difficulties really were. Table A will show you the position the works were in and the alteration now. It should be clearly remembered that during the first four years of running the trade in Coventry was good ; in fact, for the first two years it was extremely good, but for the last four years it has been the very reverse. You will notice that for the year ending 1900 the gross profit on the average capital spent was 1·44 per cent., and the average price obtained was 4·27d. per unit. I would prefer to leave out of account the two years ending 1901 and 1902, because the coal was abnormally high during these years, due in a great measure to the way in which the contract was placed.

When the author took over the management it was very evident that a very considerable amount of capital had been spent in proportion to the *earning* capacity of the station. The plant was of an uneconomical type, and there was no inclination, but rather the reverse, on the part of the ratepayers of Coventry to support the electricity undertaking in Coventry. Prices were lowered, being reduced to 1d. for the third hour on the maximum demand system, but this did not have the effect which it was hoped it would have had, due to certain causes, among which was the system of free wiring whereby the more current a man used the more he would pay for the wiring. The long-hour consumer did not seem desirous of taking the light, and we were, therefore, face to face with this position. The author had advised the Corporation, in spite of the very large deficit for 1901, to lower the prices and double the capital. It probably was a very drastic course to take, but from figures which the author would be pleased to place before anyone it was obvious the *only* course to take. The standing charges against the then existing plant were so high that unless the capital was, as it were, watered by well-spent capital, the capital cost per kilowatt of earning capacity made it impossible to make the undertaking pay.

You probably all know that there are a very large number of gas-engines in Coventry. It stands, I believe, the second town in the United Kingdom as having the largest number of gas-engines in proportion to the population. Well, the only course to adopt was to go in for the supply of electric motors, but the difficulties in the way were : (1) that a very low price would have to be charged for the energy because of the competition with the gas-engines, and (2) the firms were too often too badly off to afford any money to buy the motors, so it therefore became necessary to hire them out. This practically meant starting an entirely new business. Consumers had previously been told that the motors would not answer, and it was therefore necessary to disabuse the mind of the would-be consumer on this point, and we had to frequently instal the motors, do the wiring, fix the countershafting, belts, etc.—in other words, we had to do everything we possibly could to obtain customers and keep them. I am bound to say that as a whole the consumers at Coventry were not so disposed to go in for a new thing as people in some parts of England are, but we have, in spite of all this, done fairly well. The majority of the motors have been put on since the end of 1902—that is to say, during the last three years. At the end of 1902 we had something under 100 h.p. of motors connected ; now we have over 1,150 h.p. of motors connected.

As probably you are aware, the old system at Coventry was 87 periods single-phase with a *plant* capacity of 600 kw., earning capacity 350 kw. This plant was retained, and was kept to supply current to the centre of the town, where there are practically no motors. The area outside the centre of the town was changed over to 50 periods two-phase. The plant installed was of the same kind as at South Shields. I am afraid I cannot give you full details of the engineering side of the undertaking now for two reasons : (1) because time will not allow me to do so ; (2) it hardly comes within the scope of the present paper, the object of which is to prove that power can be supplied at a cheap rate for industrial purposes with considerable advantages both to the supplier and to the supplied regardless of the system of supply. However, I may mention that the difficulties in the way of changing over single-phase to two-phase are to a great extent chimerical. It was astonishing to see how little was known in England by the English manufacturer about two-phase working when we decided to change over. We drove ahead and the difficulties disappeared. It was supposed there would be trouble in balancing the sub-stations ; there was none. Difficulties with the old mains were prophesied, but these have yet to be discovered. The first thing that I had to do, and what I would most strongly emphasise you to do first, is to reorganise the books kept, so that month by month, quarter by quarter, we shall know exactly where we stood.

The log sheet shown is the one adopted by the author. You will notice that there are two sides—the right-hand side is for this year's working, and the left-hand side is for the corresponding period of the year before. A wages book, invoice book, and a ledger will allocate everything, which is then transferred to the log book—a method which anyone can understand. This undoubtedly is the first thing to be done to improve the financial position of the station, to keep the books in such a way that at any time the exact position can be seen. The effect upon the station costs has been, as you see, very marked—viz., the station costs for 1900 were 3·43d. per unit, whereas for 1905 they have been brought down to ·85d. per unit. Of course, the true criterion of the financial position of the undertaking is shown by the gross profit made on the average capital spent. This in 1900 was 1·44 per cent., and in 1905 was 6·47 per cent. You will notice that for 1900 the average price obtained was 4·27d. per unit, the average price obtained for 1905 was 2·28d. per unit.

I think no words of mine are necessary to show how great a success has been obtained by adopting what we may call ordinary commercial methods in dealing with a corporation undertaking. Among these I mean the obtaining of orders and the treatment of customers. If we had waited for orders to come to us, we should have had practically none. If orders would come in without being looked after, why is it that hundreds of thousands of pounds are paid every year to people who obtain orders. The capital has been increased from £63,565 in 1900 to £134,503 in 1905, an increase of £70,938. Deducting £787, the gross profit made in 1900 on £63,565. from the gross profit this year, we have made £7,440, being 10·4 per cent. on the *extra* capital spent.

In conclusion, the author wishes to say that he feels sure that what has been done at Coventry can be done elsewhere, providing that the same methods are adopted, and the same loyal support is given to the manager as the author himself has received from the various members of his staff. It is impossible for the manager to be everywhere, and a great many of the economies effected have been the direct result of the care and pains taken by his assistants.

## INSTITUTION OF ELECTRICAL ENGINEERS.

At the meeting on the 5th inst. Mr. A. M. Taylor's paper, read before the Birmingham Local Section on Dec. 14 last, was discussed in its amplified form. We gave an abstract of the original paper in our issue for Jan. 15, and the amended paper was dealt with in our issue of the 5th inst.

The subject having been introduced by the author, Mr. C. P. SPARKS expressed dissent upon one or two points. He considered the author had exaggerated the competition between electric and other motors. The electric motor was the motor of the future, in many cases the consumer of power having no option but to employ electric energy. The diversity factor for lighting was poor, but for a power load it was considerably higher than had been assumed by the author, who had also overstated the capital charges. He considered that the author had in general put the cost of generation at too high a figure.

Mr. W. C. P. TAPPER found himself quite at variance with Mr. Taylor regarding the restricted-hour system, which he (Mr. Tapper) had found quite practicable at Stepney. He echoed Mr. Sparks's view that the author's assumptions as to diversity factor were incorrect, instancing the 4·4 (which is increasing) at Hackney, and the Glasgow tramway load of 7·75.

Mr. J. S. HIGHFIELD thought the tone of the paper too pessimistic,

Digitized by Google

as, in his opinion, the authorities were selling energy at rates which answered the purpose of the consumer. As to the overlapping of lighting and motor loads during fogs, the author estimated this at 60 per cent. The Metropolitan Company found that it amounted to 80 per cent., which would represent an increase of capital charges. He thought it important to calculate the load factor upon a weekly instead of an annual basis when calculating costs, because the increasing connections caused the load factor to be higher per week than per year, which placed a more favourable complexion upon the accounts than when they were calculated upon an annual basis. A system necessitating the running of separate circuits for motors and lighting to a consumer's premises would be inconvenient. In the case of combined plants fogs would shut down the tramways while increasing the lighting load, so that overlapping would not occur.

Mr. JECKELL did not think the author's figures accorded with practice. Figures were given by the speaker in support of the superiority of electric motors over gas-engines. He instanced a case in which a firm had replaced a 36-h.p. gas-engine by electric motors, and had effected a saving of £11 for a quarter, irrespective of the economy in water cost and floor space.

Mr. VIGNOLES deprecated a reduction upon 1d. per unit for power. Comparing the cost of operating with a gas-engine and an electric motor, he found the results favourable to the former, and, moreover, a motor running nine hours per day would probably have a variable load, thus introducing a diversity factor. The author's suggested prices for restricted-hour supply were much too low. In Grimsby, where they had a sliding scale and a restricted-hour system, a large proportion of their power customers used the latter, though after a time they usually discovered that the sliding scale was more advantageous. The restricted-hour arrangement, however, provided an excellent attraction. He preferred battery sub-stations to isolated accumulators.

Mr. R. A. DAWBARN considered that motors should take a fair ratio of capital charges in proportion to the peak load. For many classes of restricted-hour consumers, 1d. per unit was scarcely low enough. The Huddersfield Corporation had accepted a consumer at ½d. per unit, and it would need a much lower figure than 1d. per unit to tempt cotton-mill proprietors, who for a mill using, say, 1,300 h.p. only stood at a cost of ·231d. per horse-power for their power at present.

In reply, Mr. TAYLOR stated that he thought everyone would agree that in the case of a number of motors all fully and continuously loaded the diversity factor was unity. With any cyclic load factor of motors the diversity factor of the station was the reciprocal of that load factor, assuming all motors to be of the same class, and that the cyclic load factor of the station was equal to the motor load factor multiplied by the diversity factor. He contrasted the poor results obtained at Stepney on the restricted-hour system with the phenomenal success which had attended it at Brighton. Regarding the list of figures which had been given by Mr. Jeckell, he thought it would be found that the brake horse-power hours were over-estimated, which would account for Mr. Jeckell's figures being so low. It appeared to him that lighting and power loads could be treated on the same basis, with equivalent demands, and he thought the restricted-hour system was practicable for many industries.

# LEGAL INTELLIGENCE.

## TELEPHONIC INTERCOMMUNICATION.

In the Chancery Division last week, Mr. Justice Buckley delivered his reserved judgment in the action brought by the Swansea Corporation against the National Telephone Company.

HIS LORDSHIP said he understood this was the first case in which application to the Court had been made to construe or enforce the Telegraph Act of 1899 in reference to intercommunication between competing telephone systems. The question arose under Sub-Section 5 of Section 3, which provided that when the license of an existing company was extended in respect of any exchange area for a period of eight years the company should, at the request of the new licensee of the Postmaster-General, afford all proper facilities for transmission of telephone messages over both systems, provided that the licensee requiring intercommunication should in any such case afford similar facilities. Before September, 1902, the defendants had a system of telephonic communication in the Swansea area, and in September, 1902, the Postmaster-General granted a new license to the plaintiffs, at the same time extending the defendants' license. By November, 1903, the plaintiffs had established their system, and in January, 1904, requested intercommunication, and duly satisfied the Postmaster-General that they had the required number of subscribers. Mr. Gaine had admitted in the box that the defendants desired to raise every objection that could be legitimately put forward to prevent the plaintiffs obtaining the intercommunication they had a right to request and had requested. They had got the benefit of their extended license, but intended to put every obstacle in the way of the new license. Many of the objections were not now relied on, but these remained. The defendants had a central exchange at Swansea and 11 or 12 subsidiary exchanges, and they required that the plaintiffs should provide junction circuits to connect directly the plaintiffs' exchange at Swansea and the defendants' exchange there and with each of nine other subsidiary exchanges, and also junction circuits to connect the Mumbles and Morriston exchanges. The defendants contended that the lines must be duplicated from plaintiffs' exchange to each of the company's subsidiary exchanges. There was no justification for that in the Act. The object of the Act was not to duplicate systems, but that the customers of each company should use the other's trunk line. In the result he declared that under Section 3, Sub-Section 5, of the Telegraph Act, 1899, and the order of the Postmaster-General, and in the facts which had happened, the plaintiffs were entitled to be afforded by the defendants all proper facilities for restricted intercommunication, within the meaning of the order, between persons using the defendants' system and persons using the plaintiffs' system, and he declared that the defendants had refused to give such facilities, and there would be an order that the defendants do give such proper facilities, with liberty to either side to apply to the Court in case any difficulties arose, the defendants to pay the costs of the action.

## WORKMEN'S COMPENSATION ACT.

### Back v. Dick, Kerr, and Co.

An appeal came before the Master of the Rolls, Lord Justice Mathew, and Lord Justice Cozens-Hardy, in which the defendants sought a reversal of the award of compensation made by Judge Lush-Wilson, K.C., sitting at the Exeter County Court. The defendants had entered into a contract to take up the old tramway rails in certain streets in Exeter, and lay down new rails for tramcars to be worked by electric power. The plaintiff was employed in assisting to unload rails from a truck and to stack them there by means of a hand crane, when he was injured by an accident. At the time of the accident the only work under the contract then commenced was that of taking up the old rails in the street on the St. David's Station side of the clock tower, about 700 yards from the place where the accident happened. The question was whether the plaintiff was at the time of the accident employed "on, or in, or about engineering work," engineering work being defined as meaning "any work of construction or alteration or repair of a railroad. . . ." The county court judge, in giving judgment, said: "I have come to the conclusion that it would be impossible to limit the meaning of the words 'engineering work' to the extent contended for on behalf of the employers" (that was, that "engineering work" imported definite locality, and that the engineering work in question must be limited to the portion of the line in course of construction, and could not include storing places or depôts). "Although the word 'work' imports definite locality as meaning the thing on which the labour is bestowed, I think the words 'on, or in, or about engineering work' must include any portion of the selected area upon which the essential operations were conducted. I find that the site upon which the rails were stacked in the yard was on, or in, or about the engineering work," and he accordingly made an award in favour of the applicant.

The COURT allowed the appeal.

The MASTER OF THE ROLLS said that the question of whether the plaintiff was at the time employed on, or in, or about engineering work depended upon the definition of "engineering work" in Section 7, Sub-Section 2, of the Workmen's Compensation Act, 1897, and the decisions of this Court as to the meaning of that term. Previous judgments were to the effect that the term "engineering work" in both limbs of the definition denoted the physical locality where labour of a certain class was being bestowed. It indicated a physical area, and to come within the Act the workman must be employed on, or in, or about that physical area. In the present case the physical area of the engineering work which was actually being carried on at the time was about 700 yards from the scene of the accident. Unless it could be said that the railway yard was part of the physical area of the engineering work, the case did not come within the Act. The learned judge's view was that the railway yard could not be so construed.

Lords Justices MATHEW and COZENS-HARDY concurred.

## FURIOUS DRIVING.

Two motormen in the employ of the Glasgow Corporation tramways department were fined a guinea each last week in the local police court, the charge being furious driving. The circumstances were somewhat exceptional. The cars were proceeding in the same direction, and the accident which resulted in their collision seems to have arisen through each driver trying to reach a junction first. The Magistrate said that although one of the motormen had the right-of-way according to the regulations, these regulations were for guidance, and not for exoneration in the event of an accident.

# COMPANIES' MEETINGS AND REPORTS.

## BRUSH ELECTRICAL ENGINEERING.

The annual meeting of this Company, whose report appeared in our issue of the 5th inst., was held at Salisbury House, London, last week, Lord Vaux of Harrowden presiding.

The CHAIRMAN said that during the past year they had been actively engaged upon very necessary development work in the various departments at their Falcon Works, which were calculated to increase their profits in future years, but which, for the time being, were having just an opposite effect, as the cost had to be met out of revenue. The salient features of the year's business had been the sustained activity in their rolling-stock departments and the growing strength of their mechanical engineering and electrical business. They had executed large rolling-stock orders for various municipal and other tramway undertakings, and they had now completed the delivery to the Metropolitan District Railway of cars and trucks which represented the highest class of electrical railway vehicles yet constructed for service in this country. In view of the electrification of other railways they had made preparations for handling large orders of this description. To meet the growing demand for railway and tramcars and motor omnibuses that would not catch fire, they had laid down plant for the chemical treatment of timber on the most approved principles,

Digitized by Google

and the District Railway coaches had all been built of this material. Designs had been completed for a new type of all-steel car, which possessed marked advantages in the saving of weight, and which in other ways tended towards the reduction of traffic expenses. In the manufacture of tramcars they had maintained their position as the leading firm engaged in the industry. The net profit available was practically the same as in the previous year, and the appropriation recommended by the Board was as before. The immediate future of the Company's business appeared more cheerful that when he last addressed the shareholders. They were better organised for both manufacturing and selling, and their goodwill not only throughout the United Kingdom and the Colonies, but in foreign countries, was steadily improving. Taking a general survey of the position, it was felt by the directors that the prospects in the immediate future were such as not to give rise to the anxiety which they had experienced in the past.

The report was eventually adopted.

## CRAIGPARK ELECTRIC CABLE.

The second annual general meeting was held at Glasgow last week, Mr. James T. Tullis presiding. The report, which was adopted, recommended a dividend for the half-year ended March 31 of 6 per cent. per annum on the preference paid-up capital, in addition to an interim dividend already paid to the preference shareholders for the half-year ending Sept. 30, 1904; £300 had been written off preliminary expenses, £1,000 depreciation written off buildings and machinery, and a balance carried forward of £1,018. 9s. 10d.

## CALLENDER'S CABLE AND CONSTRUCTION.

The report for the year ending Dec. 31 shows a balance at the credit of profit and loss for the year's working of £57,065. 15s. 2d., to which has to be added the balance brought forward from 1903, £24,581. 3s., making together £81,646. 18s. 2d. From this must be deducted interest on debenture stock, £11,250; dividend on preference shares, £10,000; appropriation for depreciation of plant and machinery and office furniture, £12,337. 11s. 1d.; and also the balance of cost of the issue of debenture stock, £2,777. 14s. 1d.; leaving an available balance of £45,281. 13s.—which it is proposed to deal with in the following manner: (1) by the payment of a dividend on the ordinary shares at the rate of 10 per cent. per annum (clear of income tax), £17,500; (2) by the payment of a bonus of 2s. 6d. per share, £4,375; (3) by carrying forward to next year's account, £23,406. 13s. In spite of a considerably reduced volume of business, the profits have been over £4,000 in excess of those of last year. Important contracts have already been secured at home and abroad to be carried out this year, and the factory at Erith will be kept busy for some time to come with the orders actually in hand. The Company has carried out a large amount of work in connection with the supply of electric power in South Wales, in the Cleveland district, and in Yorkshire. The directors state that practical experience has shown that the policy adopted two years ago in regard to the companies supplying large areas with electricity under parliamentary powers is a sound one. Further extensive orders are in course of execution for additional mains in these districts, and for new power mains in Lancashire, Derbyshire, Fife, and elsewhere. During the past year a considerable extension of the Company's business has taken place abroad, especially in the East. Cable-laying contracts have been completed or are in progress in Bombay, Calcutta, Kandy, Penang, Kuala, Lumpur, Singapore, and Hong Kong, whilst further orders are now in course of execution for Bangkok and the Kidderpore Docks. Contracts have also been carried out in New Zealand, at Wellington and Dunedin. Considerable orders have been executed in Mexico, and the Company's staff is now cable-laying in the Argentine. In conjunction with other well-known firms in the engineering trade the Company has taken part in the establishment of the British Engineering Company of Egypt, Limited, with the view of securing satisfactory representation in that country when the time comes for the execution of heavy electric contracts there. The Company is now reaping considerable advantage from the expenditure on plant and appliances made at the factory during the past five years. It has thus been possible to produce cables at a profit during the difficult and trying time through which the Company has passed. The machinery, plant, and equipment at Erith and on outside contracts have been maintained in the most efficient condition, the cost thereof being debited to the year's revenue. The directors call attention to the heavy burden upon this Company from the local rates and taxes, the amount payable having been considerably increased during 1904. At Erith alone the sum paid amounts to £3 741 per annum, equal to a dividend of 2¼ per cent. on the ordinary share capital of the Company. The operations of the Anchor Cable Company, Limited, whose shares are held by this Company and its nominees, have been considerably restricted during the past year, owing to the unsatisfactory position of the rubber trade, due to the unprecedented advance in the cost of raw materials, with no corresponding increase in selling prices. The policy of the Anchor Company has therefore been a waiting one, but the plant and machinery at Leigh have in the meantime been put into excellent order, and the trade connection has been considerably increased. It has been shown by events which have occurred during the past year that the control of the Anchor Works has already been of great advantage to the Company's business, and the directors are confident that it will continue to be so. As anticipated at the time of purchase, the clearing up of the contracts undertaken by the old management has been attended with heavy expenditure. A sum has been set aside out of the Company's profits towards meeting the loss thus caused, which will be dealt with when the Anchor Company is finally incorporated with the Company. A further issue of debenture stock amounting to £100,000 was made during the past year, and was readily accepted by the investing public. The directors regret to announce the death of Lieut.-Colonel Elliot, which took place in July, 1904. The vacancy thus caused has been filled by the election of Sir J. Fortescue Flannery, Bart., M.P. Major W. M. Mackenzie is the director retiring by rotation, and he being eligible offers himself for re-election.

## GLOBE TELEGRAPH AND TRUST.

The report for the year ended April 30 states that the net revenue, after deduction of expenses, amounts to £199,123, and makes, with the balance brought forward, a total of £202 180. From this amount there has been distributed a sum of £131,709 in interim dividends, leaving an available balance of £70,471. The directors now recommend a final dividend of 3s. a share on the preference shares and of 4s. 9d. per share on the ordinary shares, making, with previous distributions, total dividends for the year of 6 per cent., less tax, on the preference shares, and of 5⅝ per cent. net on the ordinary shares, leaving a balance of £1,643 to be carried forward.

## SUBMARINE CABLES TRUST.

The report for the year to April 15 states that the revenue for this period amounted to £24,288 and the expenses to £1,161, leaving a balance of £23,127. After providing to meet payment of the coupons, £3,976 had been transferred to the redemption fund, leaving £92 to be carried forward. In accordance with the terms of the trust deed, 34 certificates have been redeemed since the last report by purchase in the open market.

## LIENS REGISTERED.

**British Electric Traction Company, Limited.**—Particulars of a series of debentures, created by resolution of June 16, 1898, securing an amount equal to half the subscribed capital for the time being, have been filed in accordance with Section 14 (4) of the Companies Act, 1900, a debenture of recent date having been produced at time of filing. Property charged: the company's undertaking and property, present and future, including uncalled capital. No trustees for debenture holders. A letter annexed to the return states that these debentures are issued to trustees for holders of debenture stock of like amount, acting under a trust deed, dated June 30, 1898, as modified by a deed of Oct. 6, 1898, and that some debentures of this series have already been registered. The trustees for the debenture stockholders are the Electric and General Investment Company, Limited.

## CONTRACTS FOR ELECTRICAL SUPPLIES.

**Tonbridge.**—The Urban District Council require tenders for cables. Tenders by May 29.

**Ashton-under-Lyne.**—The Corporation invite tenders for six tramcars. Tenders by May 23.

**Llandudno.**—The Corporation invite tenders for switchboard extensions. Tenders by May 22.

**Darlington.**—The Corporation invite tenders for two storage batteries. Tenders by May 23.

**Islington.**—The Borough Council require tenders for coal-conveyors, etc. Tenders by May 24.

**Cataquexes (Spain).** — The local light and power company require tenders for electrical plant. Tenders by July 1.

**Dartford.**—The Urban District Council invite tenders for the supply and erection of various plant. Tenders by May 24.

**St. Marylebone.**—Tenders are invited for the annual supplies in the electricity department. Tenders by May 28. See advertisement in last issue.

**Madrid.**—The Public Works Department require tenders for carrying out a scheme for an electric tramway for goods transport along Bilbao quays.

**Paris.**—The Colonial Office, 4 bis, Rue Jean-Nicot, require tenders for the supply of lamps and lighting accessories for three years. Tenders by May 23.

**Glasgow.**—The Trustees of the Clyde Navigation invite tenders for electric arc-light installation for the outer basin of Clydebank Dock. Tenders by May 22.

**St. Pancras.**—The Borough Council invite tenders for the supply of arc lamp carbons for 12 months. Tenders by May 23. See advertisement in last issue.

**Partick.**—The Town Council invite tenders for the supply of various plant at their electricity works. Tenders by 12 noon on June 6. See advertisement.

**Edinburgh.**—Tenders are invited for steam and exhaust pipework at McDonald-road electricity supply station. Tenders by 10 a.m. on June 6. See advertisement.

**Liria** – The Municipality require tenders for installation of electric lighting; 2,000 c.p. are required for street-lighting, for which it is proposed to pay 6,000 pesetas per annum.

**Edinburgh.**—Tenders are invited for extension of switchboard panel at McDonald-road electricity supply station. Tenders by May 30. See advertisement in last issue.

Digitized by Google

**Krakow.**—The Government Railway require tenders for extensions of their electric station, including additional generators, switchboards, motors, etc. Tenders by noon on May 28.

**Kettering.**—The Urban District Council invite tenders for the supply, delivery, and erection of Nernst lamps, posts, etc., for street-lighting within their district. Tenders by May 29.

**Heywood.**—The Town Council invite tenders for the construction of the permanent way and paving and overhead electrical equipment of about four miles of tramways. Tenders by May 22.

**Laventhem (Belgium).**—The Municipality require tenders for erection of central station, laying of mains, etc. Particulars (3s. 4d.) may be obtained from the Secretary of the Mayor of that place.

**The Hague.**—The Post and Telegraphs Department require tenders for the construction of a telegraph line of 10 wires between Bodegraven and Woddinxveen. The estimate is £478. Tenders by May 24.

**Bristol.**—Tenders are invited for single-phase alternating-current transformers and three-phase to direct-current motor-generators. Full particulars from the City Electrical Engineer, Temple Backs, Bristol.

**Buralem.**—The Corporation invite tenders for wiring the town hall, markets, baths, gymnasium, and Wedgwood Institute, and also for the supply of house service fuses and meters. Tenders by May 30. See advertisement in last issue.

**Madrid.**—The Post and Telegraphs Department require tenders for 50 tons 4mm. zinced iron wire and 5 tons 3mm. bronze wire. The maximum price for the iron wire is 580 pesetas and that for the bronze wire 3,400 pesetas per ton. Tenders by June 5.

**Stalybridge.**—The Stalybridge, Hyde, Mossley, and Dukinfield Tramway and Electricity Board require tenders for the supply, delivery, and erection at the Stalybridge sub-station of a 400-kw. motor-generator, together with the necessary switchgear for same.

**Switzerland.**—M. R. Vontobel, of Winterthour, and M. Charles Probst, of Lucerne, have obtained a concession for the construction of a narrow-gauge electric railway from Meiringen to Gletsch. The total cost of the enterprise is estimated at £241,600; £19,600 is to be expended on rolling-stock.

**Bristol.**—The Docks Committee invite tenders for the construction, delivery, erecting in place, fitting, testing, and maintenance for 12 months after completion, of four two-ton movable electric jib cranes, and one three-ton movable electric jib crane to be erected on the adjoining wharf at Canons Marsh. Tenders by June 7.

**Bangour (Scotland).**—The District Lunacy Board invite tenders for the following works: (1) building in boiler economisers, etc.; (2) building in chimney stalk; (3) building in steam and electric cable trenches; (4) steam boilers; (5) engines and dynamos; (6) economisers and piping; (7) overhead travelling cranes; (8) accumulators; (9) switchboard and connections; (10) main cables and branches. Tenders by May 27.

**London, S.E.**—The London County Council invite tenders for the road work and platelaying required for the construction, for electrical traction on the conduit system, of certain authorised tramways in Blackwall-lane, East Greenwich, and from New Cross to Lewisham, and for the reconstruction, for the same system of electrical traction, of a portion of the existing horse tramways in Woolwich-road, and from Lewisham to Catford. Tenders by 10 a.m. on May 23.

## RESULTS OF TENDERS.

**Hammersmith.**—The Borough Council have accepted the tenders of Mr. C. R. Heap and Messrs. Le Carbone for commutator brushes for the electricity works, at £23. 12s. and £9. 3s. 6d. respectively.

**Weymouth.**—The following tenders have been received for wiring, etc., Sunnybank House: Ekless Bros. and Hine, £65; W. Pratt and Co., £65; W. Gee, £59; C. Tett, £52; W. D. Orchard, £49. 15s. 6d. (accepted.)

**Southampton.**—The Town Council have accepted the following tenders: Wm. Griffiths and Co., London, for the work of reconstructing the Portswood-road section of tramways, £1,711. 0s. 7d.; North Eastern Steel Company, Middlesbrough, 250 tons of tramway rails, £5. 10s. a ton; G. R. Turner, Limited, Notts, two 10-ton coal wagons for the electricity department, £128.

**Woolwich.**—Messrs. Browett, Lindley, and Co., Patricroft, near Manchester, report an order from the Government for the supply of a 500 kw. steam generator, including one of their three-crank triple-expansion enclosed forced lubrication steam-engines, coupled to a dynamo by the British Westinghouse Electrical and Manufacturing Company, to be installed at the Royal Arsenal.

**Southampton.**—The Corporation have received the following tenders for (a) supply of about 250 tons of 7in. girder rails and (b) reconstruction of tramways, Portswood-road: North-Eastern Steel Company, Middlesbrough, £5. 10s. per ton (accepted); Bolckow, Vaughan, and Co., Middlesbrough, £5. 12s. 6d.; R. W. Blackwell and Co., London, £5. 15s. 9d.; Lorain Steel Company, London, £5. 16s.; W. Scott, Limited, Leeds, £5. 5s.

**Metropolitan Asylums Board.**—It has been agreed that, subject to the approval of the Local Government Board, the offer of the Tudor Accumulator Company, to renew the electrical storage battery at the Northern Hospital for the sum of £295, and to maintain it for 10 years for a further sum of £28 per annum, be accepted. This price includes cost of installing a new battery of 110 cells, having a capacity of 370 ampere-hours, and for increasing the size of the 10 existing Tudor cells to make them of the same capacity as the proposed new one, at the sum of £340, less an allowance of £45 for old materials—*i.e.*, £295 in all.

**Govan.**—The Electricity Department have accepted the following, among other tenders, for various stores contracts: J. Macqueen and Co., Glasgow, engine and cylinder oil; Ferguson and Timpson, Glasgow, packing and gauge glasses; British Insulated and Helsby Cables, Limited, cables and accessories; C. Sharp, Limited Glasgow, bitumen and compound; Ferranti Limited, Hollinwood, meters up to and including 25 amperes; Chamberlain and Hookham, Birmingham, meters, all sizes over 25 amperes; Keighley Electrical Engineering Company, Keighley, fuse-boxes; D. Richmond and Co., Govan, wrought-iron tubes and fittings; D King and Co., Glasgow, cast-iron pipes; Crompton and Co., London, carbons; J. Kennedy and Sons, Glasgow, coal; British Thomson-Houston Company, Rugby, motors, 1, 2, and 3 h.p.; Lancashire Dynamo and Motor Company, Manchester, motors, all other sizes; Reyrolle and Co., Hebburn-on-Tyne, Monte-Callow, London, and Brook, Hirst and Co., Chester, motor starters; Berry, Skinner, and Co., London, D.P. switches.

**Carshalton.**—The Metropolitan Asylums Board have received the following tenders for installation of electric light, telephones, and fire-alarms, at the Southern Hospital:

| | | | |
|---|---|---|---|
| Buchanan and Curwen, 64, Victoria-street, S.W.* | £8,600 | 0 | 0 |
| Bromley and Batstone, 24-6, Holborn, E.C. | 8,677 | 4 | 3 |
| Belshaw and Co., 53, Victoria-street, S.W. | 8,944 | 0 | 0 |
| Alliance Electrical Company, Limited, 23, Grafton-street, W. | 9,583 | 17 | 0 |
| F. A. Glover and Co., Limited, Vine-street, Clerken-well-road, E.C. | 9,671 | 0 | 0 |
| Wenham and Waters, Limited, Paragon Works, Croydon | 10,790 | 0 | 0 |
| Drake and Gorham, Limited, 65, Victoria-street, S.W. | 10,819 | 0 | 0 |
| Higgins and Griffiths, 4, Albany-street, N.W. | 10,860 | 0 | 0 |
| Bergtheil and Young, Limited, 12, Camomile-street, E.C. | 11,600 | 0 | 0 |

*Recommended for acceptance.

**London County Council.**—The Council have received the following tenders for the execution of the several portions of the work in connection with the construction of the tramways in Archway-road, Highgate:

| | Tramway construction. | Paving works of street widening. |
|---|---|---|
| Dick, Kerr, and Co. | £4 587 15 9 | £1,010 8 5 |
| D. R. Paterson | 4 807 14 2 | 1,036 11 9 |
| J. Mowlem and Co. | 4 920 2 4 | 1,035 8 7 |
| W. Griffiths and Co. | 4,954 13 8 | 1,034 5 10 |
| R. W. Blackwell and Co. | 5,037 15 8 | 1,104 18 6 |
| Muirhead, Greig, and Matthews | 5,074 14 0 | 1,082 1 7 |

Subject to the approval of the Board of Trade and the Islington Metropolitan Borough Council being obtained to the system of electrical traction proposed to be adopted on the tramways, it is proposed to accept the tender of Messrs. Dick, Kerr, and Co., Limited, the firm to be allowed to sublet to the undermentioned firms (or to such other firm or firms as may be approved by the engineer under the contract) the following portions of the work in connection with the tramways in Archway-road—namely: (1) to the Hadfield Steel-foundry Company, Limited, of Sheffield, the manufacture of the special work for the tramways (consisting of points, crossings, etc.); (2) to the Associated Portland Cement Manufacturers, Limited, the supply of cement; and (3) to Messrs. Bayliss, Jones, and Bayliss, Limited, of Wolverhampton, the manufacture of the tie-bars.

# BUSINESS NOTES.

## TRACTION.

**Bonnyrigg.**—The Town Council have approved Sunday running.

**Doncaster.**—A *plébiscite* is to be taken on the question of Sunday running.

**Darlington.**—The first annual tramway report shows revenue £8,544, while the working expenses, including £2,521 for current, total £6,464.

**Karori (N.Z.).**—The Borough Council are contemplating raising a loan of £29,000 for the purpose of providing a Lombard-Guerin system of electric traction between Karori and Wellington.

**Hastings.**—The company's Bill has been placed on the unopposed list, and it is expected that it will be passed without any trouble. Good progress is being made with the work of construction.

**Bradford.**—At a meeting of the Corporation last week the Deputy-Chairman of the Tramway Committee stated, in reply to a question, that it was not proposed to introduce ½d. fares at present.

**West Cumberland Tramways.**—The Bill seeking a further extension of one year from August next from the commencement of the work of construction has been ordered for third reading in the House of Commons.

**Tranent.**—It is reported that the National Construction Electrical Tramway Company cannot see their way at present to undertake an extension of their system from Levenhall to Tranent, but that they will as early as possible inaugurate a system of motor omnibuses.

**Heywood.**—Apparently the agreement for the working of the Heywood trams by the Bury and Rochdale Corporations will now go through without much further delay, as the Tramways Committe have approved the terms outlined by the sub committee, and the Corporation have approved the action of the Tramways Committee.

**Mansfield.**—The Nottingham-road, Chesterfield-road, and Pleasley Hill sections of the Mansfield tramways are rapidly approaching completion, and the engineers anticipate that the cars will be running by June 1. The metals have been laid part of the way through the Market-place, and the men are now at work on the Westgate section.

Digitized by Google

**Hythe.**—A proposal for a system of electric trams within the borough has been made by a public company, but no definite action has yet been taken. The question of granting additional licenses for motor passenger cars came before a special meeting of the Town Council last week. After an animated discussion it was decided to grant a portion of the licenses applied for,

**New Engine Company.**—This company have opened works, under the style of Acton Hill Works (opposite tramcar depôt, Uxbridge-road), Acton, W., for the manufacture and repair of motorcars. The works cover 15,000 square feet, and are equipped with the latest tools. We are informed that the company will have on the road a 25-h.p. to 30-h.p. car of a distinctly novel arrangement.

**Railway Motor 'Buses.**—The proposals of the North-Eastern Railway Committee in regard to running motor 'buses are not deemed satisfactory by the Municipal Tramways Conference, which decided to hold a further meeting before the company's Bill comes before the House of Commons committee. The tramways owners stipulated that these motor 'buses shall only be used to act as feeders to the railways.

**Ardrossan (N.B.).**—At a meeting of the local committee of the County Council a letter was read from the promoters of the scheme for constructing a tramway line from Ardrossan to Stevenston to the effect that the scheme had now been formulated, the promoters expressing their intention of applying for a provisional order in November next. The proposed line is to start at a point between Ardrossan and West Kilbride, and to be continued through Ardrossan on to Stevenston.

**Sale-Altrincham.**—Some little difficulty has occurred in regard to the Northenden-road section of this proposed tramway, the Cheshire County Council stipulating for certain street widenings, while the Sale Urban District Council contend that the road is already as wide as the Board of Trade regulations. The matter has been referred to the Board for their views, both parties agreeing to abide by the decision. The lines would be leased to the Manchester Corporation for 42 years.

**Weston Clevedon Light Railways.**—Mr. Justice Swinfen Eady had before him on Saturday a petition for the appointment of a receiver of the Weston, Clevedon, and Portishead Light Railways Company. Counsel stated that an endeavour was being made by the company to carry out an arrangement whereby a reconstruction could be effected. If that arrangement was not come to, the petition would be proceeded with. His lordship directed the petition to stand over till Tuesday week.

**Proposed Ayrshire Tramway.**—At a meeting of Northern District Committee of Ayrshire County Council last week a communication from agents in Edinburgh was laid before the meeting with reference to the inauguration of a tramway system between Ardrossan and Stevenston. The scheme appears to have now taken definite shape, and the promoters propose to apply for a provisional order in November next. A meeting is to be arranged between the District Committee and the promoters with the view of coming to an agreement as to the route.

**Dalkeith.**—A communication has been received by the Town Council from the Edinburgh Suburban Electric Tramways, Limited, stating that the company feel indisposed to proceed with the scheme, so far as the burgh of Dalkeith is concerned, if the running of cars on Sundays is to be prohibited. The financial success of the undertaking, the letter states, would be extremely doubtful if only six days' running were to be allowed. The Council have decided to grant the concession sought as to Sunday cars, while certain minor matters in regard to the agreement have been remitted to committee.

**Cardiff.**—Mr. Arthur Ellis, tramways manager, has reported to the Tramways Committee that the receipts for April, compared with the corresponding month of last year, have increased by £276. Notwithstanding that during the month they had been running nearly eight fewer cars there had been an increase in the number of passengers of 14,506, while the tram miles run had been reduced by 14,949. There was also a decrease in the expenditure, which was £100 less. This had been achieved despite the fact that the loan charges were £336. 2s. 4d. The net increase for the month was £336. 8s. 5½d. Had the loan charges been the same as last year, the net increase would have been £712. The chairman remarked that this was exceedingly satisfactory, and the other members of the committee concurred.

**Glasgow.**—The enquiry into the application under the Private Legislation Procedure (Scotland) Act of the Corporation for, *inter alia*, power to construct a number of tramway extensions has been concluded. Certain sections were abandoned and other disallowed, as mentioned in our issue of last week, but several important routes have been sanctioned, the chief including those from Tollcross to Uddingston, Maryhill terminus to the city boundary, Great Western-road to Gairbraid-street, Nithsdale-road to Dumbreck-road, and one to Baillieston. Power has been given to run omnibuses as feeders to the existing lines, so as to test the advisability of extensions. The carriage of parcels up to 500lb. each was sanctioned, subject to the consent of the Renfrewshire County Council being obtained in respect of the lines in their area.

**Berlin Elevated Railway.**—The general annual meeting of the Elevated and Underground Railway at Berlin was held on the 11th inst., the chairman being ex-Minister of State Hobrecht, who gave details as to the development and expansion of the company. It was stated that the traffic, especially in the section from east to west, had increased in a most satisfactory manner, and traffics generally had been assisted by the demand for dwellings and business offices in the neighbourhood of the stations. The extension of the railway in the city of Charlottenburg was commenced during the past year. If the arrangement with Charlottenburg is ratified by the authorities, the construction of the line will be pushed on as quickly as possible, so that it may be opened in 1907. As to the extension in Berlin, negotiations are going on with the authorities in regard to the construction of the section from Potsdamer Platz to Spittelmarket, and the section from Spittelmarket to Alexander Platz. There is little doubt that these negotiations will end successfully, as all the inhabitants of Berlin are convinced that the "elevated" has become a necessity.

**Lambeth.**—The Borough Council last week considered the question of the electrification of the London and Southern tramway undertaking, which runs from Vauxhall to Norwood. Although the Council has already agreed to support the Bill of the company for the electrification of the system, the Financial Committee now recommend that £225,000 be contributed by Lambeth toward street widenings, in order that the London County Council might purchase and electrify the line. The London County Council declined to purchase unless Lambeth gave one-third of the cost of street widenings. An amendment was submitted that as the Council had already decided to support the company, it was inexpedient that they should give £225,000 in order that the London County Council could purchase and work the trams. Eventually the amendment was rejected, and the recommendation to give £225,000 was then carried by a majority of two.

**Wednesbury.**—A special meeting of the Town Council was convened for the 17th inst. to deal with a report from the General Purposes Committee as to a settlement of the tramway difficulty which has existed for several years. The actual terms on which a settlement has been arrived at between the South Staffordshire (Lessee) Company and the Town Council are shown by the resolutions which the Council will be asked to confirm. These provide that an agreement be entered into with the company for the purchase by the Corporation of the tramway undertaking, including the site of the depôt, workshops, offices, buildings, and the fixed and loose plant, etc.—but excluding the portion of the line running from James Bridge to Moxley—with the electrical equipment, for £23 920, and that application be made to the Local Government Board for consent to a loan of £29 000. A resolution also provides that the seal of the Corporation be fixed to a conveyance for the sale to the tramway (lessee) company of the site of the depôt, workshops, and offices, together with the buildings thereon, and the plant, etc., for £11,500, and that, on the completion of the sale, the proposed loan be proportionately reduced. One result of the settlement is likely to be an early resumption of the tramway service between Wednesbury and Darlaston.

**Lifeguards.**—An inquest was held at Liverpool last week upon Stamford Wilkes, who was killed by an electric tramcar, a question being raised as to the efficiency of the "plough" lifeguard attached to the front of the car. It was stated that the guard passed over the man as he lay on the track after falling from an outside seat on the car, and that he could not be got out till the car had been lifted, an operation which took 11 minutes. Mr. C. R. Bellamy, general manager of the tramways, said that after the accident he examined the lifeguard on the car, and found it was adjusted in the usual way, with a fixed clearance of 2¼in. from the railhead. He found it difficult to reconcile his knowledge of the plough guard with the suggestion that the body had passed beneath it. The Coroner: The fact remains that it did. Mr. Bellamy: This case stands out because of our immunity from accident in Liverpool compared with other places. I am convinced we have the best guard in use in Liverpool, and we have the best record. The Coroner: I know everything has been done to make it as perfect as possible. Last year 123 accidents occurred in which it was efficacious in sweeping the body aside. Mr. Bellamy said he had looked fully into the matter, and was not prepared to make any suggestion for the improvement of the guard. The Coroner remarked that he only mentioned the lifeguard in order that the public mind might be assured that everything was being done to make it as effective as possible. The jury found that death was accidental.

**Live Rail Dangers.**—The Board of Trade have issued Lieut.-Colonel Druitt's report on the fatal accident which befell Fireman Philip Allen near Manors Station, Newcastle, on the North-Eastern Railway, on March 18. He was found lying dead in the six-foot way between the up north and down Tynemouth lines, close to Argyle-street signal-box, having evidently been run over. In an explanatory introduction, Lieut.-Colonel Druitt states that near Argyle-street signal-box there are four passenger lines running approximately east and west. The four passenger lines and the connections between them are fitted for electric traction, but the sidings are not so fitted. The live rails are all protected throughout the length of the sidings by a wooden guard on each side of the rail extending to a height of about 2in. above it, but at the connections this protection can only be given on one side of the live rail, as otherwise it would prevent the shoe of the electric car passing from the live rail of the crossing to that of the passenger line. Lieut.-Colonel Druitt says: "It is impossible to say exactly how this fatal accident occurred, as no one apparently saw Allen from the time he was relieved from duty at 4.30 a.m. until his dead body was found at 5.45 a.m. With regard to men crossing from the south to the north yard while it is dark, the through road, being quite straight and free from any 'live rails,' is safe as far as coming in contact with such rails is concerned, but from a general point of view is not so safe I think as if men walked along the sidings to Manors Station, where there is a recognised crossing from the siding to the platform, and the men might be encouraged to use this crossing at all times."

**Burton.**—The report of the working of the Corporation tramways for a complete year—the previous report embodied only eight months—was issued last week, and is regarded with general satisfaction. The revenue totalled £17,950, the passengers numbered 3,878 269, the traffic receipts per car mile being 9·21d. The increased car mileage run, consequent upon the faster and improved service, is partly accountable for the reduction in the receipts per car mile, and the industrial depression in the town accounts for the small decrease in receipts compared with the correspondingly first eight months' working of the trams. The service has been speeded up since July, the average speed on all routes, including stoppages, now being 6·85

Digitized by Google

miles per hour. The gross revenue shows a surplus of income over expenditure of £5,160. 19s. 5d., of which £4 604. 0s. 7d. is absorbed by repayment of debt and interest, leaving a balance of £556. 18s. 10d., which has been carried to repairs and renewal fund. The total receipts amount to 9·49d. per car mile and the total operating charges to 6·76d. per car mile. A parcels delivery system was inaugurated Nov. 1 last; but, contrary to expectation, has met with scanty support so far. This traffic is slightly increasing, but no doubt when the advantages of the system are more understood it will considerably improve. The traffic from passengers' luggage and newspapers shows a satisfactory increase, the total number of parcels of all classes amounting to 39,639 for the year. Three cars were fitted with covers at the end of last year at a total expenditure, including fittings and all alterations to cars, of £84. 13s. each. The extra comfort of these has undoubtedly been appreciated by the public, and the takings on these cars have been increased by about ¾d. per car mile. The cars, overhead and track work, have been generally kept in good repair and maintenance. No serious accidents occurred.

**Belfast.**—At a meeting of the Tramways Committee a deputation of Ligoniel inhabitants was received, a request being put forward by them that the Ligoniel line should be extended to Wolfhill Mill. The deputation maintained that this would not only be a convenience to the people of the district, but it would also be advantageous to the tramway undertaking. The Lord Mayor asked several questions, and after the deputation had retired it was agreed that, as soon as the contract of Messrs. J. G. White and Co. had been completed, this matter should be taken up, and every effort made to meet the wishes of the people of Ligoniel. Another deputation requested that the extension to Greencastle should be completed at once. The town clerk read the clause in the Act of Parliament referring to this matter, and several questions were asked. When the deputation had retired some discussion ensued, and finally it was decided that Mr. Cutler, the city surveyor, should push forward the construction of this extension in every possible way so as to have it completed. The consideration of the by-laws and of the fares was postponed for a week, so as to get information as to the fares charged in other cities. At a subsequent meeting a deputation representing the National Telephone Company was received, a member of which stated that the decision arrived at by the committee, to the effect that all the overhead telephone wires must be removed in streets in which the electric tramcars ran, would be a most serious one for the company, as it would mean that they would have to find underground accommodation for the wires used by 1,000 subscribers. Eventually it was decided that the electrical engineer should consult with the town clerk upon the legal aspect. Mr. Nance presented a report in respect to the tramway on the Queen's road. In the discussion which ensued between the Lord Mayor and the manager, the latter stated that after deducting the working expenses the yearly profit would be about £400. It was considered advisable that the committee should wait some time in order to ascertain the mind of the Harbour Commissioners on this important matter. The Commissioners are apparently prepared to construct this line themselves if the Corporation will pay them a certain sum for working it.

**Edinburgh.**—At a meeting of the Town Council last week for the purpose of considering the electric tramway systems which three companies have submitted to the Council as suitable for the extensions which the Corporation have in view. The three systems under consideration are the Dolter, the Kingsland, and the "G. B." system. The representatives of the companies each in turn explained to the committee the character and distinguishing features of their system, all three being surface-contact systems. Each of the parties claimed that their system might be laid at moderate cost, and each was willing to give details, but the committee refrained from getting figures on that point, as their object in the first place is to determine as far as they are able which is the better system mechanically, and from the point of view of public convenience and safety. Prof Kennedy, the electrical adviser of the Corporation, was present, and questioned the representatives of the companies on points regarding which he thought information was desirable. It was explained that the Dolter system has been working for some years in Paris and on the outskirts of Dresden. The Kingsland system has not yet been in commercial operation except in the case of a short section in Dresden. The owners of the "G. B." system have an experimental line about one-fifth of a mile in length working at Ilford. The committee had already seen the model of the Dolter system, and on the day previous to the meeting they had an opportunity of witnessing a working model of the Kingsland in one of the rooms in the Synod Hall. All three companies have expressed their willingness to lay down their surface-contact system in Gilmore-place and to work it for a year, on condition that if the Corporation are satisfied with the line they should take it over. If they are not satisfied, the company are willing that the line should, in the absence of any other more suitable system, be converted to the overhead system. There is also the alternative offered to the Corporation that if the experimental line should in their opinion, prove a failure, the company selected should remove the system altogether. Prof. Kennedy will report to the committee at an early date. It has been suggested that Morrison-street, where the cable tramway rails have been laid but are not in use, might by arrangement be taken as a street where the Corporation and the public might see the different methods of electric traction in operation.

**London County Council.**—At the meeting of the Council on Tuesday the report of the Highways Committee recommending the immediate acquisition and electrification of the North Metropolitan tramways was adopted by 68 votes against 20. We have already given the substance of this report, which, in conjunction with that of the Finance Committee, goes into the subject with much thoroughness. The latter report agrees with that of the Highways Committee in stating that the electric traction clauses of the lease are inoperative, except through the co-operation of the company, and "it is difficult," they say, "to see what inducement the company would now have to co-operate with the Council. The work of reconstruction, and its attendant losses through interruption and dislocation of traffic would, even with the utmost expedition, probably extend throughout the whole of the remaining term of the lease, and it can hardly be expected that the company would willingly enter upon a work the benefit of which would inure to the Council after the end of the lease, while the losses would fall largely upon the company." They therefore agree that if electrification is to be proceeded with, the Council should have the lines in its possession. The committee remind the Council of the heavy expenditure on capital account during the next few years, and express a wish that the electrification of the northern tramways might have been postponed for a year or two longer, but the reasons against incurring further capital outlay are not so strong when that outlay is upon a remunerative service which it will greatly improve. The approximate figures regarding cost of reconstruction are: reconstruction and authorised extensions, £2 906,120; setting back kerbs, £15 208; extra cost if the whole is on the conduit system, £470.000; street widenings (restricted), £945,275—total, £4 336 603. Further street widenings which are considered to be desirable will cost £794 350. The total expenditure involved in the scheme for purchase and electrification would, therefore, appear to be about £4 773 000, which, however, may be reduced to the extent of £470,000 if half the lines are reconstructed for overhead instead of for conduit traction. To these figures of total cost must be added the estimated cost of the second portion of the Greenwich generating station, which must be commenced at once. This may be taken at about £400,000, making a total outlay in round figures of £5,200,000. The expenditure would take place chiefly in the four years 1906-7 to 1909-10, at the rate of about £1,500,000 per annum. The loss of receipts during reconstruction is estimated to amount to at least £1,000 a mile of single line. Discussing the financial effect of the electrification, the Finance Committee remark that the traffic receipts are estimated at 1s. per car mile, and working expenses, including capital and renewal charges in respect of the power station, at 7d. per car mile, showing an estimated profit of 5d. per car mile. The traffic on the tramways, when reconstructed, is estimated at 21,024 000 miles per annum, on the assumption that 640 cars will run on the average 90 miles a day throughout the year. On these estimates the figures will be: estimated receipts, £1 051,200; estimated working expenses, £613 200; estimated gross profit, £438,000. The reduction of fares either by the introduction of halfpenny fares or the lengthening of existing stages would inevitably reduce the receipts per mile, although it would in all probability at the same time increase the car mileage, and thus add to the working expenses. Regarding the estimated cost of renewal of truck, cars, equipment, etc., and interest and repayment charges on capital outlay, the interest and repayment charges are estimated to be £252 500. If the lines are worked by the conduit system throughout, the sum of £470 000 must be added to the debt, and this is represented by £35 250 by way of interest and repayment, exclusive of street widenings. The estimated financial results of reconstruction are: estimated surplus on working, £438,000; provisions for renewals, £87,600; deduct interest and repayment charges, £287,750—surplus, £62,650. Further charges against the surplus will include annual debt charge on street widenings of £16,400, and increasing the renewals provision to 1½d. per car mile, after the first few years £43,800, making a total of £60,200. The estimated result shown by the above figures cannot, the committee say, be considered as anything but a very narrow margin. Inasmuch, however, as the debt would be repaid on the instalment system, the debt charges would diminish every year by about £5 000, and this sum would be added annually to the surplus. They are most strongly of opinion that provision should be made out of any surplus for the more speedy repayment of so much of the old horse traction debt outstanding as may be said to represent "dead" capital. The report concluded with these words: "There are various factors in the solution of the traffic problem of London, the operation of which it is impossible to foresee, but which must have a bearing upon the financial results of the Council's tramways. We refer to the tube railways now in course of construction, representing a very large expenditure of capital, the probable electrification of suburban railways, and the newly-arrived motor omnibuses. These considerations, having regard to the comparatively small margin of surplus shown by the foregoing estimates, appear to us to point to the necessity of the strictest economy in capital expenditure, and of exercise of caution in dealing with proposals to lower fares or to increase the cost of working the service." After considering this report and that of the Highways Committee, the Council decided, as stated above, in favour of immediate purchase, the terms being: consideration for the unexpired 4½ years of the North Metropolitan Tramways Company, £121,000; and for plant, rolling-stock, etc., £315 000 (approximately). The Highways Committee recommended the purchase of four electrically-driven watering-cars at a cost of £2 500. The construction of a cross-over at the northern end of Upper Clapton-road has been completed. The receipts for the four weeks ending the 6th inst. totalled £55,074, against £42,800 last year.

## LIGHTING AND GENERAL.

**Kirkintilloch.**—The charge for current for electric lighting has been fixed at 5d. per unit.

**Woolwich.**—Sanction has been received to the borrowing of £6,500 for electric light purposes.

**Altrincham.**—The District Council are considering a scheme for an extension of the electric light for purposes of street-lighting in Sale.

**Stonehaven.**—An application from the National Telephone Company asking permission to erect poles on a footpath and also on a road has been refused.

Digitized by Google

**Ebbw Vale.**—An enquiry has been held into the application of the District Council for permission to borrow £9 654 for the purpose of installing a system of electric street-lighting.

**Underground Telegraphs.**—The Postmaster General will have £150 000 this year to complete the underground telegraph line from London to Glasgow, and to begin others from London to the east and west.

**Dundee.**—The National Telephone Company are making progress with their underground mains extensions in order to make provision for new subscribers and to include districts not embraced in the original scheme.

**Bexhill.**—The gross profits during the year from the municipal electric light undertaking amounted to £2,668, an increase of some £612 upon those of 1903. Sinking fund and interest, however, reached the total of £2,870.

**Paignton.**—Amended plans, specifications, and estimates from the electric lighting company, together with the agreement, and an application for power to borrow £18,500 for the necessary works, are to be sent to the Local Government Board.

**Hammersmith.**—The premises of 21 additional consumers, representing a maximum of 403 8-c.p. lamps, have been connected to the mains; six consumers have been disconnected. The present number of consumers taking current from the mains is 1,582.

**Glossop.**—An electrical exhibition has been held at the Victoria Hall in aid of the Wood's Hospital. The Mayor performed the opening ceremony. The arrangements were in the hands of the Urban Electric Supply Company's resident engineer, Mr. C. E. Knowles, A.M.I.C.E.

**East Ham.**—A special meeting of the Town Council will be held on the 23rd inst. to consider a resolution consenting to the opposition by the Council to Bills, including the East London and Lower Thames Electric Power, the Administrative County of London and District Electric Power Company, and the Charing Cross and Strand Electricity Supply Corporation, Limited, Bills.

**Stock Exchange.**—The Stock Exchange Committee have ordered the Charing Cross, West End, and City Electricity Supply Company's further issue of £70,000 4 per cent. debenture stock to be quoted in the official list. Application has been made to allow the British Westinghouse Electric Manufacturing Company's further issue of £400,000 4 per cent. mortgage debenture stock to be quoted in the official list.

**Langdon-Davies Motor Co.**—The old company has now been formally wound up, the existing company being a reconstruction of the old company. There have been small alterations in the Board, made when the company was reconstructed, Mr. F. B. O. Hawes, A.M.I.C.E., A.I.E.E., being now chairman and general manager. Messrs. W. Langdon-Davies and A. Soames are now the consulting engineers of the company, and not on the Board.

**Indian Contracts.**—Messrs. Lowdon Bros., electrical engineers, Dundee, are at present executing extensive orders for Calcutta. Yesterday the firm dispatched to India two 80 h.p. engines and dynamos, while within the past fortnight they have contracted to supply several jute mills with lighting plant, the new orders including four engines and dynamos, each of 100 h.p., with the necessary lamps, a 70 h.p. engine and dynamo, and a separate 100-h.p. dynamo, together with 2 300 lamps.—*Dundee Advertiser.*

**Electricity in Mines.**—Messrs. Evershed and Vignoles, Limited, of Acton-lane Works, Chiswick, W., inform us that they have been in communication with the Home Office on the subject of the new rules as far as they concern the continuous indication of insulation resistance. While acknowledging that the tests contemplated by clause 7, section 1, cannot be strictly carried out, the Home Office have stated that instruments made in accordance with Messrs. Evershed and Vignoles's suggestions will meet their requirements.

**Torquay.**—At the last meeting of the Town Council the opinion of Mr. Eve on the position of the authority in connection with the electric station was read. The Dolter Company had asked for a definite decision as to whether the Corporation would be prepared to let the company their electrical undertaking, or whether they would consent to their erecting their own generating station. They suggested a conference. It was decided to ask the Local Government Board to reconsider their recent decision, the Council being unable to withdraw its application for the loan.

**King's Lynn.**—The engineer, in his last report, states that during the month applications had been received for 154 additional lamps of 8 c.p. (or equivalent), making a total of 20,764 lamps and 515 consumers. The following figures are available: units generated, March, 1905, 41,760 (1904, 41,418); total units sold to private consumers (light and power) 20,553 (20 541); units sold at power rates, 8,910 (9 958); cost of fuel, stores, repairs, and wages at station, £126. 17s. 8d. (£120. 12s. 1d.); cost per unit generated, 0·7292d. (0 6988d.); wages of lamplighters and outside staff, £18. 16s. 9d. (£18. 16s. 3d.).

**London Gazette.**—The partnership between Cecil August Esmarch and James Mellanby Morrish, carrying on business as electrical engineers at Albert-road, Middlesbrough, has been dissolved by mutual consent. The first meeting in the estate of Harry John Salter, electrical engineer, 235, High Holborn, London, will be held at Bankruptcy-buildings, Carey-street, London, on May 22 at 12 noon. The British Electric Traction Company, Limited intend to apply to Parliament for additional provision to extend the time for the construction of certain tramroads authorised by the Wellingborough and District Tramways Act, 1900.

**Dry Battery Litigation.**—Some 18 months ago the trade was agitated by legal proceedings with regard to an alleged infringement of dry batteries. This action has now, in consequence of a recent decision in the House of Lords, been revived. The principal firms in the trade, however, contemplate resisting vigorously this renewed attack, and a preliminary meeting took place the other day. Our advertisement columns contain an invitation to join this movement; those interested in the matter should communicate with Mr. Walter Davenport, secretary to the Electrical Manufacturers' Association Incorporated), Ridler-place, Holland-street, Blackfriars, London, S.E.

**Southwark.**—The following motion was brought up at the last meeting of the Borough Council: "Inasmuch as the electric light system of the borough is extravagant, very inefficient, and costly, and has been a heavy burden to the rates, this Council take steps to obtain offers for the same with a view to selling the undertaking as a going concern." The Mayor ruled it out of order. In reply to a number of questions as to the loss or profit on the electric light undertaking, the Mayor said that he might feel it necessary to refuse to accept similar questions, especially at this juncture, when an enquiry was proceeding in the House of Lords on questions affecting electric lighting and where any information given in Southwark might be used generally against municipal undertakings. Anyhow the present questions might be left over for a few weeks.

**Cardiff.**—Mr. Arthur Ellis (borough electrical engineer and manager), in his last report, gives the number of consumers connected to the mains as 1,136, with a total equivalent of 131,022 8-c.p. lamps. The total for the corresponding period of last year was 110 341, there being now an increase of 19 per cent. in the total connections. The total number of units generated at the lighting station at Canton during the month was 115,668, and the total supplied from the Roath power station to the Hayes sub-station was 150,691, the combined alternating and direct current units making a total of 266 359, being an increase of 16 per cent. in the output over that of last year. The estimated revenue was as follows: revenue from street-lighting, £626. 7s.; revenue from private supply, £1,467. 12s. 10d.; making a total of £2,033. 19s. 10d., being an increase over the corresponding period of last month of 8 per cent.

**Electric Power Bills.**—Lord Camperdown's Committee of the House of Lords on the 11th and 12th inst. further considered various Electric Lighting and Supply Bills. After the promoters' case for the City of London Electric Lighting Company (Extension of Powers Bill) was closed, the committee decided to postpone for the present the hearing of the case against the Bill. The same course was pursued in the case of the Charing Cross and Strand Electricity Supply Corporation Bill. Part of the case for the Metropolitan Electric Supply Company, Limited, Various Powers Bill was heard, after which the committee adjourned till Monday, the 15th, when evidence was heard on both sides *re* North Metropolitan Electric Power Supply Company Bill. The committee reserved a decision, and, having heard the opening statement on the Central London Supply Bill, adjourned. On the 17th the case for the promoters of the County of London Electric Supply Company Bill was closed, evidence for the opposition was heard, and, after Mr. Balfour Browne's reply, the committee consulted in private and adjourned.

**Birkenhead.**—Last year's working of the Corporation's electricity undertaking gave the following financial results: 1904 5—capital expenditure at end of year, £118,171 (1903 4 £100 843); revenue from electricity supply, less allowance for bad debts, £12,049 (£10,459); revenue from meter rents and other sources, less depreciation on motors, £848 (£698); total revenue, £12 897 (£11,157); total costs, £4,727 (£4 373); gross profit, £8,169 (£6 784); percentage of gross profit to average capital, 7·46 per cent. (6 99 per cent.); interest on loans, less interest receivable, £3 307 (£2,964); sinking fund, £2,753 (£2,433); percentage of sinking fund to average capital, 2 51 per cent. (2·51 per cent.); financial result after providing for interest and sinking fund, £2,108 (£1 386). The number of lamps, etc., connected at end of year 1904 5 were equivalent to 66 574 8-c.p. lamps, as against 50 353 in 1903 4; the number of units sold were—private supply, 657 045 (566 255); public lighting, 102 376 (94,916)—total, 759 421 (661,171); the units sold per 8 c.p. lamp (connections made during the year averaged) were 12·99 (14·6): the maximum load on feeders was 652 kw. (556); the load factor was 13·29 per cent. (13·29 per cent.); the capacity of dynamos at end of year amounted to 1,375 kw. (1,050); the prices obtained averaged as follows—private supply, 4·08d. (4 05d.); public lighting, 1·70d. (1·86d.)—total supply, 3·76d. (3·79d.).

**Bermondsey.**—On Tuesday evening, at Bermondsey Council, the annual financial statement in connection with the electric light undertaking was presented. The total amount of loans obtained up to March 31, 1905, is £98,030, of which £487. 5s. 2d. has been repaid. The total expenditure on capital account is £105 793. 10s. 9½d., the overdraft in anticipation of losses being £7,651. 0s. 8½d. The revenue account shows the expenditure on the generation of electricity to be £4,032. 11s. 6d.; distribution, £4 497. 6s. 9d.; public lamps, £1 230. 3s.; management expenses and law charges, £1,135. 1s. 9½d.; the total being £7,711. 5s. 4¾d. The income is £12 015. 19s., leaving £4 271. 3s. 1¼d. to be carried to net revenue account, and £33. 10s. 6d. to be set aside for bad debts. Interest on mortgage debts (£2,801. 2s. 2d.), instalments of principal (£362. 19s. 11d.) and payment of to reserve fund (£499 5s. 6d.) absorb £3 663. 7s. 7d. of the £4,271 3s. 1¼d., and £1,000 is added to the reserve fund. The general balance sheet shows the gross liabilities to be £111 265. 16s. 5½d., including overdrafts on capital and revenue accounts of £9,358. 12s. 9½d. The electricity generated from March 31, 1904, to March 31, 1905, was 1,039,503 Board of Trade units, 282 185 units being supplied to public lamps and 649,914 to private consumers by meter. Mr. L. A. Laws, in the employ of the Lincoln Corporation, was appointed mains superintendent. Testimonials were granted to Mr. Wallis, late mains foreman, and to Mr. W. H. Vincent, M.I.E.E., late electrical engineer. Three hundred and sixty-nine equivalent 8-c.p. lamps for private lighting have been applied for during the past month, making 36,368 up to date; or including street-lighting, 39,354. This is 6,710 in excess of the capacity of the present plant. The Council resolved to petition against the Supply of Electricity Bill,

Digitized by Google

**Beckenham.**—The Urban District Council have decided to ask the Board of Trade as to the necessity for a provisional order applying the powers of the Beckenham electric lighting order to the Crystal Palace district when taken over. With regard to a suggestion for supplying the Crystal Palace Company with electric current from the Beckenham electric lighting station, it has been resolved, owing to the doubt as to the Council's power of affording a supply under the required circumstances, not to entertain the proposal further.

**Finchley.**—The transfer of the Finchley Electric Light Company's mains and the goodwill of the business was completed on April 14 The electric lighting accounts for the year ended March 31, 1905, show a general expenditure of £2 620, a revenue of £3,922, making a net revenue of £1 300. Interest and sinking fund absorbed £1,072, leaving a balance of £228, which is to be transferred to a reserve fund account. Councillor Todd, in moving the adoption of the accounts, said that, on behalf of the committee and the Council, he ought to congratulate the electrical engineer on the results he had achieved. The recommendation was unanimously approved.

**Batley.**—The electric light has been installed at the Batley and District Hospital at the cost of Mr. Charles Robinson. Messrs. Spivey and Jubb have been the contractors for the installation, and have put in over 90 lamps. The fittings throughout are of steel bronze. All the wards are lighted in the centre, the largest wards having four lights and the smaller ones two. The corridors, staircases, board-rooms, and the rooms used by the staff are also well lighted. At the opening last week an X-ray apparatus was received from an anonymous donor, and the medical staff have subscribed 100 guineas towards an enlargement of the hospital, so that some suitable place can be provided for the installation of the apparatus.

**Hove.**—The Council have confirmed the following proceedings of the Lighting Committee: The thirteenth report and statement of accounts of the electric lighting company for the year ended December, being produced before this committee, the town clerk was directed to ask the company to explain why the accounts had been published before being audited on behalf of the Council as provided for in the deed of transfer. The Council are recommended to authorise the committee to take such steps as they might be advised, as provided for in the deed of transfer of Dec. 8 1892, to obtain an alteration in the prices or charges made by the company, for electric energy within their area of supply. It was stated that Aldrington would be supplied with electric light within three months.

**Darlington.**—At the last meeting of the Electric Lighting and Tramways Committee, Mr. Lunn, manager of the works, submitted his annual report, which showed an increased revenue of £957, or 19 per cent. compared with the previous year, notwithstanding that the price per unit has been reduced by ½d. The report states that there had been a substantial reduction in the cost of production, and there had been generated with the same plant, owing principally to the increased supply for the tramways and otherwise, between 2½ and 3 times as many units as in the previous year. The net profit for last year, in spite of the large interest and sinking fund charges, was nearly £1,500, and it was suggested that the price per unit for lighting be reduced from 4½d. to 4d. For power purposes reductions from 2d. and 1½d. to 1½d. and 1¼d.—that is, 1½d per unit for the first 500 units per quarter and 1¼d. per unit for all over that—were proposed The report was adopted.

**Houghton-le-Spring.**—As a result of a difference between the postal authorities and the Urban District Council, the district has, says the *Yorkshire Post*, been put in a state of isolation as far as telegraphic communication is concerned. Apprehension has been felt by the postal authorities at the proximity to the telegraph wires of the overhead cables erected by the Sunderland District Tramways Company, which has intimated its intention to switch on the current during the present week. They accordingly asked leave of the Council to shift the poles and wires to the other side of the road, but consent was refused, the Council urging that the poles should be erected on private land. To this the postal authorities demurred, stating that the revenue from the local telegraph service would not justify the expense which would be involved. As no agreement has been come to, the telegraph service has been suspended. It is hoped that the matter will be arranged satisfactorily at a conference which has been fixed to take place between the Council and the sectional telegraph engineers.

**St. Marylebone.**—"A Marylebone Consumer" writes to the *Times*, under date May 14, as follows: "The open trough in Montague-place, of which a resident complains, is a trifle compared with the increased voltage which is now being pressed on the consumers. The alteration from 100 to 240 volts will entail a change of every lamp and fitting in the borough. The municipality will change the lamps without cost to the users, but the expense will be enormous, and the whole will have to be paid out of the rates! It is a gift with one hand, while the cost is taken with the other. Moreover, the ratepayers who do not use electricity will have to pay their share of the extravagance. No one seems to wish for the change. Many intend to refuse their consent, which, to their surprise, is asked at the last moment. If they decline to give it, the question is to be decided by an arbitrator of the Board of Trade. What practical decision he can give no one knows. Another important question is also unknown—the influence the increased volt-age will have on assurance policies. Surely the original acquisition of the electric company was muddle enough without this intensification of a bad business. It is to be hoped that those who are now satisfied with their current will refuse to consent to the change."

**Islington.**—The Council on Friday decided to obtain expert's opinion on the extensions of generating plant, estimated at £15,000. At to-night's meeting it will be proposed that two mains extensions be made at a cost of £150 and £80 respectively, and the Lighting Committee will report as follows: "In proceeding to give effect to the resolutions of the Council of April 6 and 14 last authorising us to instal arc lighting in the Newington Green district and in Stroud Green-road, we have carefully considered the type of lamp to be adopted and have tested with satisfactory results the Excello flame lamp, which is manufactured by the Union Electric Company, Limited. We have also had under consideration the desirability of substituting lamps of this make for the ordinary arc lamps erected at certain spots in boundary roads, and are of opinion that it would be advantageous to do so. We recommend that a contract under the seal of the Council be entered into with the Union Electric Company, Limited, for the supply of 42 Excello flame lamps." Referring to the purchase of six mechanical stokers, the committee say that satisfactory tests have been made at the electric lighting station with the mechanical stoker of the chain-grate type manufactured by Messrs. Babcock and Wilcox, and they recommend that three sets of chain-grate mechanical stokers be at once ordered from Messrs. Babcock and Wilcox, subject to their agreeing that the Council shall not be liable for any payment therefor until the sanction to the loan has been received from the London County Council.

**Electrical Mining Machinery.**—Messrs. Ernest Scott and Mountain, Limited, of Newcastle-on-Tyne, and the Close Works, Gateshead, have recently received a contract from the Butterley Coal Company, of Derby, for their Kirkby Colliery in Nottinghamshire, the installation consisting of two horizontal compound-condensing steam-engines, each of 450 h.p., driving on to two slow-speed three-phase generators, each of 310 kw. capacity. This plant will supply current to four endless-rope haulage gears placed underground at distances varying from 20 yards to 650 yards from the shaft bottom, the haulage gears bringing the coal from long distances in bye. The haulage gears are each driven by three-phase motors of Scott and Mountain's latest design, each motor being capable of giving 100 effective horse-power, and the haulage gears are provided with the firm's special type of friction clutch and friction brakes. A complete system of telephones is also being arranged between each haulage room and the main power station at bank. One generating set is of sufficient size to drive the four haulage gears, and the second set is used as a stand-by, and for driving pumping machinery and other machinery at the surface. The Wigan Coal and Iron Company, Limited have also decided to increase their electrical plant at the Manton Colliery, and have placed this work in the hands of Messrs. Scott and Mountain, who recently carried out an installation for pumping and hauling machinery at the Wigan Company's Sovereign pit. The plant at the Manton pit will consist of three compound horizontal steam-engines and crankshaft alternators, each of 550 h.p. In addition to this, there is a continuous-current generator capable of supplying 2 500 lights, which are being installed for lighting at the surface and underground and also the houses of the officials and workmen. The pumping machinery at Manton Colliery consists of five sets of Scott and Mountain's well-known mining pumps, each set being capable of delivering up to 1 000 gallons per minute, and is probably one of the largest in the United Kingdom. We also understand that Messrs. Scott and Mountain have a considerable number of other important contracts in hand, including installations of mining machinery for the Mickley Coal Company, Ashing Coal Company, Harton Coal Company, North Navigation Collieries Company, Swalwell Colliery Company, Shelton Steel and Iron Company, Consett Iron Company, Bell Bros., Limited, Cammell, Laird, and Co., and others, and are extremely busy in their new works at Gateshead, which have now been completed, which gives the firm increased facilities for producing all classes of engineering work and electrical machinery.

**Kingston-on-Thames.**—The borough electrical engineer (Mr. J. E. Edgcome) in his eleventh annual report on the working of the Corporation electricity undertaking for the year ending March 31, 1905, says an extension has been added to the engine-house, consisting of two bays in which the new generating plant has been installed. The three-crank, triple-expansion, high-speed, enclosed engine of 350 h.p. direct coupled to a single-phase alternator of 200 kw. capacity, mentioned in the last report, has been delivered and erected, but not yet taken over from the contractors. A large number of extensions of the distributing mains have been made for the purpose of connecting up consumers. Transformer pillars and section pillars containing disconnecting gear have been erected in various streets. These pillars, which are designed for dividing up the mains throughout the borough into sections, says Mr. Edgcome, are proving a convenient and readily accessible means of controlling the supply throughout the district from various points, and, unlike the underground sub-stations, are not subject to disturbance from water during floods. He also reported a satisfactory increase in the use of electric motors in the borough for driving printing, cutting, and folding machines, hair-brushing machinery, aerated water machinery, organ blowing, boot stitching, dental drills, and ventilating fans, etc. Current for motors and heating apparatus can be supplied through a separate meter at the reduced rate of 3d. per unit, the rental for this extra meter being 6d. per quarter. Small motors for driving sewing machines can be purchased for about £3, the current taken by this type of motor costing about ¼d. per hour. With regard to the question of electric side street lighting still under consideration, experiments were being carried out with a view to obtaining the best results. The working of the Corporation's electricity undertaking for the last 12 months shows a profit of £1,074 owing partly to an increase in the revenue receipts amounting to £430 and partly to the reduction in the cost of generation and distribution amounting to £641, the latter feature being particularly satisfactory. The number of consumers has increased from 630 to 746, an increase of 116. The number of lamps, motors, and other apparatus (in terms of 8 c.p. lamps) applied for and connected has increased from 28,603 to 33,709, an increase of 5,106. This increase in the number of consumers is very satisfactory, and is the largest increase during any 12 months since the works commenced running. The total capital expenditure to March 31, 1905, amounted to £292,205. The amount of capital expended during the year was £5,736, the amount of capital repaid being £2,658, leaving a balance

Digitized by Google

of outstanding capital expenditure to March 31, 1905, of £75,860, a total sum of £16,344 having been paid off the capital account. The total works expenditure has been decreased by £447 from £5 046 to £4,599, whilst the total revenue has increased by £430 from £10,002 to £10,432, a net increase of revenue over expenditure of £877, notwithstanding the rebate obtained by the majority of the consumers under the new system of charging. The average cost of fuel per unit sold has been reduced from 1·157d. to ·933d. The engineer states that the adoption of the demand indicator system, with charges of 7d. and 3d. per unit, had in almost every instance considerably decreased the cost of current to private house consumers, and especially to hotels and public-houses. The advantage generally to consumers on the circuit was indicated by the year's working, as a comparison of the total receipts from all classes of consumer showed that owing to the adoption of the demand indicator system with rates of 7d. and 3d., they had benefited by over £600 compared to the amount which they would have paid for the same current under the former flat rate of 6d. per unit. Mr. Edgcome finds that the Corporation's system of deferred payment wiring being now more widely known, an increasing number of consumers are availing themselves of this method of wiring their premises. The work is done on the following plan: The Corporation pay the contractor the cost of the work, such amount being refunded by the householder by means of deferred payments over a period not exceeding five years. A fee of 5 per cent. is charged by the Corporation for preparing the specification and superintending the work, interest at the rate of 5 per cent. per annum being charged each quarter on the outstanding balance. A number of consumers, although not wishing to avail themselves of this opportunity of spreading the payments over a number of years, have had their houses wired under this system in order that the work might be carried out to the specification and under the superintendence of the Corporation, and upon completion of the installation have paid the whole cost of the same, together with the Corporation's fee of 5 per cent. for superintendence, instead of dividing the payments over a period of years. Ten lamps with simple fittings can be installed for from £7 to £8. The gross profits on the works, after paying all charges, exclusive of payment of interest and repayment of capital, has increased from £4,955 to £5,832. There is a surplus after payment of interest amounting to £3,732, and after repayment of capital there still remains, as above stated, a surplus of £1,074, a very satisfactory result, showing that the era of prosperity of the undertaking, which commenced in the previous year, has been more than maintained during the past 12 months. The total capital expenditure sanctioned by the Local Government Board is £99,860, of which £19,654 was borrowed at 2¾ per cent., and the rest at prices varying from 3¼ to 4 per cent. The amount of electricity supplied to private consumers was 414,775 units, which brought in a revenue of £8,747. 13s. 1d., while for the 112,358 units supplied for public lighting the income was £1,586. 16s. 10d., the revenue per unit being 4·749d., which is the lowest price of any given in the table printed with the report, last year's figure (5·211d.) being the highest.

## PROVISIONAL PATENTS, 1905.

MAY 8.

**9649. Improved electric railway signalling system.** Percy Richard Julius Willis, Fife House, Kingston-on-Thames. (John D. Gordon, United States.)

**9655. Improvements in dynamo construction.** Henry Leitner and Richard Norman Lucas, Lynton, Dartnell Park, Byfleet, Surrey.

**9657. Improvements in and relating to electric accumulators.** Paul Alfred Gouin, 60, Queen Victoria-street, London. (Date applied for under Patents Act, 1901, May 9, 1904, being date of application in France.) (Complete specification.)

**9675. Improved electric worm reducing gear and automatic brake connected therewith.** Rowland George Harman, 10, Westmoreland-buildings, Aldersgate-street, London.

**9677. A new or improved connector for electrical conductors.** Edward Wilmer Hill, Norfolk House, Norfolk-street, Strand.

**9685. Improvements in electrical cables.** Henry Edmunds and Philip Dawson, 47, Lincoln's-inn-fields, London.

**9702. Improved field telephone and telegraph apparatus.** Patrick Joseph Kenny, 322, High Holborn, London. (Edward Molyneux, India.) (Complete specification.)

MAY 9.

**9708. Improved process for the electro-deposition of iron.** Sherard Cowper-Coles, Grosvenor Mansions, Victoria-street, Westminster, London.

**9739. Improvements in apparatus for controlling the supply of energy from alternating-current generators to alternating-current motors.** Arthur Pemberton Wood, 34, Castle-street, Liverpool.

**9746. An attachable and detachable light reflecting and diffusing device for electric and other lamps.** Charles Hindle, 30, Liverpool-street, King's Cross, London.

**9783. Improved construction of electric arc lamp.** Hermann Diamant and Andrea Chiesa, 173, Fleet-street, London.

**9794. Improved apparatus for automatically regulating the potential in electric circuits.** Joseph Kloppenstein, 11, Southampton-buildings, Chancery-lane, London.

**9797. Improvement in the method of electrically exploding the charges in the cylinders of explosion engines.** Harry Conduit, 8, Townshend-terrace, Sheen-road, Richmond, Surrey.

MAY 10.

**9815. Improvements in appliances for use in connection with the electric ignition systems for internal-combustion engines.** Charles Thomas Brock Sangster, 24, Temple-row, Birmingham.

**9837. Improvements in apparatus for compounding synchronous alternating-current machines.** Bruce Peebles and Co., Limited, and Jens Lassen La Cour, 34, Castle-street, Liverpool. (Complete specification.)

**9838. Improvements in multiple-unit controlling apparatus for electrically-propelled trains and the like.** Bruce Peebles and Co., Limited, and Jens Lassen La Cour, 34, Castle-street, Liverpool.

**9839. Improved means for the regulation of speed of compensated single-phase motors.** Bruce Peebles and Co., Limited, and Jens Lassen La Cour, 34, Castle-street, Liverpool. (Complete specification.)

**9865. Improvements in electric cables or conductors.** Allan Berlin, 7, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents Act, 1901, May 10, 1904, being date of application in Sweden.) (Complete specification.)

**9884. Improvements in main distributors for telephone exchanges.** Franklin Wise Howorth, 46, Lincoln's-inn-fields, London. (The Deutsche Telephonwerke R. Stock und Co. G. m. b. H., Germany.) (Complete specification.)

**9887. Improvements in and relating to the electrical driving of printing presses, calender rolls, and the like.** The British Thomson-Houston Company, Limited, and George Matthews Brown, 83, Cannon-street, London.

**9890. Magneto-electric igniter for explosion motors.** Leberecht Kootz, 40, Chancery-lane, London.

MAY 11.

**9892. Improvements of apparatus for regulating electric repulsion motors and similar purposes.** Edwin Freund, 39, Victoria-street, London.

**9901. A primary battery.** Sydney Robert Richardson, 45, Godwin-road, Cliftonville, Margate.

**9908. Improvements in connectors for electrical conductors.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

**9940. Improvements in the regulation of electric circuits subject to rapidly-fluctuating loads.** William Armistead and Max James Eccles Tilney, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

**9949. An improved telegraph key or "tapper."** Joseph Lancelot Addison, 70, Chancery-lane, London.

**9966. Improvements relating to electric group time fuses.** Henry Harris Lake, 7, Southampton-buildings, Chancery-lane, London. (The Firm Fabrik Elektrischer Zünder G. m. b. H., Germany.) (Complete specification.)

**9973. Improvements in electric controlling apparatus.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

MAY 12.

**9974. Improvements relating to oil, gas, vapour, steam, compressed-air, and hydraulic motors for steamships, electricity works, and road vehicles, and general work.** George Sellers and William Smith, care of the Caledonian Engineering and Shipbuilding Company, Preston.

**9991. Improvements in electric switches.** The Electric Ignition Company, Limited, and Frederick Harold Hall, 24, Temple-row, Birmingham. (Complete specification.)

**9993. A safety guard for the live rail of electric traction railways.** Alexander Swanson, Oathkin-avenue, Rutherglen, near Glasgow.

**10009. Improvements in magneto ignition devices for internal-combustion engines and the like.** Edward Russell Clarke, 35, Leinster-gardens, Hyde Park, London.

**10016. Improvements in electric meters.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

**10017. Improvements relating to the control of electric motors.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

**10047. Improvements in electric cables.** Willoughby Statham Smith and William Puddicombe Granville, 24, Southampton-buildings, Chancery-lane, London. (Complete specification.)

**10051. Improvements in brush-holders.** George Croydon Marks, 18, Southampton-buildings, Chancery-lane, London. (Abbot Augustus Low, United States.) (Complete specification.)

MAY 13.

**10067. Improvements in and relating to the treating of patients by static, galvanic, or like electrical currents.** Gerald Joseph Macaura, Sunbridge-chambers, Bradford, Yorks. (Complete specification.)

**10100. Improvements relating to overhead current collectors for electric railways and tramways.** Paul Platte, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents Act, 1901, May 14, 1904, being date of application in Germany.) (Complete specification.)

Digitized by Google

**10085. Improvements in the ventilating arrangements of dynamo-electric generators and motors.** Siemens Bros. and Co., Limited, Queen Anne's-chambers, Broadway, Westminster, London. (Messrs. Siemens Schuckertwerke G. m. b. H., Germany.) (Complete specification.)

**10097. Improvements in receivers for electric waves.** Johann Christian Schäfer, 3, Upper Vernon-street, London. (Date applied for under Patents Act, 1901, May 18, 1904, being date of application in Germany.) (Complete specification.)

**10111. Improvements in and relating to electric conductors.** Stanislaus Berger, 7, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents Act, 1901, May 14, 1904, being date of application in Germany.) (Complete specification.)

**10112. Improved insulating base for electric switches, plugs, pushes, and the like.** The General Contracts Company, Limited, and Joseph Gordon Salamon, 149, Strand, London.

**10118. Improvements in improved system of electric train-lighting.** Henry Leitner and Richard Norman Lucas, 4, South-street, Finsbury, London.

**10119. Improvements in electric insulating materials.** William Kennedy-Laurie Dickson, 64, Strand, London.

## COMPLETE SPECIFICATIONS ACCEPTED.

*To be published June 1.*

1904.

**8227. Alternating-current motors.** Zani.

**10457. Alternating-current electric motors.** British Thomson-Houston Company, Limited. (General Electric Company.)

**10656. Enclosed fuses for electrical installations.** Fellenberg.

**10711. Motor vehicle for agricultural purposes, applicable also for extinguishing fires, watering gardens, generating electric light, and other purposes.** Fröle.

**10722. Reverse-current electric circuit breakers.** Andrews.

**10794. Electrolytic apparatus.** Blackmore and Byrnes.

**11288. Electric accumulator electrodes or plates.** Ricks.

**11917. Process for obtaining producer-gas and electrical energy from peat.** Warburton.

**12333. High-tension electric switches.** British Thomson-Houston Company, Limited. (Allgemeine Elektricitäts-Ges.)

**12607. Combined electric lampholder and candle-nozzle.** Tiffin.

**13264. Continuous current electric motors and generators.** Torda.

**13643. Signals in telephonic exchange.** Oppenheimer. (Act.-Ges. Mix und Genest.)

**13947. Construction of electric tumbler switch.** Smith.

**15118. Dynamo-electric machines.** British Thomson-Houston Company, Limited. (General Electric Company.)

**15267. Electric light fittings.** Irving.

**15300. Electric transformers.** British Thomson-Houston Company, Limited. (General Electric Company.)

**15465. Hoisting and similar apparatus.** British Thomson-Houston Company, Limited. (General Electric Company.)

**15466. Air-brake systems and valves therefor.** British Thomson-Houston Company, Limited. (General Electric Company.)

**15634. Systems of electrical distribution and apparatus therefor.** Ferguson. (Date applied for under International Convention, July 13, 1903.)

**25641. Space telegraphy.** Stone. (Date applied for under International Convention, Nov. 25, 1903.)

**28968. Series commutator motors for single-phase alternating current.** Maschinenfabrik Oerlikon. (Date applied for under International Convention, Feb. 29, 1904.)

1905.

**3280. Devices for exerting an electromagnetic influence upon the arcs of electric arc lamps.** Carbone.

**3442. Gloves for electric insulation purposes.** Weilbier.

**3511. Devices for preventing the overcharging of electric cables.** Land und Seekabelwerke Akt.-Ges. (Date applied for under International Convention, March 31, 1904.)

**6286. Attaching electric insulators to tubular or like arms or brackets.** Siemens Bros. and Co., Limited, and Perry.

## NOTES.

**Tramways and Light Railways Association.**—The *Official Circular* for May contains the discussion on Mr. Parish's paper on "Friction as Affected by Lubrication," and an abstract of the measure to continue and amend the Light Railways Act, 1896.

**Opening Streets.**—A conference of representatives of the City Corporation, the Westminster City Council, and metropolitan borough councils was held at Westminster on Tuesday, when a resolution was passed urging the Government to introduce a Bill to give the highway authorities greater power to prevent the constant opening of public streets by the Postmaster-General and electric light and other companies.

**Faraday Society.**—The issue dated May of the society's *Transactions* contains Mr. J. G. A. Rhodin's paper on "Mass Analyses of Muntz's Metal by Electrolysis, and some Notes on the Electrolytic Properties of this Alloy"; Mr. R. B. Denison's paper on the "Equilibrium between Sodium and Magnesium Sulphates"; Mr. F. W. Harbord's paper on "Recent Developments in Electric Smelting in Connection with Iron and Steel"; Mr. A. H. Hiorns's paper on "Alloys of Copper and Bismuth"; and the first part of Messrs. R. S. Hutton's and W. H. Patterson's paper on "Electrically-Heated Carbon Tube Furnaces."

**New Publications.**—Messrs. Crosby Lockwood and Son will be shortly publishing a work on "Modern Lightning Conductors," which is likely to contain much of interest to all who wish to study the question of protecting buildings against damage by lightning. The author, Mr. Killingworth Hedges, C.E., was the honorary secretary of the Lightning Research Committee, whose report has just been issued, and in the new volume, besides illustrating many of the examples of lightning strokes furnished by the committee's observers, he describes the best methods for carrying out the suggestions contained in their report.

**The Liege Exhibition.**—The Liége International Exhibition has been opened under the auspices of King Leopold. The British section, under the direction of Mr. Imré Kiralfy, who accepted the honorary commissariat a few weeks ago, presents an animated picture of British industry and art, and as new applications from representative British firms are coming in, the few empty spaces in the section are being rapidly filled. Besides the United Kingdom, Canada, with a palatial building, forms a great centre of attraction. The King of Belgium has intimated to the British Commissioner his intention to make a special visit to the British section early next month.

**Milan Exhibition.**—It is reported that the Italian delegates who have been sent to England by the executive committee of the Milan International Exhibition are now in London. They have been presented to Lord Lansdowne by the Italian Chargé d'Affaires. The exhibition, which is the first international exhibition ever organised in Italy, will be held to celebrate the inauguration of the new Simplon Pass, and will be opened in Milan next April. It is under the patronage of the King of Italy, and will receive financial support from the Government. Italy, France, Austria-Hungary, Germany, Switzerland, Russia, Portugal, Spain, Belgium, the United States, and Japan are expected to participate officially.

**Birmingham Section.**—The report of the committee for the session 1904-5 states that seven general meetings were held, and the parent Institution has decided to include most of the papers in the *Journal*. The Institution has also decided to award a premium of £10 to Messrs. D. K. Morris and J. K. Catterson-Smith for their paper on "Some Uses of the Oscillograph," read during the previous session. The membership, all grades, has increased from 258 to 293. The chairman for the session 1905-6 is Mr. R. Threlfall, F.R.S., and the vice-chairman Mr. R. A. Chattock. Members are invited to submit papers in time to enable the committee to draw up a complete programme before the first meeting in November. It is not necessary that all papers should be sufficiently original for inclusion in the *Journal* so long as they are calculated to promote useful discussions.

**London County Council Combined Tickets.**—At Tuesday's meeting of the Council the Highways Committee recommended that circular tickets should be issued at the price of 5d., entitling the holder to travel by steamboat from Westminster Pier to Greenwich Pier, with the option of returning by tram to any of the London termini. The single tram fare from Greenwich to any of the termini is 3d., but it is proposed that the inclusive fare of 5d. shall be divided equally between the two departments for each passenger returning by tram, as the arrangement is likely to lead to increased tram traffic. It is proposed that, in the first place, the system shall be for one year, in order to see how the experiment works. The Council have deferred their decision. The suggested arrangement seems likely to prove a convenience to the public and a useful source of revenue to the tramway department.

**Optical Convention.**—This convention, regarding which we have given some particulars in previous issues, opens at the Northampton Institute on Tuesday next, and will continue until the end of the week. The president is Dr. R. T. Glazebrook, and sectional meetings will be presided over by the Earl of Rosse, Lord Blythswood, and Sir W. Adney. Such scientists as Lords Kelvin and Rayleigh, Profs. S. P. Thompson, Poynting, and Schuster, and Sir Howard Grubb are also lending their support to the movement. In his inaugural address the president will describe the objects and scope of the convention, and give a short account of the history of optical theory, with special reference to its application in practice. This will be followed during the convention by a number of instructive lectures and demonstrations. A comprehensive catalogue has been compiled giving descriptions of the instruments included in the various classes and other information.

**Rotating Diaphragm.**—At the recent meeting of the American Electro-Chemical Society, Prof. W. D. Bancroft presented a paper on "A Rotating Diaphragm," of which an abstract appears in the *Electrical World* of New York. The author stated that if in an acidulated copper sulphate solution a cylindrical graphite rod is interposed between two copper electrodes, copper will be deposited on one side and oxygen developed on the other side of the graphite rod, if the impressed voltage is high enough. After this has been done the graphite cylinder may be revolved through 180deg., so that the precipitated copper side will now face the cathode. The copper will then dissolve and the graphite cylinder will behave like a reversible intermediate electrode. Instead of reversing the graphite diaphragm repeatedly through 180deg., it is possible to revolve it rapidly. In this case it will also behave like an ideally reversible electrode. Experiments show that no visible amount of copper precipitates on such a rotating electrode, although a considerable proportion of the total current flows through the electrode.

**Municipal Enterprise.**—The Ipswich Corporation electric supply department has issued a businesslike collection of literature emphasising the advantages of electricity for power and lighting. In connection with the former it is pointed out that industrial users of power are

Digitized by Google

almost invariably the gainers by taking a supply from a large central station, on account of such stations being designed to yield the maximum efficiency and being under the control of a highly-trained staff. Regarding lighting, the pamphlets point out its great hygienic advantages in the home, and particularly in the nursery, while the attractiveness of an electrically-lighted shop window is duly enforced upon the minds of such consumers. Carefully worked out particulars are given as to the relative cost of current for various types of lamp, with information as to the special features of the different kinds. There are also hints on wiring houses for electric lighting, and some remarks upon electric ventilation. The various pamphlets are composed in lucid language, and their judicious dissemination should see a material increase in the department's load-factor.

**The Light Railways Act.**—A Bill to continue and amend the Light Railways Act, 1896, has been presented to the House of Commons by Mr. Gerald Balfour, supported by Mr. Bonar Law. The measure further provides that if any order under the principal Act is not confirmed by the Board of Trade on the ground that the proposals of the promoters ought to be submitted to Parliament in pursuance of Sub-Section 3 of Section 9 of the principal Act, the Board may submit the proposal to Parliament by bringing in a Bill for the confirmation of the order. This sub-section provides that if, on account of the magnitude of a proposal or other special reason, the Board consider that it ought to be submitted to Parliament, they shall not confirm such order. On bringing in such Bills for the confirmation of orders, the Board shall make a special report to Parliament. If, while a Bill confirming any such order is pending before Parliament, a petition is presented against the order, the matter may be referred to a select committee, or to a joint committee, the petitioner being allowed to appear and oppose as in the case of private Bills. The length of lines authorised as light railways up to the present date is 1,567 miles, and 429 miles have been constructed and opened for traffic.

**Egypt.**—Messrs. W. P. Thompson and Co., patent agents, Liverpool, notify that by Khedivial decree, and with the consent of the 14 Governments who, by the treaty of 1876, guarantee the independence and ex-territoriality of the International Courts of Justice in Egypt (commonly called the "Mixed Tribunals), the English language becomes as from 18th inst. official in such courts. This is one of the results of Lord Cromer's 20 years of unobtrusive but strenuous administration. Hitherto, French and Arabic have been the only official languages, and hence have been used exclusively in the courts, on the railways, and in Government departments generally. In the great prosperity of Egypt, and its expansion and development under British rule as a mining and manufacturing country, the protection of patents and trade marks there has taken a prominent part; but even in this department, though a very large portion of the trade is in British ships, the patents and trade marks have till now been registered only in the French language. Messrs. Thompson and Co. remark that, notwithstanding this, the business of protecting inventions has assumed large proportions, and their Cairo and Khartoum agents report themselves as overwhelmed with work. Their agents add: "Far too little of this is from England, though it would be well if British manufacturers would more generally register their marks here, the Act in itself forming a good advertisement for their products and being calculated to lead to enquiries for their goods." Until comparatively recently Egypt was a happy hunting ground for forgers of trade marks, and even now there is a large business one in imitating English marks, as no action can be brought for infringement until a mark is registered in the country, the same state of affairs prevailing in the Soudan.

**Lighting New York.**—A Bill has been passed by the New York State Senate creating a commission of three members with authority to regulate the price of gas and electric light and power, and providing for the supervision of such undertakings. The commissioners will have power to investigate the quality of gas supplied and the operations of persons or municipalities in supplying gas and electricity for light, heat, and power, and may order such improvements as will best promote public interests, preserve the public health, and protect those using gas and electricity. The commission may prescribe methods of keeping accounts and books by gas and electric corporations, and will have supervision of the power companies at Niagara Falls and other places. It may require each company to file an annual report showing in detail all its financial operations for the year, and it is vested with power to examine the books of any company. The commission is authorised to supervise the inspection of gas and electric meters by any State or municipal officer, and may adopt rules to govern such tests. It may also itself appoint an inspector of electric meters. This is not the extent of the power of the commission, as any gas or electricity company incorporated hereafter must obtain the consent of the commission before it can conduct its undertaking or issue any stock, and no existing company shall increase its capital without the consent of the commission. These restrictions should be sufficient to satisfy the most democratic, and their effect will doubtless depend largely upon the spirit in which they are exercised. Under the Tammany oligarchy there would be fruitful scope for corruption, but since the City Fathers of New York are reported to have been materially purged of that element the regulations may result in improved public services.

**Statutory Rights as to Laying of Cables.**—A point of some interest was involved in an application made last week to Mr. Justice Warrington. The applicants were the Wandsworth Borough Council, who sought to restrain the London United Tramways Company from opening roads under the Council's jurisdiction for the purpose of laying cables from the Lots-road generating station of the Underground Electric Railways Company of London for the transmission of power to work the tramway company's projected lines in Surbiton, Kingston, and Wimbledon. The company's Act states that "the company may execute all such works . . . as may be necessary or convenient for the working of the tramways by mechanical power . . . or for providing access to or forming connections with any generating station," etc. The Council contended that this only entitled the company to open the streets for the purpose of obtaining a supply of power from generating stations belonging to the respondents themselves. Mr. Cripps, K.C, on behalf of the Council, characterised as "absurd" the company's claim to connect with "any generating station," remarking that under such circumstances they might have it conveyed from John o' Groats. Mr. Balfour Browne, K.C., pointed out the obvious answer to this latter argument, and stated that there was not only no obligation upon a company to provide its own generating station, but that it was quite a common thing for the local authority to insist upon supplying the power themselves. His Lordship held that there was nothing in the Act to restrict the words "for providing access to or forming connections with any generating station" to a generating station belonging to the company, or that in making the connections the company were confined to the streets in which the trams were to run. This is surely the common-sense interpretation of the Act; indeed, it is a little difficult

Digitized by Google

to see how anybody could place a different construction upon it.

**Acceleration Tests.**—The results of a series of tests conducted by the New York Central and Hudson River Railroad and the General Electric Company on a "Pacific" type of steam locomotive and an electric locomotive having practically the same weight on the drivers are described in the *Electrical World* of New York. These tests show a marked superiority in favour of the electrically-driven locomotive. The run was made on April 29. Each locomotive was required to haul a six-car train, the total train weight being 487 5 tons for the steam locomotive and 427 tons for the electric locomotive. The line E.M.F. during acceleration was 680 volts for the series and the series parallel positions and 515 for the parallel position of the controller. These conditions of voltage were as nearly as possible what will obtain in actual practice within the electric zone in the neighbourhood of New York. The tabulated results are as follows:

| | Steam. | Electric. | Difference in favour of electric. |
|---|---|---|---|
| Length over all | 67ft. 7⅜in. | 36ft. 11¼in. | 30ft. 8⅛in. |
| Total weight (including tender for steam locomotive) | 342,000lb. | 200,500lb. | 141,500lb. |
| Concentrated weight on each driving axle | 47,000lb. | 35,500lb. | 11,500lb. |
| Revenue bearing load back of locomotive | 256 tons | 307·25 tons | 51·25 tons |
| Acceleration miles per hour per second averaging up to 50 miles per hour | ·246 | ·394 | ·148 |
| Time required to reach speed of 50 miles per hour | 203 seconds | 127 seconds | 76 seconds |

The electric locomotive from the first turn of the wheels accelerated faster than the steam locomotive, and at a distance of 1,500ft. from the starting point the electric locomotive led by a train length. At all speeds the smooth running qualities of the electric locomotive were very noticeable.

**Theory of the Electrolytic Rectifier.**—In the May issue of the *Physical Review* (New York) there appears an article upon the theory of the electrolytic rectifier from the pen of Mr. S. R. Cook, who has investigated the subject in some detail. The author's conclusions are that whenever oxygen is the primary or secondary product of the anion, the aluminium anode is covered with a film of hydroxide which has a very high resistance, so high, indeed, that it acts as a dielectric to the charge on the ions. This non-conducting film between the metallic aluminium and the electrolyte produces a condenser effect with the negative charge on the anions of the electrolyte. The conditions then that always exist, when a direct current is applied to an electrolytic rectifier with a well-formed aluminium anode, are: (1) When any potential less than the critical potential is applied to the electrodes there is induced an equal and opposite charge in the electrolyte next to the respective electrodes. (This is on the assumption that the film acts as a perfect dielectric.) (2) When the current is broken there exists bound charges in the electrolyte and on the electrodes. These bound charges on the electrodes, which may be assumed to be equal to the bound charges in the electrolyte, are what produce the counter E M F. The curve of decay shows the rate at which these charged ions pass through the film and give up their charge to the metallic plate. (3) When the current is reversed the hydrogen ions pass through the film more readily than the oxygen or other negative ions, forming a gas between the metallic aluminium and the film, thus breaking away the film and exposing the metal to the charged ions. (4) When an alternating current is applied, the film acts as a semi-permeable membrane. The hydrogen atoms having less mass and greater velocity than the oxygen or other negative ions, pass through much more freely than the more slowly-moving anions. (5) The critical potential value for an electrolytic rectifier depends upon the electrolyte used and the temperature of the cell. When the critical potential has been passed, the film crystallises and in crystallising exposes the metallic aluminium. The crystallisation continues so long as the potential is kept above the critical value.

**Institution of Mining Engineers.**—The fifteenth annual report of this institution affords interesting reading. The institution includes in its membership six different societies—viz., the Midland Counties Institution of Engineers; the Midland Institute of Mining, Civil, and Mechanical Engineers; the Mining Institute of Scotland; the North of England Institute of Mining and Mechanical Engineers; the North Staffordshire Institute of Mining and Mechanical Engineers; and the South Staffordshire and East Worcestershire Institute of Mining Engineers. The membership for the last 15 years shows a steady increase, the total for 1904 being 2,781. The Manchester Geological and Mining Society applied to join the society during the year, and their request has been cordially agreed to. The report gives a list of the numerous papers which have been read before the different societies during the past year. Those dealing with applications of electricity have, in certain instances, already been abstracted in our columns, but the following list will be of interest, as it will serve as a reference to the source of much useful information. These papers are: "Notes on Glapwell Colliery," by Mr. M. Deacon; "An Electrical Heading Machine," by Mr. Percy C. Greaves; "The Three-Phase Electric Haulage Plant at Shirebrook Colliery, Mansfield," by Mr. William Hay; "A Comparison of Three-Phase and Continuous Currents for Mining Purposes," by Mr. Roslyn Holiday; "Comments on the Proposed 'Rules for the Installation and Use of Electricity in Mines,'" by Mr. William Maurice; "Notes on Electric Power applied to Winding in Main Shafts," by Mr. W. C. Mountain; "Comparison of Electric and Compressed-Air Locomotives in American Mines," by Mr. Beverley S. Randolph; "Description of the Duddingston Shale Mines and the Niddrie Castle Crude Oil Works," by Mr. J. Balfour Sneddon; "Alternating Currents and their Possible Application to Mining Operations: Part II.—How Alternating Currents may be Used in Mining," by Mr. S. F. Walker; "The Report of the Departmental Committee on the Use of Electricity in Mines," by Mr. S. F. Walker; "Electric Coal-cutting," by Mr. W. Walker.

**Electricity in German Mines.**—The paper read by Mr. E. O. Forster Brown before the Mining Institute of Scotland early this year has just been printed in the *Transactions* of the Institution of Mining Engineers. The author gives some interesting figures as to special cases in which electrical energy has been applied to winding engines, hauling gear, pumping, etc., in various mines in Germany. Amongst the pumping plants were noticed one installed in the Victor Colliery at Rauxel, in Westphalia. The feature of the equipment is the high lift obtained with centrifugal pumps. The steam-engines and three-phase alternator installed are used for supplying the pump motors only. The three-phase alternator runs at 112 revolutions, and generates current at 5,000 volts, which is transmitted to the motor-driven pumps at the pit bottom some 1,640ft. from the surface. The centrifugal pump is of the Sülzer type in two parts, each part is in four steps and is driven by a separate motor; the first pump sucks the water from a depth of 13ft. (4m.), and delivers it to the second part at half the velocity required for the total lift; and the second part supplies the remaining velocity required. The

Digitized by Google

motors, of 600 h.p. each, are keyed on the same shaft as their respective pumps, and run at 1,035 revolutions a minute. The total vertical lift exceeds 1,640ft. (500m.), and the total quantity of water pumped is 1,540 gallons per minute. As the generating plant only drives the pump, the motors of the latter do not require to be switched on underground, but start working with the steam-engine at the surface. From the results of tests made of this pumping plant running under normal conditions, it appears that the efficiency of the pump is 75 per cent., and of the dynamo, cable, motors, and pump 60 per cent. The author describes also some winding gear in one or two mines, of which we have already given particulars in our columns. It is interesting to note his general statement that the new plants are, with rare exceptions, worked on the three-phase system because the machinery for the same is cheaper to construct than for direct-current working. It also admits of higher voltages being economically used, which keeps down the cost of the cables. The three-phase system, however, is disadvantageous for those machines where speed regulation of the motor is required, though even for such purposes a good deal of three-phase current is used.

**Power Distribution.**—An article in the May number of *Electrics* discusses the subject of the supply of power in bulk to collieries and the like. To meet the contention of some owners that they can generate energy more cheaply than a power company can supply it, the writer specifies the conditions that have to be met. The colliery may require an average through the day, say for 10 hours, of 1,000 h.p.; a maximum now and then during the day of 1,500 h.p.; an average throughout the night, say for 10 hours, of 250 h.p.; a maximum now and then during the night of 500 h.p. Nothing at all (unless for ventilating) for, say, four hours in each day, between shifts, etc. This gives an average over the 24 hours of, roughly, 600 h.p. But in order to get this a plant must be installed that can supply the maximum possible demand—*i.e.*, 1,500 h.p.—or 2½ times as much as is ordinarily required. Such a plant, however, would not be sufficient in case of a breakdown, or during repairs. If to supply 1,500 h.p. of maximum demand two engines and generators are required of, say, 750 h.p. each, then, to make things safe, a third 750-h.p. set must be provided in case of a breakdown, or during repairs to one of the other sets. The colliery that wishes to be independent will therefore have to buy 2,250 h.p. of generating plant, engines, boilers, switchboard, accessory plant, buildings, and foundations in order to cope with an average demand of 600 h.p. In other words, it will have to pay nearly four times over for its plant. No colliery company, unless it is a very large concern with many pits near together that can be served from one central point, can hope to have a load factor sufficiently high to make its costs low enough to compete with the selling price of a power company. If the colliery is a "whole hogger" in electrics, the load factors of its various appliances may be as follows:

| | | | |
|---|---|---|---|
| Ventilating ..... | say 250 h.p., | 100 % | load factor |
| Winding ..... | „ 1,000 „ | 20 % | „ |
| Pumping ..... | „ 200 „ | 50 % | „ |
| Haulage..... | „ 1,000 „ | 25 % | „ |
| Surface and other machines | „ 300 „ | 12½ % | „ |
| | | | average |
| Total ..... | 2,750 h.p., | 36 % | load factor. |

Exception may be taken to the above load factor of 20 per cent. for winding, but on close examination it will be found to be, if anything, over the mark. If coal is raised continuously for nine hours out of each 24, it is safe to say that full power—whether steam or electricity is immaterial—is applied to the winding drum for less than two hours. For about another three hours a varying amount of power is used, but during the remainder of the nine hours braking is taking place, or the cages are at rest. The writer gives this as one of the examples most favourable to independent plant. He then gives reasons why the colliery proprietor can operate more advantageously by taking supply in bulk. Although the power company pays more for its coal, it can claim economy not only in the size of its units of plant, the centralisation and consequent reduction in its establishment charges, and its small transmission losses, but it has the valuable asset of a highly diversified power factor. The company is thereby enabled to deal with a very large connected load by means of a comparatively small running plant.

**The Telephone Transfer.**—Prior to the spirited scenes which brought the deliberations of our legislators to a summary conclusion on Monday night, the members of the House of Commons found time to consider the motion for the appointment of a select committee to consider the agreement with the National Telephone Company. In reply to sundry criticisms, Lord Stanley stated that the committee would have all the powers of an ordinary select committee, and could make the fullest enquiry, and report to the House, but it would not have power to alter the terms of the agreement. It might, however, make recommendations, and he would have to consider whether, in view of any such recommendations, he could go on with the agreement. If the House did not accept the agreement as a whole, it would fall to the ground. He promised that the House should have an opportunity of giving a definite decision before Aug. 31. After further criticism, Lord Stanley agreed to the insertion of words under which the committee, if it made any recommendations as to modifications in the agreement, might report whether it should be affirmed with such modifications. The motion was then carried, and the committee constituted as follows: Lord Bingham, Mr. Benn, Sir Horatio Davies, Mr. Keir Hardie, Mr. Helme, Sir William Holland, Mr. Lambton, Mr. Morrison, Mr. Joseph Nolan, Sir Charles Renshaw, Colonel Royds, and Mr. Stuart-Wortley. The provision empowering the select committee to make recommendations for varying the terms of the agreement is calculated to diminish any chance of the negotiations proving abortive after all. At a conference at the Westminster Palace Hotel on Monday of county boroughs of England and Wales and of Scotch cities and boroughs (Alderman J. W. Southern, of Manchester, in the chair) a resolution to the following effect was submitted: "That, inasmuch as the agreement between the Postmaster-General and the National Telephone Company, dated Feb. 2, 1905, fails to provide for a cheap and efficient telephone service for the whole country, this conference of county boroughs of England and Wales and of the principal cities and burghs of Scotland, whilst expressing no opinion as to the principle of State control of the telephone system, desires to record its strong disapproval of the terms of the agreement, and viewing as it does the proposal with much apprehension, desires to place its objections in detail before the Select Committee." An amendment was proposed in favour of supporting the agreement, but asking the Postmaster-General to reconsider the whole system of telephone rates, with a view to reducing them and making them more commensurate with the degree of user of the various subscribers, and also asking that adequate provision be made for the benefit of local authorities in regard to wayleaves and contributions in lieu of local rates. This was negatived. Another amendment was proposed approving of the agreement, but urging that all necessary provision should be made for safeguarding the interests of municipalities, whether owning their own telephone system or not. This was also negatived, and

Digitized by Google

the original motion was carried. Alderman Southern and Bailie James Alexander (Glasgow) were appointed to take all necessary steps for bringing the resolution before the Select Committee.

**Pneumatic Dispatch Scheme.**—A number of important witnesses have given evidence on this subject before the Committee of the House of Commons presided over by Sir Henry Aubrey Fletcher. The inventor of the system underwent an extensive cross-examination, as also did Mr. A. E. Stuart, one of the syndicate's engineers, both witnesses giving testimony substantially on the lines of the general scheme that has been made public. Mr. Stuart did not believe that any block would arise from the dispatch of evening newspapers at certain hours of the afternoon in addition to the ordinary traffic. The reason why the pneumatic tunnel for the dispatch of mails from the General Post Office to Euston Station was given up was because the mails were sent along in train loads, so that when they reached Euston the unloading took so long that all the advantage of the tube was lost. The cardinal principle of conveyance by pneumatic tube was frequency of dispatch. Parcels would be dispatched at the rate of 600 per hour. Sir John Wolfe Barry considered that no undue degree of inconvenience would arise from the opening of the streets, the cut-and-cover method being employed, and that the scheme would be of great utility. Colonel Crompton stated that he had made a study of the pneumatic system, and had thoroughly investigated its working in New York, Philadelphia, and Boston with a view to its applicability to London traffic. The Post Office authorities in the United States had informed him that interruptions to the tube traffic were so rare as to be negligible. With a sufficient network of tubes leading out of the congested newspaper district the company would be capable of dealing with a far larger amount of traffic than the newspapers would furnish. The promoters had placed observers at various points in the streets who took note of the amount of parcel traffic of the same kind as the tubes would carry. The calculations based on their observations were that the establishment of the scheme would take 19 6 per cent. of the cart traffic off the streets. Dealing with the objections to breaking up the streets, Colonel Crompton said the idea was to have the pneumatic tubes laid below gas and electric mains, and once they were laid it was unlikely they would have to be touched for years. Sir Alexander Binnie, formerly chief engineer to the London County Council, believed the scheme would be a great benefit to the public, and would do a great deal towards relieving the congestion of street traffic. In his opinion the system had gone beyond the point of experiment. As an engineer he saw nothing to militate against its successful working. It is understood that the attitude of the Postmaster-General will be influenced by that of the London County Council and the City Corporation. There will probably be no occasion for the committee to defer their decision until the report of the London Traffic Commission has been issued, Sir David Barbour, chairman of the Commission, having intimated that the scheme is not likely to be affected by the report.

**Telephony in Canada.**—We have received copies of reports, aggregating 14 in number, prepared by the Select Committee appointed by the Canadian Government to enquire into the subject of telephonic control. These reports bring matters down to April 19. The committee, which is sitting at Ottawa, is composed of Sir William Mulock, Mr. Boyce, Mr. Burrows, Mr. Demers (St. John's and Iberville), Mr. Grant, Mr. Johnston (Cape Breton, South), Mr. Maclean (York), Mr. Monk, Mr. Roche (Marquette), Mr. Smith (Nanaimo), and Mr. Zimmerman. Investigations have been made into the systems in vogue in various parts of the world, and also into the effect of competition between the Bell and the independent companies in the States. It appears that there are a number of rural systems in operation in Canada at a cost far below the tariff of the Bell Company, whose terms for connection with their trunk lines are of a most onerous character. To further promote monopoly the Bell Company have entered into agreements with nearly every railway company for excluding the users of the local telephone systems from obtaining connection with the systems owned by such companies. In certain parts of Ontario and Quebec, for which the Bell Company on being approached by would-be customers had demanded prohibitive terms, local co-operative associations have supplied a service at a fraction of the charge required by the Bell Company. The systems have been installed by these local companies at a cost of from £7 to £10 per instrument, and the expense of operation and maintenance is stated to have been so small as to be hardly worth considering; in fact, the message fees from non-subscribers are more than sufficient to meet these charges. The opinion prevails in certain quarters that with Government ownership of the trunk lines and municipal or private control of the local systems the telephone industry of the Dominion would receive a great impetus, and might well be consolidated into an admirable system. Amongst the witnesses who have been heard before the committee was Councillor J. Willock, the chairman of the Glasgow Electricity Committee. He was able to give the committee intimate details as to the methods by which the large undertakings of the Glasgow Corporation are organised, financed, and controlled. He spoke well of the Glasgow telephone undertaking, and stood a severe cross-examination on the same. Amongst the points on which he was questioned was that of local management *versus* Government control. Mr. Willock favoured the Government working of trunk lines, but considered that corporations were better adapted for conducting local exchanges. His reason for this was that when the Government expropriate the company and the corporation he thought they would pay too much for the plant acquired, and hence would not be able to give telephone connections at the same rates as now obtain under the Glasgow Corporation system. He explained that in Glasgow the tramways, the gas, the electricity, and the telephone departments are so worked that no considerable profits are made. If there is a surplus, this goes in reduction of the cost of the individual service by which the surplus has been earned. Owing to this, the tramway fares has been reduced by over 50 per cent. since the Corporation took them over. At the same time, any profit from one department is not used to reduce the rate of charges in another. He considered that the telephones in Glasgow were paying their way, and that competition had resulted in a very large increase in the actual number of telephones used. Both the Corporation and the National Telephone Company gained by the competition, and while there were interchanges of subscribers between the two concerns the net result was an increase in the total number. Telephones were now much more used in Glasgow for private houses than they were before the competition commenced. The third annual report of the Corporation telephone department was gone into in detail before the committee, but as we have already given the essential figures from this we do not propose to reproduce them as given by Mr. Willock before the Canadian Committee. This interchange of ideas between large home corporations and the Colonies has every advantage, and we are glad to observe that the Canadian Committee were impressed by Glasgow's success in municipal work.

## MESSRS. ERNEST SCOTT AND MOUNTAIN'S NEW WORKS AT GATESHEAD.

Messrs. Ernest Scott and Mountain commenced electrical manufacturing in 1888, when Mr. W. C. Mountain joined the firm. In those days machinery for electric lighting was the chief output from the electrical department of the firm, which had previously acquired a good reputation for manufacturing pumps and auxiliary machinery for warships. Mr. Mountain, however, recognised that at an early date there was a considerable future in connection with the adaptation of electricity for pumping, hauling, and coal-cutting in mines and collieries, and in the year 1890 the firm carried out their first mining contract, this being an electrical pumping installation for the Cowpen Coal Company, for their North Seaton Colliery, near Blyth. The plant consisted of a steam-engine, with generator, three-throw pump, and motor, the pump being placed at a distance of nearly two miles in-bye, and delivering 300 gallons of water per minute. Other orders quickly followed, and the next important contract was for a set of main shaft pumps for the Lothlan Coal Company, near Edinburgh, which was suggested by Mr. John Morison, now of Cramlington, who was at that time general manager to the Lothian Coal Company. To begin with, two sets of pumps were installed, delivering a total of 230 gallons per minute against a head of 790ft., with generating machinery at bank, and shortly after a third set was supplied. This company have now so far extended their electrical machinery that in all they have about 16 sets of pumps working at their various collieries. Applications of electricity to underground haulage on an extensive scale followed, and one of the largest installations which the firm carried out in those days was that for the Broughton and Plas Power Coal Company, Wrexham. The first plant consisted of a horizontal steam-engine and rope-driven dynamo, with an endless rope haulage gear placed 1,200 yards from the bottom of the shaft. This gear was fitted with three rope wheels, and worked by a 150-h.p. electric motor, the total length of the three roads operated being 4,600 yards. The generating machinery was placed in a house at bank, and provision was made for the addition of further sets. The firm were also among the first to apply electricity to coal-cutting, their earliest machine, of the disc type, being supplied to Mr. G. A. Mitchell, of Glasgow, for one of his collieries, about 12 years ago. This earlier work in the application of electricity to mining work was carried out with direct-current machinery, but the firm were amongst the first to introduce three-phase plant into English and Welsh collieries. Their first installation with this class of machinery was for the Tredegar Coal and Iron Company, at their Pochin, Ty Tryst, and Bedwellty Collieries in South Wales. This is now one of the largest and most successful installations in the United Kingdom. At the Pochin Colliery the plant consists of two engines, each of 360 h.p., each driving a 250 kw. three-phase alternator, the underground equipment including two main and tail haulage gears of 55 h.p., and two endless rope haulage gears of 75 h.p. each, together with main shaft and in-bye pumps, and smaller pumps, etc.

The old works of the firm were situated at Newcastle, in the Close. The space there available between the river front and the street was limited, and for this reason the firm had to curtail their field of operations. Thus in the earlier days they manufactured some marine engines, but this branch had to be given up to make room for the electrical department and the manufacture of high-speed engines. Even then, when we paid our last visit to the old works some 18 months ago, we were struck by the congested state of the shops and by the large variety of plant which was going through. The new works, which were officially opened on Saturday last, are situated in Gateshead, on the site of engineering works which were formerly used by Messrs. Black, Hawthorne, and Co. Part of the old shops have been utilised, but the bulk of the covered-in portion of the site is taken up by new buildings erected specially for the firm. The result is a thoroughly equipped, up-to-date factory, which should enable the firm to execute a larger volume of orders much more promptly than they could possibly have done in the old works.

Out of the total area of seven acres, as shown in Fig. 1, two acres are roofed in. There is a direct siding to the North-Eastern Railway, so that material can be handled without transhipment and at a minimum of cost. There are four separate buildings on the site. The largest has four bays, one of which is no less than 558ft. long and 43ft. wide. The north-west bay forms the light machine

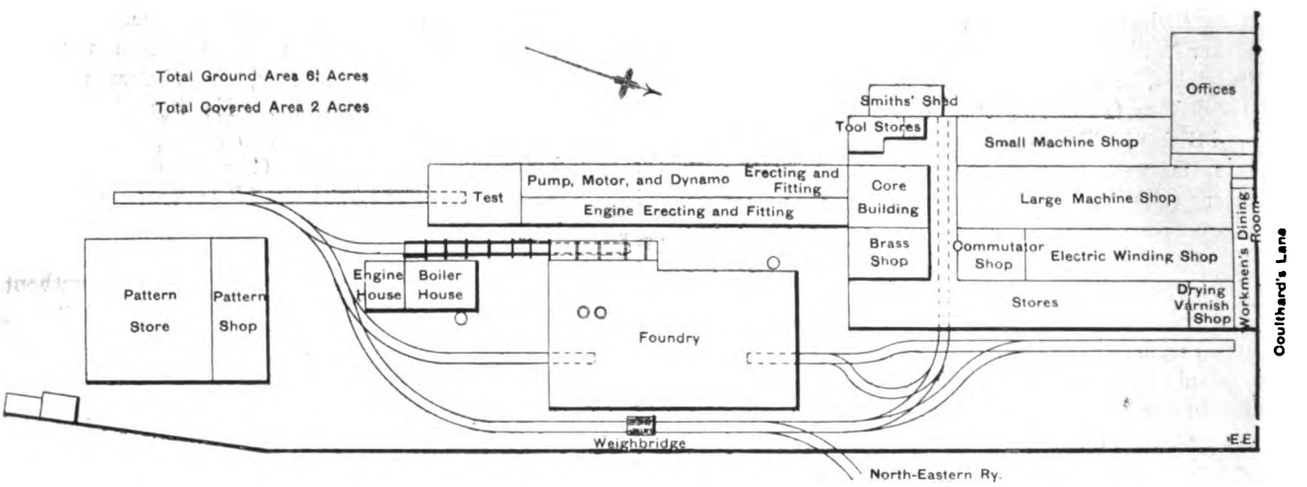

FIG. 1.—Plan of Messrs. Ernest Scott and Mountain's New Works at Gateshead-on-Tyne.

shop, and is 234ft. long by 34ft. wide. It includes all the light machinery, such as small lathes, slotting and milling machines, etc, while at the end of the shop is the tool store and tool fettling department. The smiths' shop is situated on the west side of this bay, in a building specially constructed for the purpose. The large bay comprises the heavy machine tool shop, the core-building department, and the general erecting shop and light fitting department, the far end being devoted to the testing of all classes of machinery. The machine tools in this bay include a planing machine which will take work 20ft. long, 6ft. 6in. high, and 8ft. wide; a 27in. centre lathe; a 20in. vertical lathe; and three boring mills each capable of boring up to 10ft. diameter. The erecting shop (Fig. 2) is provided with ample accommodation in the way of benches, with vices, etc., wall drilling machines, and a great variety of portable tools used in the erection of the specialities of the firm. The shop is served by 15-ton overhead electric travelling cranes. The testing department includes a very complete equipment for the testing of high-speed engines, dynamos, electric motors, three-throw and centrifugal pumps, etc. The third bay in the main building forms the electric and brass shop, in which the whole of the armatures, field magnets, commutators, and other electrical details are constructed. The shop is 264ft. long and 34ft. wide, and the adjoining shop of the same size is utilised for general stores. The foundry is a separate building, 175ft. long, 112ft. wide, with a floor space of 18,000 square feet, and here are two cupolas of a combined capacity of 11 tons per hour. The brassfoundry

Digitized by Google

is under the same roof, and the light moulding is carried out in a small bay at the east side of the foundry. Almost adjoining the foundry is the boiler-house and electric generating station, where a large portion of the electric current for driving the works is produced. The pattern shop and stores consist of three bays in one building, 100ft. by 120ft., and the department is fitted up with modern wood-working tools. Ample space is left on the site for future extensions, and these can take place at any time without interfering with the continuous working of the present shops. The whole of the shafting in the various departments is operated by electric motors so placed as to not

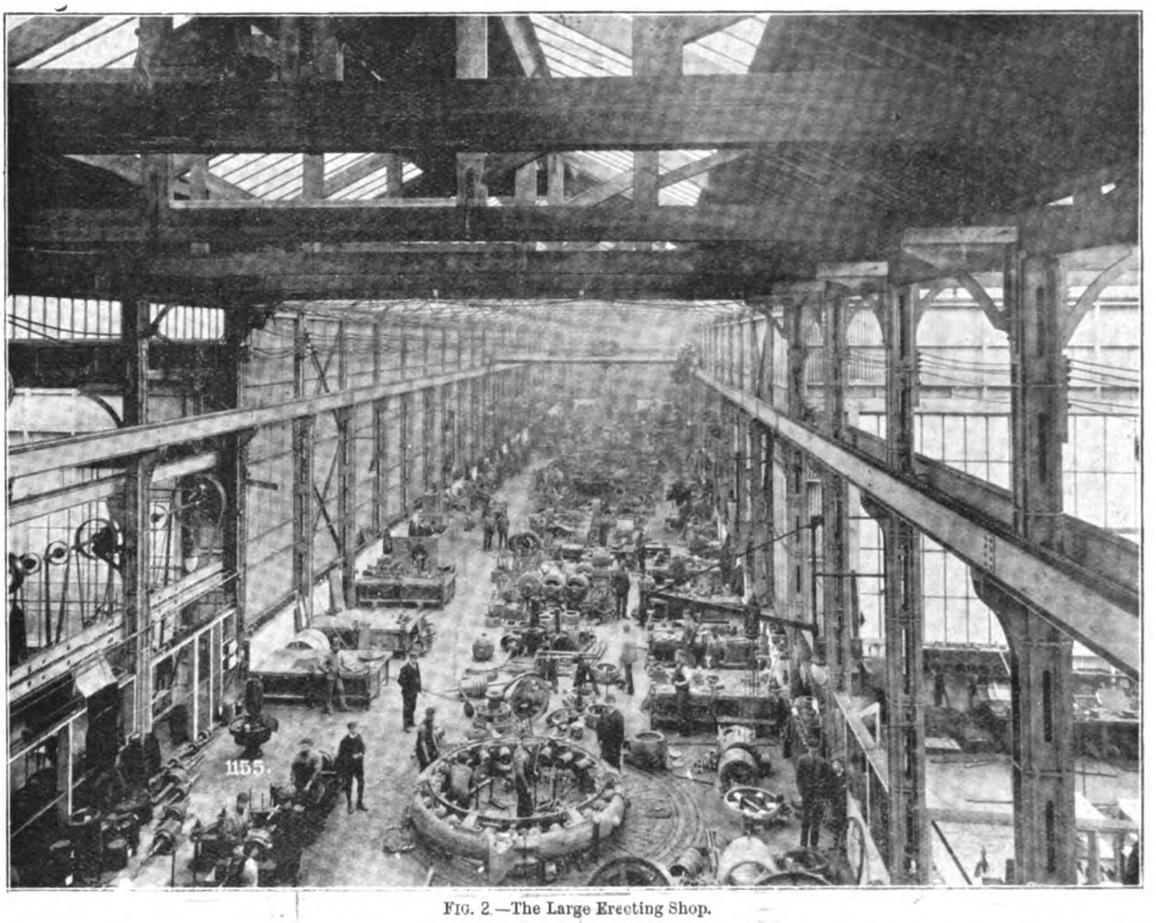

FIG. 2.—The Large Erecting Shop.

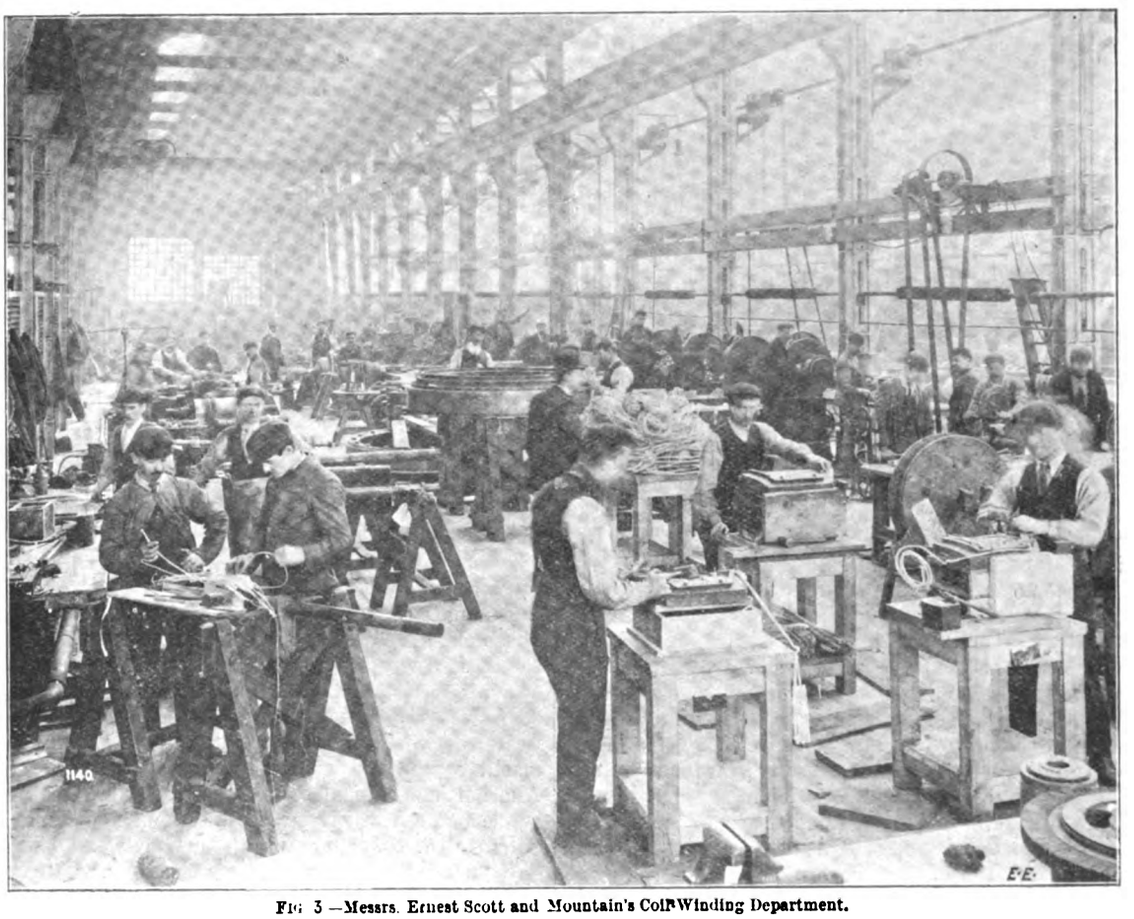

FIG. 3.—Messrs. Ernest Scott and Mountain's Coil-Winding Department.

Digitized by Google

interfere with the general working of the machinery, and the shops are heated by live steam. The offices are large and well arranged, and, in addition to a dining-room for the staff, there is a dining-room for the workmen, where accommodation is provided for about 200 to sit down, and special cooking facilities are afforded. Every department is in communication with the office and the other parts of the works by means of a private telephone system.

In Figs. 3 and 4 we give views taken in the armature-winding department, the first of which shows the preparation of the coil on formers, and Fig. 4 the building up of these former-wound coils on to the armature cores. The feature which specially struck us in our inspection on Saturday last was the large variety of plant which the firm had under erection in their shops. In spite of the variety it was evident that mines and collieries would find a use for practically all the material in question. A large number of pumping plants, for instance, were under construction, including two sets of three-throw horizontal pumps with rams 18in. diameter by 22in. stroke for the Consett Iron Company, each pump being capable of delivering 1,500 gallons per minute against a working head of 400ft. when

Amongst the large electrical machinery going through the shops we were particularly struck with two machines of 300 kw. which are being manufactured for the Mickley Coal Company, near Newcastle. These machines are large for their output, due to the fact that they are to be driven by engines running at 100 revolutions per minute. The field-magnet system, although of large diameter, is made of cast steel in two parts only. The field-magnet poles are circular in section and are provided with pole-shoes, which present a flat surface to the armature. This gives a varying air-gap, which has considerable influence on the commutation of the machine.

Amongst the engines of the high-speed type which were on view was one with three cranks for compound working. It had one high-pressure cylinder 13in. in diameter and two low-pressure cylinders, each 16in. diameter. In each case the stroke was 9in. This engine is one of three in course of manufacture for Messrs. J. Ross and Co, Philipstoun Oilworks, Linlithgow, N.B. They will each develop 350 effective horse-power. The engines are completely enclosed, and a system of forced lubrication is applied to all the working parts. Duplicate oil-pumps are

FIG. 4.—The Armature-Winding Shop.

running at a speed of 26 revolutions per minute. These large pumps will be driven by electric motors from the generating plant, which Messrs. Ernest Scott and Mountain are also supplying. The motors are connected to the countershaft of the pump by means of ropes, and there is a further reduction by spur gear to give the speed of 26 revolutions on the main pump shaft. Amongst the electric winding gears almost completed was one for Swalwell Colliery, fitted with double drums, one drum being 5ft. diameter and the other 7ft. 6in. diameter, for winding from two levels. This gear is capable of dealing with 100 tons per hour from a depth up to 300ft., and will be driven by a three-phase electric motor of 150 h.p. complete, with special regulating gear for reversing and varying the speed. A number of haulage gears were also on view, including one of the endless rope type for the Azov Coal Company, Russia. This had a rope wheel 5ft. diameter, and was driven by a 40-h.p. motor. This gear is complete with friction brake and friction clutch, and is driven through a train of machine-cut gearing, the whole being mounted on a steel girder bed-plate made in sections for taking to pieces and getting in-bye.

used for the purpose, which are driven from an eccentric on the engine shaft. The oiling of the crank-pins is not carried out through holes in the crankshaft, but the oil is led through the cross-head guides to each cross-head pin and then down to the crank-pin by means of a pipe. This method of carrying the oil to the crank-pin leaves the crankshaft its full strength.

Amongst the mining material on view there was a three-phase electric coalcutter of the disc type. The feature of the design was that to save headroom the induction motor was arranged with a vertical spindle. The motion was then transmitted through a series of spur and bevel gearings to the disc in which the cutting tools were carried. The machine we saw could undercut to a depth of 4ft. 6in. Another machine also on view, but driven by a direct-current motor, was arranged to do much the same undercut. A list of the other pumping plants, air-compressors, haulage gear, and other mining accessories which we saw would be tediously long. It suffices to say that every type of plant for use in collieries and mines was represented.

The opening ceremony on Saturday last was performed by Lord Armstrong in the presence of a large gathering of

Digitized by Google

representative visitors. In the course of his speech Lord Armstrong thanked Mr. Scott and the directors of the firm for the invitation to the opening of the works, which he felt would do a great deal to increase on the Tyne the industry connected with electricity. He considered that the firm had shown themselves among the leaders and pioneers in this country in the utilising of electricity for

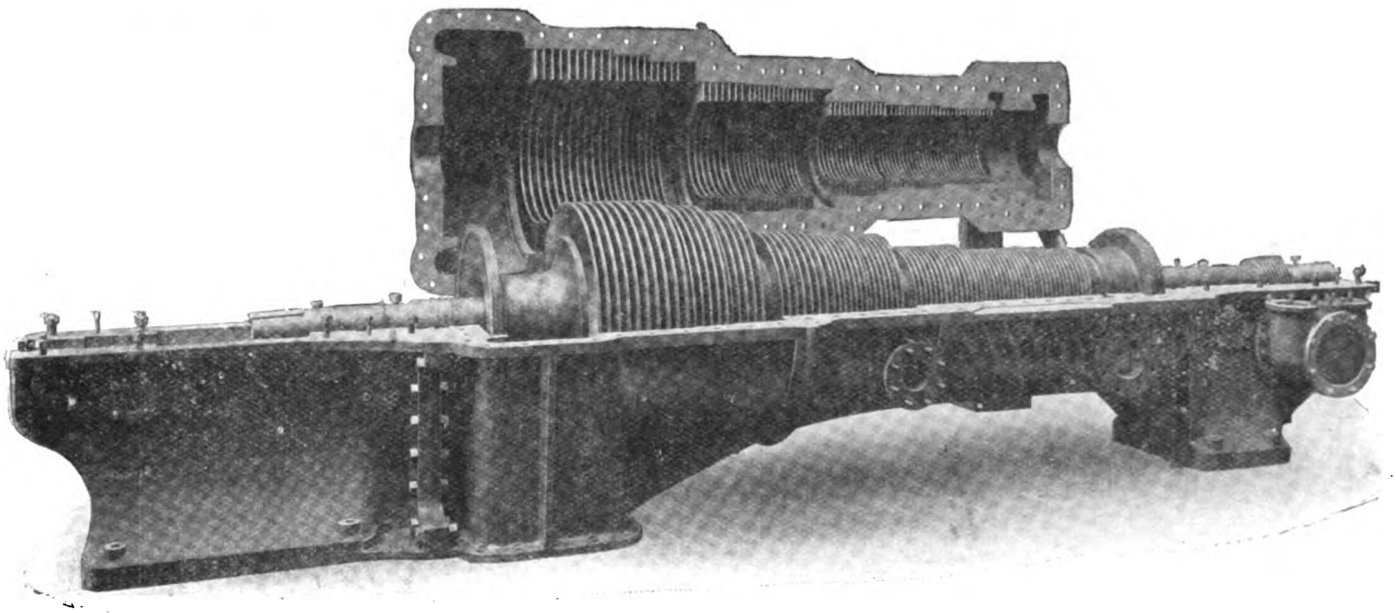

FIG. 1.—View of a Willans-Parsons Steam Turbine with hinged top opened, and showing Shrouded Blades and the Low-Pressure Balancing Ring.

the purpose of working in collieries. They often read in the papers of how the foreigners were going forward, and especially of how the Germans were trying to oust Englishmen in every part of the world, but as long as they had energy and enterprise shown in this country such as they had in the past, and the good work turned out which was being turned out at the present time, he had no fear that the Germans or anybody else would take away the reputation which had been won, or oust England from the commercial field.

## THE WILLANS-PARSONS STEAM-TURBINE.

It is now more than two years ago since Messrs. Willans and Robinson, Limited, decided to take up the manufacture of steam-turbines, and after a careful survey of the work being done in the direction of building turbines of different types, not only in this country but on the Continent and in America, they decided that the parallel-flow turbine, on the system proposed and developed by the Hon. C. A. Parsons, had stood the test of time and was in a more advanced position for manufacture on a large scale than any other. Negotiations were entered into with the Hon. C. A. Parsons and Co., and a license to manufacture under their patents was taken. Consequently the Willans-Parsons turbine is identical in principle and in its main features with the Parsons standard type, and it is only in details of design and manufacture that there are any differences. As, however, these alterations have been introduced with a view to lending greater flexibility to the turbine when in use, and facilitating manufacture on the interchangeable system, a few remarks on the subject may be of interest.

Special attention has been given to the arrangement of the necessary details, such as governor gear, oil-pump, steam and water piping, etc., as it has been found that ability to inspect the working portion of a turbine without dismantling any attendant gear is a convenience appreciated by those who have to take charge of the running and maintenance of machinery. To enable this to be attained, all the gearing and fittings named above are mounted on the bottom half of the bearing pedestals, and the top cover of the turbine, as well as the bearing caps of the three main bearings, are left free for instant removal.

To further facilitate opening the turbine, the top half of the casing has been arranged with two hinges, thus avoiding the use of guide studs and placing the turbine cover in a suitable position for examination. In the case

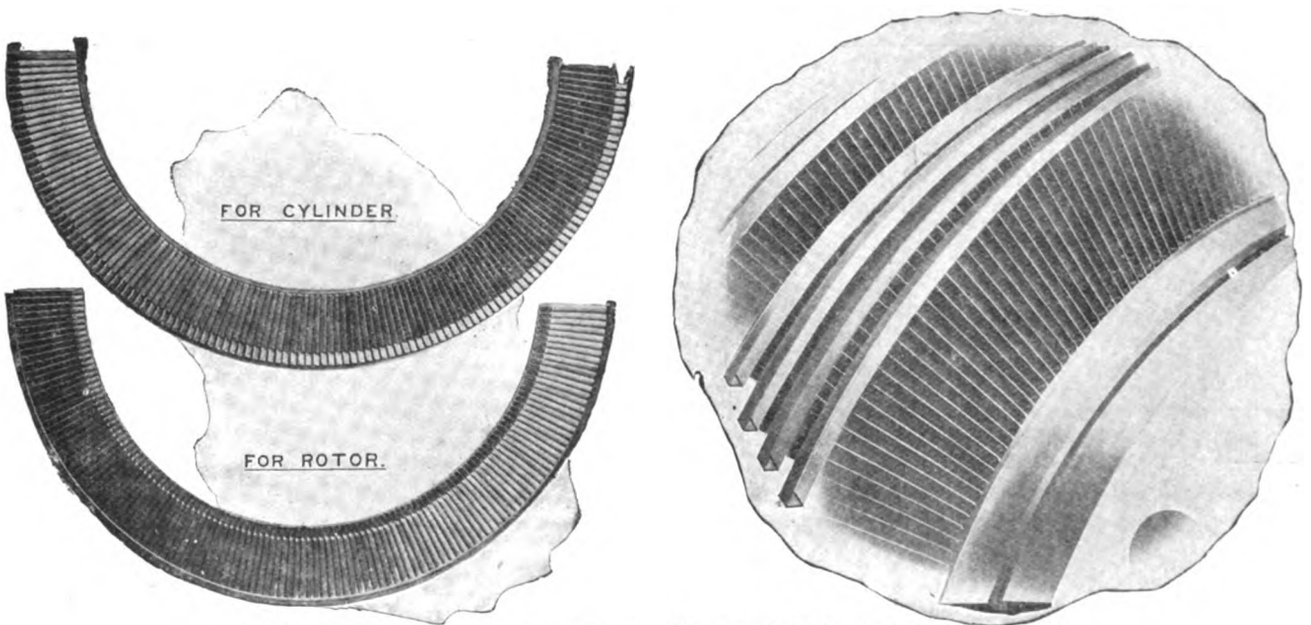

FIG. 2.—Details of the Special System of Securing and Shrouding the Blades of a Willans-Parsons Turbine.

Digitized by Google

of the 1,000-kw. Willans-Parsons turbine, it is possible for two men to remove the main bearing caps and to open up the turbine for inspection in less than an hour. A view of a turbine opened up in this manner will be found in Fig. 1.

By a rearrangement of the balancing passages, it has been found possible to somewhat shorten the length of the ordinary parallel-flow turbine and, further, due to Fullager's patent system of balancing, it has been found possible to dispense with the large balance piston at the high-pressure end of the turbine, and to substitute in its place one of considerably smaller dimensions at the low-pressure end. It has been found in practice that this method of arranging the balancing pistons has the advantage of enabling castings of a more symmetrical form to be adopted, and in this way many of the troubles brought about by unequal expansion of the different parts are avoided.

An improved method of attaching the blades to the rotor and casing has been adopted in the Willans-Parsons turbine—extraordinary stiffness and rigidity is given to the blade rings when they have been fitted into their respective body or shaft grooves. In the ordinary turbine of this type, each blade is fixed separately into the rotor and casing by means of its own caulking piece. In the Willans-Parsons steam-turbine, as will be seen from Fig. 2, the blades for one complete ring are built up on two half-rings, which rings have had the necessary grooves for receiving the blades cut in them by means of automatic machinery. These complete half-rings of blades are then caulked into the shaft or the casing. Attention might be drawn to the fact that the cutting and assembling of the blading by means of specially designed automatic machinery, ensures that the whole of the blade angles and openings on which the efficiency depends are mathematically correct.

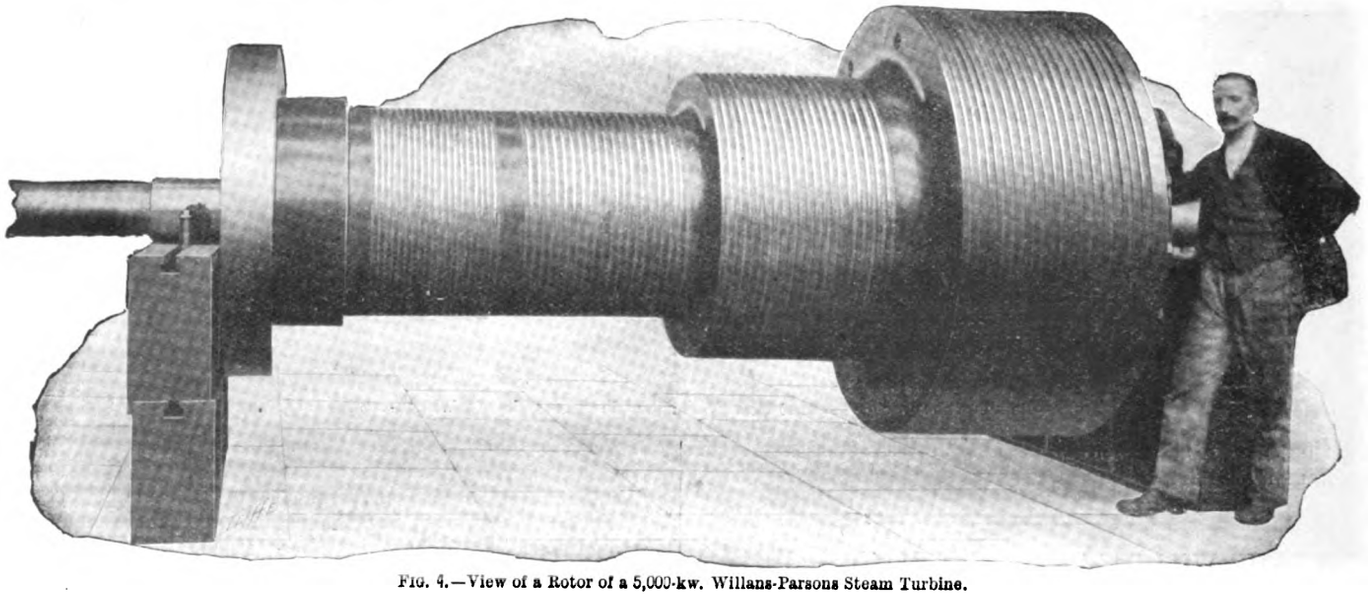

FIG. 4.—View of a Rotor of a 5,000-kw. Willans-Parsons Steam Turbine.

Digitized by Google

Fig. 2 shows two of these half-rings complete for assembling on the shaft and in the casing.

Another feature of the Willans-Parsons turbine consists in the special channel shrouding encircling the blades, which Messrs. Willans and Robinson have the right to use under the patent of Mr. H. F. Fullager. This shrouding is fixed on the half-ring of blades before assembly on the shaft, or in the casing, and has several points of merit. It adds materially to the mechanical strength of the blades themselves and removes any danger of the blades stripping, should the rotor come into contact with the casing, or the blading on the casing come into contact with the revolving shaft. Further, the action of the channel shrouding when under working conditions minimises the loss due to leakage over the revolving or fixed rows of blades, and by this means a considerable gain in the steam economy is effected. A view of the shrouding round the blades is shown on the right-hand side of Fig. 2.

Special attention has been paid to the question of governor gear with a view of making it as simple and as reliable as possible. By dispensing with some of the intermediate gears hitherto used on governors controlling steam-turbines, it has been found possible to eliminate many of the undesirable features, and to obtain results in the direction of close governing which it is believed surpass anything hitherto obtainable. All the turbines are fitted with by-pass valves which automatically open when the maximum economical output of the turbine is exceeded, and by means of these by-pass valves any required overload can be obtained up to the full capacity of the generator, the steam economy of the turbine being, of course, reduced.

At the present time Messrs. Willans and Robinson have 24,250 kw. of this type of turbine at work or nearing completion, the smallest at the present time being of 750 kw. normal capacity and the largest of 5,000 kw. normal capacity. Among others might be mentioned the following: two 3,000-kw. and one 1,500-kw. for the Glasgow Corporation; two 1,000-kw. for the Bristol Corporation; one 3,000-kw. for the Metropolitan Electric Supply Company, London; two 1,000-kw. for Messrs. Bruce Peebles and Co., Limited; and one 1,000-kw. for the English McKenna Steel Process Company, Birkenhead. The figures as to the steam consumption of these turbines are not yet available for publication, but we understand that some most successful trials have been made. The reputation for accurate workmanship in the production of engine parts which Messrs. Willans and Robinson have secured will be an additional recommendation of their turbines, which will supersede reciprocating engines where large units are needed. The mechanical details above described tend to give strength, durability, and economy to the turbine.

## A STUDY OF SHORT-DISTANCE TELEPHONY.

BY VALENTINE RYAN.

It would only appear natural to suppose that the universal use of electric bells would have paved the way for the general adoption of short-distance telephones; yet the demand for these telephones to-day is not what it might be—it is far behind what it promised to be some six years ago. What at one time promised to be a very popular application of electricity has made comparatively little headway. Is there any need, then, to be surprised at wiring contractors only regarding telephone work as "a side line"—something to be taken advantage of when it comes in their way—a somewhat convenient source of work to tide them over their slack seasons? Besides, all contractors appear convinced that it would never pay to make a speciality of it. Manufacturers apparently think the way to alter this state of things is to make periodical reductions in the price of their telephones and accessories. This has been done on such a scale that one does not know whether to marvel most at the profits that must have been formerly realised, or how it is that the telephones can be made and sold to the trade at the present prices and yield a fair profit. Purchasers should not receive such reductions in too favourable a way; they should rather remember that the first cost of a telephone installation is too often by no means the last.

A move in a better direction—one that would assuredly prove conducive to more desirable results—would be for the manufacturers to consider that their responsibility did not cease entirely when the telephones were delivered in good order to their purchasers. By this is meant that the makers might exhibit more interest in what was proposed to be done with the telephones in the first instance; then how these expectations were realised—this being done with a view to rendering the installing of telephones more desirable work in the estimation of contractors; also to enable them to make their telephones and accessories more adapted to the systems on which they are intended to work, by this means forming, as it were, a community of interest between the contractors and themselves. In the following article the installations shall be of primary interest; then how far the telephones and their accessories facilitate the working of the same will be pointed out.

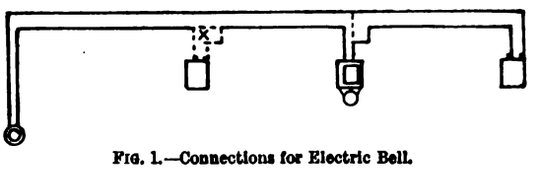

FIG. 1.—Connections for Electric Bell.

No hard-and-fast rules can be laid down for installing telephones—every installation must be considered on its own merits. An outline of the routine working of each installation should be arrived at by the contractor, and in doing so he must keep in view the routine working of the establishment, then propose such an equipment as will be convenient for the same, and submit sample telephones for approval. Considerable experience is required to arrive at the arrangement that affords the necessary communication, and still not instal one that provides means of communication such as is seldom used. The latter are not uncommon; capital is sunk in them that affords no return. Some contractors exhibit much ingenuity in this direction, others try original arrangements, and then wonder why they will not work. One has to remind them that they must modify the recognised systems to suit the particular requirements of the installation they happen to be dealing with, and only depart from the standard practice when there are substantial reasons for doing so. Telephone manufacturers deem they are generous when they issue time-honoured diagrams of connections. The original idea in drawing these was, apparently, to produce something that appeared symmetrical, and so at first sight simple; now it seems to be recognised as a tradition that these diagrams are to be rigidly copied, the only changes permitted being those that will help to identify a particular pattern of instrument. Wiremen, as a rule, do not attach much importance to them; they prefer to do things in what they call "a common-sense manner."

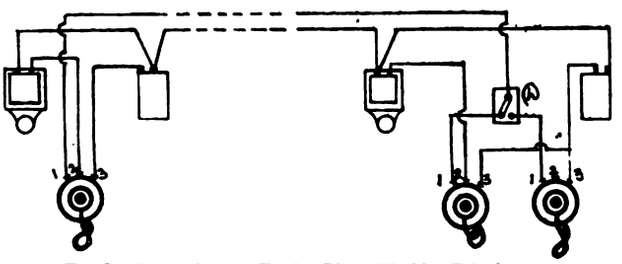

FIG. 2.—Connections for Testing Direct-Working Telephones.

The effect of the lack of interest on the part of the manufacturers, and of the contractors meeting with difficulties to which they are not disposed to devote much time, is evident in many telephone installations. The following examples, chosen for their simplicity, illustrate this, as they deal with electric bells, which form an integral part of all telephone equipments. The wiring for an electric bell is a simple piece of work. When the battery may not be placed close to the bell, as is often the case, it is the general practice to place it in some out-of-the-way corner, and lead the wires from the bell to it, as shown in Fig. 1. This mistake is frequently met with in more complicated systems of wiring, and has resulted in the waste of much time and wire. Obviously, the only correct

Digitized by Google

method of doing this is to choose any convenient place along the course of the wire and insert the battery there as is shown at X (Fig. 2). In the particulars given for installing their instruments, manufacturers never include such suggestions as might tend to economise wire, but they can afford due prominence to a price list of the same.

Ordinary electric bells are not adapted to being made in large sizes, though there is a good demand for such bells, especially for outdoor use; however, they lend themselves readily to being installed in larger numbers, which, in many respects, makes up for deficiency. Now, can a few electric bells be arranged to work in series? One would look in vain for any information on this matter in manufacturers' catalogues. Connecting the terminals in the ordinary way the action would be intermittent; two bells will work satisfactorily in series, if one armature is cut out, and the coils connected permanently in the circuit, and the armature of the second bell will break the circuit, which will suffice for both bells.

When telephones are being installed, difficulties are sometimes encountered before they are made to work satisfactorily. Wiremen seem endowed with wonderful confidence in the correctness of their work, and attribute the faults to the telephones, which they proceed to take to pieces. The same happens when a fault occurs at any subsequent period, and it can be safely asserted that only 2 or 3 per cent. of such faults occur in the telephones. In the wiring and the batteries the faults should be looked for. With the receivers placed on the hooks, any telephone installation may be considered as an ordinary electric bell one; so, when a fault arises, he should first proceed to get the bell system in order, paying no attention to the telephones

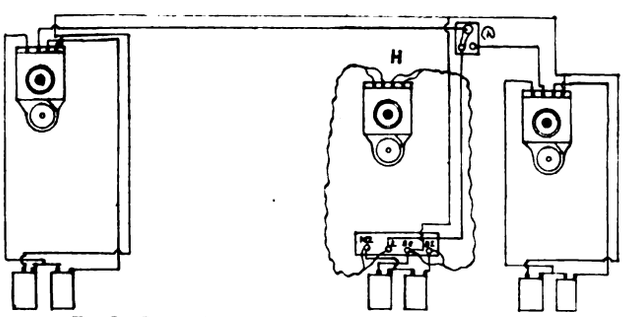

FIG. 3. Connections for Testing Induction-Coil Telephones.

proper until this is done; the transmitter, receiver, and induction coil and their connections are quite independent of the bell. Wiremen and their employers fail to realise this; some contractors test their telephones before they instal them, and thus put an end to such troubles. The more reliable way of doing this is to arrange for them to speak over a moderate distance. The following is a convenient method of doing so: First instal a pair of telephones with a view to their being of some use; then at either end arrange for connecting up a second telephone, without disturbing the connections of the first beyond altering the position of a two-point switch. This switch, D (Figs. 2 and 3), enables one to speak with either telephone, so that the person at the far end cannot tell whether he is speaking to the telephone being tested or the other one. This has a decided advantage, for it enables one to obtain the exact relative merits of the two transmitters, so that the person testing can form a correct estimate of the loudness of the transmitter at his end. When a faulty instrument is met with, the facility this method affords of restoring communication saves much time.

The connections for testing a direct working telephone are shown in Fig. 2. The battery at either station is used to ring the bell at the other; when speaking, both batteries are in the circuit, so the batteries then *must* be connected in series. Even telephone manufacturers overlook this point when they recommend a pair of cells at each end for distances of from 50 to 300 yards; this means four cells in circuit with the transmitters, which is too much. A low-resistance bell, or a more sensitive adjustment of an ordinary one, would be better advice, as the cells and transmitters are liable, in the course of time, to such variations, that it is not advisable to push matters to extremes. For the trifling extra cost induction-coil instruments prove a better investment when the distance exceeds 55 yards. Manufacturers will doubtless regard this as a very restricted limit, yet in a good majority of installations the length does not exceed that of half a coil of wire. In all other respects there is no limit to the usefulness of these unimposing instruments. Latterly they have been gaining favour with the general public, who up to the present have not fully appreciated their value; many are disposed to regard them simply as "cheaper editions" of the older types of telephones with which they happen to be familiar. This does not do them justice, for they are free from the encumbrances of the latter, and more adapted to being an additional comfort to those who use them. With the introduction of efficient direct working systems, short-distance telephony enters a new stage of its existence. On completing the circuit of a direct working telephone a grating noise is often heard. This is due to an abnormal charge gradually accumulating on the poles of the cells. By giving the batteries some other more constant work to do, or using ones that are already erected for some other purpose, this noise may be avoided.

In Fig. 3 are shown the connections for testing an induction-coil telephone, H, in a similar manner. A separate battery is permanently connected up to the terminals, as also are the "line and return" leads. A pair of receiver cords, with tags at each end, may be conveniently used for making temporary connections to the instrument

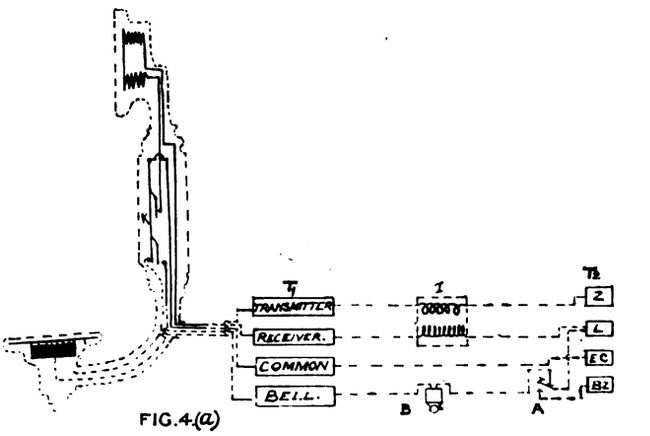

FIG. 4 (*a*)

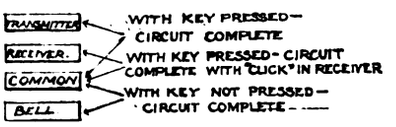

FIG. 4 (*b*)

T1, micro-telephone terminals; T2, telephone terminals; I, induction coil; A, ringing push button; K, speaking switch key; B, telephone bell.

that is being tested, care being taken to make the cords of unequal length, so that the tags will not complete the battery circuit when not in use. To the micro-telephones an undue amount of faults are attributed; these also prove a source of trouble to contractors when they have to place a new one on an instrument. It is not advisable to take them to pieces for any reason; they should rather be returned to the makers. The internal wiring of one for use with an induction coil instrument is shown in Fig 4 (*a*). Inside the telephone there are terminals to which the ends of the flexible cords are attached, as shown; to the right of these is shown a simple outline of the connections inside the instrument to the terminals of the same. It will be noticed that the ringing push-button breaks the local bell circuit when pressed, thus saving battery power; if it did not do so, this bell, and the one at the station signalled to, would be in parallel. The upper end of the "speaking" key is the "common" return connection. When the identity of the ends of the flexible cords is unknown, the end of the "common" connection may be found by the aid of a battery and galvanometer; when this is found the others can be readily identified. In Fig. 4 (*b*) a "key" to the test is given. When micro-telephones have a horizontal transmitter, as shown above, it tends to improve the speaking if they are held in a slightly horizontal position, not quite so vertically as people are disposed to do.

For 10 lines, and perhaps 15 lines, the intercommunication system can be strongly recommended; but it certainly

Digitized by Google

does not permit of being extended indefinitely, as is commonly done. The clumsiness and disadvantages of it increase too quickly; besides, it will be found that there is seldom any real reason for using it on the larger size installations. A better plan is to divide such installations into two separate systems—an intercommunication one for the principals and heads of the departments, the other communicating with a central station only for the use of the employés generally; then, if the principals overhear any business conversation, it is not a matter of much consequence. There is no liability of the employés doing so, as they have no access to the system; the latter are prone to use the telephone for their own convenience or pleasure rather than for their employers' advantage. Again, if the matter is examined more closely, it will be usually found that for routine work the employés generally only require to be in communication with a general office, or some such source of administration. What usually happens is that an outline of the requirements of the proposed installation is given to the contractor; with this the latter sets to work, exerting at times quite an amusing amount of ingenuity. If he can discover names enough for them, that alone is a sufficient excuse for proposing extra stations. The result affords mutual satisfaction, until the purchaser has been deceived so many times by not being able to distinguish which of the neighbouring bells is ringing. Mistakes thus arising, he is provoked to reversing the syllables of the expression he has been using.

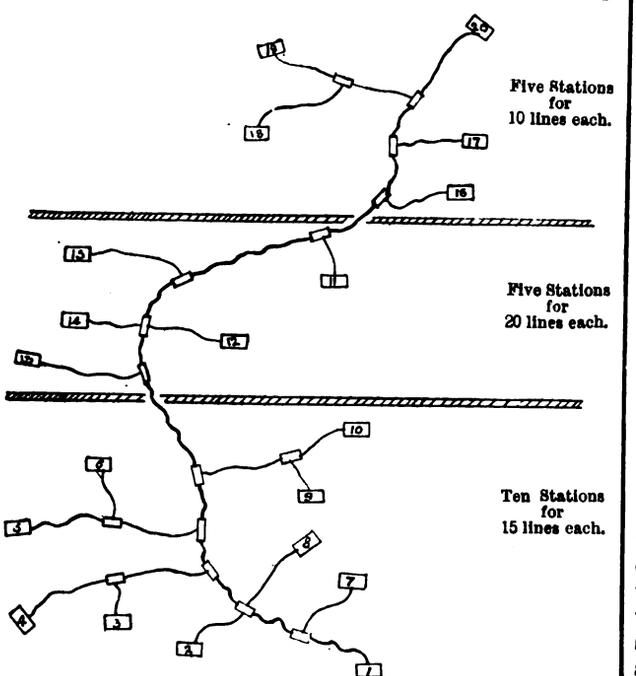

FIG. 5.—Twenty Stations arranged on modified form of the Intercommunication System.

The following original method of wiring is recommended simply as a protest against what can only be adequately termed the *abuse* of the intercommunication system. When the number of stations on the proposed installation counted up amount to, say, 20, the contractor would right away suggest a 20-way intercommunication system. If a little more thought was devoted to examining the routine work of the establishment, it would not be unusual to find that the system could be conveniently divided into, say, three separate systems interlaced (Fig. 5), those stations situated in the administrative part of the establishment being provided with 20-way instruments, those in the second section having, say, 15-way instruments, and those in the third 10-way instruments. Then each station could intercommunicate with all those situated in the same section, and also with those situated in the central section; in other words, the stations in the central section would be able to intercommunicate with all, while those in the other sections would be able to intercommunicate amongst themselves, and be interlaced with those in the central section.

When wiring such telephone installations, the course for the main cable should be decided beforehand, choosing, as far as possible, a diagonal course (as shown in Fig. 5) between the intermediate stations; a considerable length of cable would thus be saved over running them in what generally amounts to a loop round the stations. In a great number of commercial establishments—for example, large factories—such a telephone system could be arranged to be of as practical use as an ordinary 20-way intercommunication one, the central portion in such cases being the general offices, with which all stations require to communicate; the separate departments have, it must be admitted, little intercourse with each other. By adopting this system the cost of the installation would be considerably reduced by lessening the cost of the multiple-cable, and, to a smaller extent, the cost of the telephones. The saving effected over the ordinary method is a function of the degree to which it is found expedient to adopt the system described.

*(To be continued.)*

## ARMATURE REACTION.*

BY EDWARD EUGÉNE BROWN, MEMBER.

In my address to you at the beginning of the session, I promised later on in the session to read a portion which I had left out owing to the length of my paper. When I came to write this paper, I found the subject was hardly to be treated within the limits of the brief time at my disposal this evening. However, I hope, without claiming any originality, to make it sufficiently interesting to the members of the local section.

It was known at an early date in the study of electrical machinery that sparking at the brushes of continuous-current machines was caused by the self-induction of the coil short-circuited by the brush, the brush being placed at the point where the reversal of the current takes place, which is necessary to convert the alternating current into a continuous one, this reversal consisting in the dying out of the current in one direction and the rising of the current to its full value in the other direction. The self-induction of the coil retards the action, and if the circuit of the coil is broken before the action is complete, then a spark at the brush will occur. It was known that, to prevent this sparking, a lead or forward movement if a dynamo, or a backward movement if a motor, must be given to the brush from the neutral or symmetrical line between the pole-pieces. Further, that this movement must bring the coil into a magnetic field, which neutralises the self-induction of the coil, and so prevents sparking.

The subject had been most deeply investigated by the mathematical physicists, and equations with numerous constants to be determined by experiment were offered to the designer, but none of these were in a useful form, and, moreover, they did not agree, giving such various values as to be useless; and even now, although the subject has been skilfully handled, and is in a form that is extremely useful to designers, it cannot yet be said to be complete. The *a priori* calculation of the self-induction of a coil of such a shape as an armature coil is very difficult, depending as it does on the permeability of the medium surrounding the coil, the varying shape of the coil, the mutual induction in neighbouring coils, its position in the slot, and the shape of the slot; but it has been demonstrated that the self-induction does not alter its value to any great extent whether the armature is moving or still—this has simplified very much the calculation. We wish to determine then what is the number of lines linked with the turns per ampere? Various values, deduced from experiments, have been given—those by Mr. Hobart as four lines per ampere per centimetre length of the embedded part of the coils, and ·8 lines for the free ends of the coil. From these values can be worked out the inductance and the E.M.F. of the coil, or the reactance voltage, as it is termed, from the formula

$$2\pi n L C = \text{reactance E.M.F. in volts,}$$

where L = inductance in henrys;
C = current in the coil;
$n$ = frequency of commutation;
$2\pi n L$ = reactance in ohms.

* Paper read before the Newcastle Local Section of the Institution of Electrical Engineers, May 15.

Digitized by Google

This formula supposes that the current in the coil falls as a sine curve, and this is doubtful—any variation may alter the value very much. This formula has been simplified by Mr. Mavor to

$$\text{Reactance voltage} = \frac{E\,C\,f\,m}{d\,F},$$

where E = total E.M.F. generated in armature in volts;
C = total armature current in amperes;
$f$ = induction field in C.G.S. lines per centimetre per length of slot due to one turn;
$m$ = armature turns per commutator section;
$d$ = diameter of core measured;
F = average flux taken over the whole of the surface of the armature in C.G.S. lines per square centimetre.

Or again, $\text{Reactance voltage} = 2\,\pi\,n\,(e + \cdot 1\,f)\,\frac{E \times C}{F}$,

where $e$ = embedded length of conductor;
$f$ = free length of conductor;
F = armature C.G.S. lines.

It is not actually decided what is a satisfactory value for the reactance voltage, except that it should be as low as possible and probably not higher than six volts as a maximum. If below three volts, and the machine has other good constants, the brushes may be placed in the neutral zone, and will run sparklessly—without movement from no load to even an overload.

There is the limit of reduction to all the factors which make up a low reactance voltage when we arrive at one turn per section, and have made the armature as short as possible, so that if the speed is high we cannot keep the reactance voltage low enough so as to be neutralised by the carbon brushes; or if the speed is too high to prevent the use of carbon brushes, owing to the difficulty at such a high speed in securing a good contact with the rigid surface of the carbon, then we must rely upon moving the brushes, so that the coil is in a fringe of the field, to get a reversing E.M.F. to oppose the self-induction voltage of the coil. At no load this fringe of the field would cause sparking, as there is no reactance voltage to oppose it, so that fixed position of the brushes cannot thus be obtained. Moreover, it is found that as the load increases so must the brush be moved forward. This is caused by the field necessary for commutation moving away in the direction of rotation as the load on the armature increases. So that, unless the reactance voltage can be kept very low, we must take means to keep down the armature reaction which causes the distortion of the field.

The contact resistance of the brush is an important factor in commutation. With metallic brushes, such as copper gauze or even brass gauze, this resistance can be but little relied on to keep down the short-circuited current or to allow it gradually to reduce before reversing. For this purpose carbon brushes are mostly used. These can be made of various specific resistances, or varied in resistance in their thickness, so that across the thickness they have a very high resistance, but longitudinally they have a low resistance. The density at the surface cannot be anything like as high as that of metallic brushes—not more than 50 amperes per square inch as a maximum, 30 amperes being mostly used, but lower is preferable. If run too high, they get red hot at the tips and disintegrate. Mr. Hawkins gives a formula which includes the brush contact, R:

$$\frac{R\,T}{L} > 02 \text{ as a minimum,}$$

where T = total time of short-circuit in seconds;
L = self-induction in henrys.

The numerical part often reaches 2 with carbon brushes, but should not be less than 1; but, of course, the number has to be decided by the conditions in any individual case, depending upon the current and voltage, the volts between the commutator segments being an important factor in commutation.

With the high speeds used for turbo-generators it is impossible to keep down the reactance voltage, and this is the reason why I have brought the subject before you as interesting at this time. Whilst the speeds are kept low, as in dynamos coupled to ordinary reciprocating engines, there has been little necessity for considering means for reducing armature reaction, carbon brushes fulfilling every requirement.

The conductors on an armature act like a separate magnet opposing the field magnet, but it is preferable to regard the whole magnetic circuit of the field magnet and armature as one, the conductors on the armature being so disposed that they form a belt, which tends to distort the magnetism in the gap where the armature revolves. If the brushes are given a lead, then the conductors between the double angle of lead—that is, on each side of the neutral line—act as demagnetising turns opposing the field. In the old two-pole smooth-core dynamos we used to take the value of these back turns as one-sixth of the ampere-turns on the armature, but, of course, as it depends on the amount of lead, it should be determined for each winding, and can only be approximately calculated, but near enough for practical purposes.

Some writers treat the subject by calculating the lead as if just under the forward pole-piece, but a dynamo with so great a lead could hardly be satisfactory; the lead should never be greater than half the distance between the neutral point and the tip of the pole-piece, but the shape of the pole-piece has great influence on the lead. In slotted cores the reaction is generally greater than in smooth cores, but the saturation of the teeth will prevent excessive reaction. These back or demagnetising turns can be compensated for by increased field winding, either from the shunt or series coil. The conductors at right angles to the belt of back turns form the distorting or cross magnetising turns. These are the turns which drive away the field from the leading pole-tips, and so necessitate the continual movement of the brushes, the leading tip is weakened and the trailing tip strengthened, the induction being driven across the pole from one side to the other.

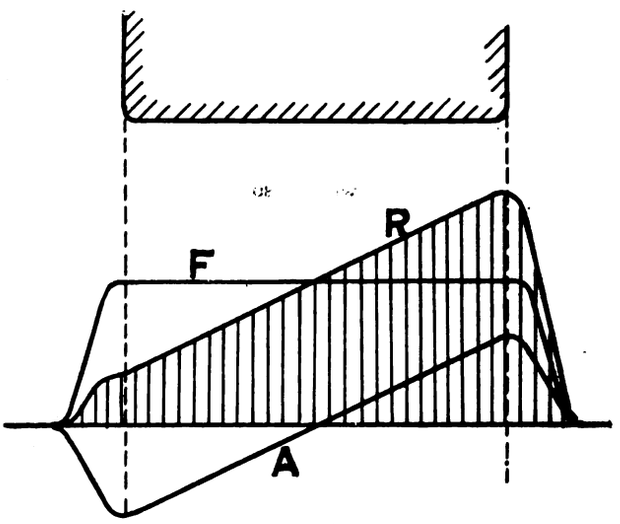

FIG. 1.

The diagram (Fig. 1) shows the resultant curve from the induction on the field and the cross induction of the armature ampere-turns. Assuming that the induction is equal on every part of the pole-piece, the field due to the magnets is shown by the Curve F, that due to the cross magnetising turns on the armature by A, and the combined Curve R by the shaded part; it will be seen how very much diminished the induction is in the leading pole-tip, and may be so much weakened as to render commutation impossible. Fig. 2 shows the result of too large a load on the armature, increasing the cross magnetisation till the field for commutation is in the wrong direction. A slot parallel to the path of the lines in the middle of the pole-piece, putting reluctance in the path of the distortion, would alter the curve materially, and might cure a sparking machine by furnishing a positive field at the point necessary. This is shown in Fig. 3, and is the same machine as shown in Fig. 2, but with the magnet slotted through.

Various ways of shaping the pole-shoes have been used—by diminishing the pole area so as to concentrate the induction, or boring the armature space elliptical so as to

Digitized by Google

have a greater bore at the tips than at the middle, tending to throw the lines further out towards the neutral zone, thus providing a field for commutation without excessive lead. In connection with slotting the pole, a good design is to form the magnet of a multipolar into separate horseshoes, which would be like slotting the poles right through. These separate magnets could be quite short and the coils close to armature, preventing leakage. But the most successful alteration to the magnets is to provide auxiliary poles, forming a field exactly at the place required by the coil that is being commutated. These extra poles should be in the circuit of the armature, so as to provide a field increasing with the armature current to counteract the reactance voltage of the coil, permitting the current in the coil to reverse properly. It is necessary to scheme these additional poles so that the leakage is minimised, as they would tend to largely increase the leakage of the main magnets.

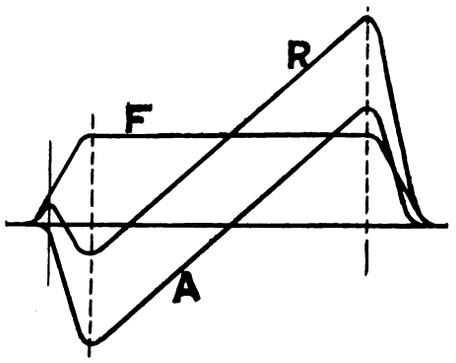

FIG. 2.

An ingenious method has been used by Mr. Sayers of introducing some extra turns on the armature, which are not in the armature circuit as a whole, but are between the commutator segments and the armature coil. As these additional turns are wound somewhat forward from the short-circuited coil, and in the neighbourhood of the pole-tips, they get the necessary field to neutralise the reactance voltage of the coil. It is difficult to see how this can work satisfactorily, as at small loads it provides the field where it is not wanted, which would cause sparking; in fact, the additional coil alone has not solved the problem, and extended pole-pieces have been used in conjunction with the device.

To wind coils round the armature in as close proximity as possible so as to neutralise the cross magnetisation has been often proposed. There are considerable structural difficulties. An early attempt was in a machine made by

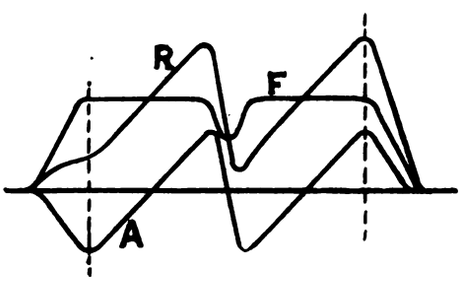

FIG. 3
